Prince Edward Island, a province of the Dominion of Canada, N. America, lies in the S. of the Gulf of St. Lawrence, and is separated on the S. and W. by Northumberland Strait from Nova Scotia and New Brunswick. The latitude is about 45° 56'–47° N.; the longitude 62°–64° 23' W. The island is crescent-shaped, 130 miles long, from 4 to 34 broad, and has an area of 2173 sq. miles. Pop. (1871) 94,021 (Indians 302). An isthmus 4 miles wide joins the smaller western portion to the rest, and 24 small islands also belong to the province. The red sandstone cliffs, from 20 to 100 feet high, which encircle the island, are broken by many inlets, of which Cardigan Bay on the E. and Hillsborough Bay on the S. are safe ports for large vessels. Bedeque, Cascumpec, Malpeque, New London, and Murray harbours are also considerable, and there are very many lagoons. The surface of P. E. I. is slightly undulating, the chain of hills which crosses the country seldom exceeding 300 feet in height. The rivers are very numerous, and the soil, which is generally a layer of vegetable matter above light loam resting on the stiff clay underlain by Silurian sandstone, produces of cereals, fruits, and vegetables about twice as much as is needed for home consumption. Cattle, horses, swine, and sheep are extensively bred. The climate is milder than that of the mainland in the vicinity (the range of temperature in 1874 being from 88° to 18° F.), and is especially favourable to wheat-growing. Of the whole area of the island, amounting to 1,365,400 acres, only 52,252 are uncultivated; but agriculture has improved greatly since 1854, when the provincial government commenced to buy up the great landed estates, and to re-sell them to small well-to-do farmers. The exports in the year 1874–75 amounted to £272,596, consisting chiefly of oats (£151,945), fish (£64,174), timber (£21,976), eggs (£12,129), and vegetables (£10,421). The imports in the same year amounted to £408,541, being mainly iron and hardware (£75,853), woollens (£54,967), tea (£34,289), cottons (£33,966), and spirits (£9033). The number of vessels entered and cleared in 1874 amounted to 100,597 tons (39,631 British). The tonnage registered in the island on December 31, 1876, was 50,677 (355 vessels). Shipbuilding is carried on to a considerable extent, but the formerly magnificent forests of birch, beech, maple, elm, ash, pine, spruce, fir, juniper, cedar, willow, and poplar are vastly reduced. Cloth is made, but the manufactures are trifling. Few valuable minerals are known to exist, only copper and bog iron being found, and in but small quantities. The peat-bogs are easily converted into hay fields, and the fisheries, mainly of mackerel, herring, and cod, are exceedingly rich. P. E. I. is divided into three counties, King's, Queen's, and Prince, of which the respective capitals are Georgetown, Charlottetown (capital of the Province), and Summerside. In 1874 there were 355 schools in operation, of which 18 were grammar schools. The number of pupils was 16,292, and of teachers 453. There are also several private schools. Higher

education is provided in 'Prince of Wales College' (Protestant Episcopal), 'St. Dunstan's' (Roman Catholic), and the Wesleyan College, all at Charlottetown. Except in the colleges, tuition is free, the outlay from the colonial treasury upon education in 1868-69 being £19,793. P. E. I., discovered by the Cabots in 1497, began to be settled in 1715 by the French, who named it the Isle St. Jean. It fell under English rule in 1764, and many of the French left. The island was then apportioned to 67 grantees, who agreed to colonise it with numerous non-English Protestant settlers. These conditions they never fulfilled, yet the British Government, in spite of popular discontent and the hindrance to material progress, maintained them in possession till 1854, when it commenced to force a sale of the large estates. Things are now much better. The Roman Catholics, never fully tolerated till 1830, have a bishop at Charlottetown, and form the most numerous religious body in the island (40,442 in 1871). P. E. I. first received its present name in 1798, in honour of the Duke of Kent, father of Queen Victoria. It became a part of the Dominion of Canada in 1871, and sends six members to the Dominion Parliament.

Prince of Wales, the principal title of the eldest son, or, in the event of his death, the grandson, of the reigning sovereign of England, but not necessarily of the heir-apparent to the crown, e.g., James I., William IV., or Ernst August of Hanover. The last native who held it was Llewelyn ap Gruffyd (1246-82), two years after whose death it was conferred, so runs the story, by Edward I. on his second son, in fulfilment of his promise to the Welsh chieftains that he would give them a prince born in their midst and unable to speak a word of English. Presenting to them the infant Edward of Caernarvon, he pronounced the words *Eich Dyn* ('This is your man'), the origin of the motto *Ich dien*, which another tradition refers with equal probability to the German motto *Ich diene* ('I serve') of King John of Bohemia, slain by the Black Prince at Cressy (1346). As a matter of fact, Edward II. was not created P. of W. till 1301, nor was the title ever borne by his son, Edward III., being first revived in the person of the Black Prince in 1343. Since him it has been bestowed on fourteen heirs-apparent by patent, investiture, or proclamation; but like him, five out of these fifteen have never succeeded to the throne—Edward, son of Henry VI., slain at Tewkesbury (1471); Edward, son of Richard III. (died 1484); Arthur, elder brother to Henry VIII. (died 1502); Henry, son of James I. (died 1612); and Frederick Lewis, father of George III. (died 1751). Edward VI. and Charles II. seem never to have been invested with the dignity, and it is a moot question whether Mary was or was not styled Princess of Wales in her own right up to the birth of a son to Henry VIII. Neither of course was the title borne by the six sovereigns who came irregularly to the throne (Henry IV., Edward IV., Richard III., Henry VII., William III., and George I.); so that the curious fact remains that out of the twenty-three kings of England since Edward I. only twelve have been Princes of Wales. To the principedom of Wales are annexed, in England, the duchy of Cornwall and earldom of Chester; in Scotland, the duchy of Rothesay, earldom of Carrick, barony of Renfrew, and lordship of the Isles, with the titles of Prince and High Steward of Scotland; and in Ireland, the earldom of Dublin. By 26 Vict. c. 1, an annuity of £40,000 was settled on the P. of W., to whom in 1877 the sum of £70,375 was paid over, including £29,452 from the revenues of the duchy of Cornwall. The same statute further settled £10,000 on the Princess of Wales, to be increased to £30,000 in the event of her widowhood. See *Doran's Princes of Wales* (Lond. 1860).

Prince of Wales Island. See PENANG.

Princeton, a small town in New Jersey, U.S., 49 miles S. of New York. It is the seat of the College of New Jersey, founded by the Presbyterian Synod of New York at Elizabethtown, New Jersey, in 1747, and removed to P. in 1757. In 1875 the college had 483 students, and endowments to the amount of \$600,000. The Presbyterian Theological Seminary, founded in 1812, had, in 1878, 114 students. It is under the supervision of the famous Dr. Hodge, author of *Systematic Theology*. P. was the scene of a battle, 3d January 1777, in which the Americans under Washington defeated a part of the army of Lord Cornwallis. In 1783 the Continental Congress assembled here. Pop. 3986.

Prince Rupert's Drops, so named after their discoverer (see RUPERT, PRINCE), are formed by dropping molten glass into water, when they are almost immediately solidified. They have a general resemblance to tadpoles, and resist pretty violent hammering on their thick end. The nipping off of the smallest fragment of the tail, however, at once reduces the whole to fine powder. The change takes place violently and with an appreciable evolution of heat. The explanation is that the mass is in a state of strain, so that the arrangement of the molecules is very unstable. The only stable portion is the outside film which had hardened before the rest had time to cool. Break the continuity of this film at any part, and the drop, free from restraint, is shattered by the violence of its pent-up energies. Bologna's phial acts in exactly the same way. It is shaped like a test-tube with thin walls and thick extremity, and has been rapidly cooled by immersion in cold water. A round, smooth body may be dropped into it from a considerable height; but the slightest scratch by a sharp irregular fragment is at once followed by dissolution of the whole.

Prince's Metal, or **Prince Rupert's Metal**, is a kind of brass, being an alloy of copper and zinc in the proportions of three to one.

Principal (in music), the name of the chief open metal stop in English organs, 4 feet in length on manual, 8 feet on pedal. The pitch is one octave higher than the diapasons. We speak of the P. violin or vocalist in a musical performance, and of the P. theme in a composition.

Principal and Accessary. In criminal law a principal is either the actual perpetrator of a crime, or one aiding at the spot of commission, or in its neighbourhood. See ACCESSARY.

Principal and Agent. See AGENT AND FACTOR.

Principal Surety. See GUARANTEE, CAUTION, &c.

Printers, Law Regarding. A printer has no right to publish a work in his hands. He has, however, a *Lien* (q. v.) on the printed sheets for the price of his work, and on the last sheets undelivered for the price of the whole. It has even been decided in England that his lien for the price of volumes delivered extends over undelivered volumes. 32 and 33 Vict. abolish certain former statutory restrictions on printers and typefounders. A printer must print his name and address on every book or paper issued by him, under a penalty of £5 for each omission, if sued for by the crown. The mere printing of immoral matter is probably not contrary to law, but the publication is. See OBSCENE BOOKS. See also COPYRIGHT, LAW REGARDING.

Printing, Letterpress, the art of producing one or more impressions from types or stamps, bearing a reverse image of that from which a copy is desired, as it now exists, cannot be said to have a very long history, yet there is no question but that some idea of the process prevailed many centuries ago. Long before the Christian era, as relics from Assyria and Babylon as well as from Egyptian cities show, bricks and cylinders were stamped with symbolical figures and hieroglyphics, preserving till now the history of their country and the records of their attainments, being at once manuscripts and pictures—illustrated books, so to say, speaking alike to eye and to mind. These impressions, especially in the Egyptian bricks, were produced with wooden blocks carved in the required manner and stamped upon the plastic clay, the hollow being occasionally tinted with a coloured pigment. These bricks are not the only evidence we possess of there having existed in Egypt an idea of this method of taking impressions—the signet-rings of the Egyptians, and other articles, such as smooth wooden boards rubbed over with wax, leaves and bark from trees, skins and intestines, as well as the soft cellular tissue of the papyrus, prove it. The Greeks and Romans also made use of stamps with the characters reversed—one especially exists, the signet of C. Cæcilius Hermias, cut in bas-relief, which, if covered with ink, would leave an impression similar to our modern type. The Chinese again, a people whose civilisation early reached a point far beyond that of any other, had ages ago a system of printing which might easily have developed into a method similar to that now in use; but fruitful as the Chinese were in rudimentary ideas, they do not seem to have had energy to advance farther. Long before printing was known in Europe they had invented a method

of wooden block-printing of their own, which nevertheless stagnated in stereotyped editions of the works of Confucius. It is believed that it was in the 10th c. they first began to print, but an old Chinese work contains a passage to the effect that on the 5th day of the 13th year of Wen-ti (593) it was ordered by a decree that the old worn-out drawings and inedited texts should be collected that they might be engraved and published. 'This was,' says the work referred to, 'the commencement of printing from wooden blocks.' As early as 904, blocks of stone were used, on which the writing was engraved—a method of printing by which the ground of the paper was made black, and the writing left white. The general method, however, was by means of wooden blocks. The text to be printed was first written on thin paper, which was fastened face downwards on the block, and the characters being legible through the paper, the surrounding parts were cut away, and the words left in relief. These words being inked over, the paper was laid on, a soft brush gently applied, and the process was complete. Each page of a book would of course by this method require a new block, and could only serve for the one unvarying purpose, not being, like types, susceptible of a new arrangement. This process, with the characteristic conservatism of the Chinese, is still maintained to this day, though movable types are now being gradually introduced; but an almost insuperable difficulty exists in their language, which has not an alphabet made up of a few characters by which any book may be printed, a separate type being required for almost every word.

A similar method of printing from wooden blocks having been the first pursued in Europe, has very naturally led to the conjecture that the idea came from China; but this is not likely to have been the case, as at the time of its introduction there was very little intercourse between that country and Europe. It was not until long after the return of Marco Polo from the East, to whom some authorities give the credit of having brought the art from China, that the first attempts at block-printing were made in the production of rude pictures of saints, and also of playing-cards, the impression being taken by placing the paper upon the inked block, and rubbing the back with a burnisher. From this the transition was easy and simple to productions of another kind. The earliest book-prints of this nature were usually of a sacred or devotional character, and were of two classes—books of pictures without text, and books of pictures with text, being thus more artistic than literary, and generally printed in a dull, rusty-brown pigment or ink. One only exists which has any certain date, and is a representation of St. Christopher carrying the infant Saviour across a water, bearing the date 1423, which was found in a German convent, pasted within the cover of a Latin MS. of 1417: this print eventually came into the possession of the Spencer family, and the volume containing it was on view at the Caxton Exhibition in 1877. Following this came the curious work called the *Biblia Pauperum* (q. v.), or *Bible of the Poor*, of 40 pages, printed on one side of the paper only, in a brownish ink, the blank backs being pasted together. It resembled children's toy-books, having an illustration with texts and explanations on each page. The *Biblia Pauperum* is the most famous specimen of the early block-book, and seems to have received its name to distinguish it from the Bible proper, a fair MS. copy of which in France, about 1460, sold for 400 crowns of gold. It was followed by the 'Image Books,' such as the *Apocalypse*, the *Canticles*, the *Eight Rogueries*, &c., some of which are still extant, and are of great value as curiosities. The block-books did not altogether go out of fashion when types were invented, as some were printed so late as 1512, but they gradually deteriorated in merit, and in the course of the 16th c. became practically obsolete. The cutting-up of these blocks into their separate words was next thought of, so as to be capable of new arrangement, and thereby forming fresh pages.

This brings us to the year 1438, and to Gutenberg (q. v.), to whom the invention is generally attributed, and who was previously occupied in the production of prints from wood blocks at Strassburg, which city he left for Mainz between 1444 and 1448, where he entered into partnership with Fust (q. v.). The Dutch, however, make a claim in favour of Laurens Koster (q. v.) as being first in the field, maintaining that he invented the process as early as 1420 or 1426. Koster copied closely the MS. writing of the clergy, whose productions he imitated even to the abbreviations, and this may account for his name not appearing on his books. He worked in secret at

first; till, his custom increasing, he required to take an apprentice, who (according to the Dutch), at Koster's death in 1439, purloined his types, fled to Mainz, and gave the secret to Gutenberg. There is a proof at least of the independent nature of Koster's work in the fact that some of his books resemble the Dutch handwriting of the first half of the century, and also that they are printed on one side of the paper only, like the first proofs of a beginner, while those of Gutenberg are in a more finished style, and are models of impression. Four names have figured in the controversy in regard to the first printer by means of movable type, and the cities of Haarlem in Holland, and Mainz and Strassburg in Germany, all claim to be its birthplace. Those who favour the theory of an invention of typography in Holland refer to the *Speculum Humane Salvationis*, a very curious book, popular as a MS. two centuries before type-printing, which dates as a printed book from about this time, and is generally believed to be the work of a Dutch printer. It consists of pictures with descriptive text printed on one side of the paper—the first twenty pages from wooden blocks, in brown ink of glutinous quality to prevent it from spreading, the remainder being in brown ink also, with the text below in black, evidently from movable type, so that it is by no means impossible that printing was independently invented both in Holland and Germany; for whoever printed that book had evidently passed from 'the shoals of experiment to the broad sea of successful practice.' Besides the *Speculum*, there are a number of fragments of other books printed from movable types, which can scarcely be looked upon as the production of men who learned the art from Gutenberg; but the probability is in regard to Koster, that he was among the earliest to practise block-printing, and that he never attempted the system of movable type. It is, therefore, to Gutenberg, Fust, and Schoffer, 'the Grand Typographical Triumvirate,' as they have been termed, that we must look for the first use of movable type, primarily of wood, and then of metal. Strassburg puts forth its claimant in the person of John Mentell or Mentellin, whose tombstone bears the following inscription, carved beneath the figure of a printing-press: 'I repose here, John Mentellin, who, by the grace of God, was the first to invent in Strassburg the characters of printing, by means of which a man may write more in a day than formerly in a year.' He is now generally believed to have gained his knowledge of the art from Gutenberg before the latter left Strassburg, and neither Mentellin's books nor the records of Strassburg give warrant to the hypothesis that he was the inventor of printing. The goldsmith Fust, according to one German antiquary, was first indebted for his idea of the art to seeing the footprints of a horse on the soft mud of a road on which he was walking. He went home thinking on this circumstance, and 'from that day printing was invented.' Little value, however, is to be attributed to this story, as in all trustworthy evidence Fust only appears as the capitalist by whose pecuniary aid Gutenberg brought the art into working operation. The goldsmith and his associate worked long in secret at the wooden blocks with which Gutenberg commenced, till Schöffer, an illuminator of MS. and a confidential person in their employ, hit upon the expedient of the punch and matrix, by which types were cast in separate single letters—this being the greatest step in advance of the science of typography, and the fundamental basis of the new art. The first book they printed on the new system, passing over some small ones which are of doubtful authenticity, seems to have been the *Biblia Latina Vulgata*, generally known as the 'Mazarin Bible,' on which they expended 1200 florins before they had produced twelve sheets, and which was not completed within three years. This, the first perfect book ever issued, was a folio in two large volumes, of 637 leaves, printed in large Gothic or German characters, now generally called *Black Letter*. The same year that the Latin Bible was finished (1455), Fust took Gutenberg to law for repayment of money lent to further the work, and the printer not being able to pay his debt, was deprived of his press and printing materials. Shortly after, Gutenberg, with the aid of Konrad Humery, Syndic of Mainz, began anew, and issued in 1460 the *Catholicon*, a folio volume of 373 leaves. The art began to be made public about 1462, and gradually spread throughout Europe; but so slow was its progress that at the close of the century not more than 200 presses were at work.

The method used by these early printers for applying the ink

to the types was by means of hand-balls of skin stuffed with wool, a plan which continued with little modification till within the last forty years, when they were superseded by the 'rollers' now in use. For many years the old Gothic or black letter was the uniform type used, till in 1465 an edition of Lactantius was printed at Subiaco in a kind of semi-Gothic of great elegance, and approaching very nearly to the present Roman type. Two Italian brothers named De Spira (1469) acquired a high reputation for the beauty of their printing and the fineness of their type, so much so that printers at Rome and elsewhere furnished themselves with similar founts of type. The perverted taste of the time, however, compelled these printers to again change in 1477 their beautiful Roman type for the old and disagreeable Gothic, an example in which the De Spiras were followed by Nicolas Jenson, a Frenchman following the occupation of a printer at Venice, who is said to have brought the art to its utmost perfection. The attempt to use the Roman character was also made by Gering, a printer who had established himself in the Sorbonne at Paris—his works being all done in a handsome type, imitating the character of the Augustan age. In 1483 this printer also found himself obliged to discard the Roman type and conform to the prevailing fashion by using the 'clumsy and ill-formed Gothic,' being compelled to 'sacrifice taste to interest, and comply with the perverse inclinations and prejudices of the age,' arising very much from the preference the learned then showed for the old character from its resemblance to the writings of the old monks, which were held in great veneration. The introduction of the new type, however, would not be hindered, for not many years after we find Jean Petit, another Parisian printer, using types 'commonly denominated Roman,' and also occasionally a species of semi-Gothic and abbreviated characters, formed in imitation of MS., and much in use among the early French printers. In France, more perhaps than in any other country, resistance was displayed to the new art—the MS.-writing clergy bringing all their influence to bear against it, fearing the loss of their power as well as their means of livelihood. See TYPES AND TYPEFOUNDING.

Title-pages to books were first used about 1480. None of Caxton's books have any, with one doubtful exception, but titles to chapters were employed as early as 1470, appearing first in an edition of the *Epistles of Cicero*. Ornamental title-pages came in about 1490, the usual embellishment at first being a figure of 'the author at his desk.' Signatures, or letters at the bottom of the first page to guide the bookbinder in the arrangement of the sheets, began with a Terence printed at Milan in 1470. Catch-words, now altogether disused except in law-papers, were first applied to printing by De Spira at Venice, and the earliest system of numbering was applied to leaves, not to pages, a figure being placed at the top of the *recto* in each leaf. The only marks of punctuation at first used were the comma and full stop; Aldus improved upon this by giving a better shape to the comma, which till his time was only an oblique stroke, and also added the semicolon.

Caxton, the first English printer, is believed to have gained his knowledge of the art while in Bruges from Colard Mansion, one of the fugitive workmen of Fust—who had found it expedient to leave Mainz, owing to that city being involved in some of the Continental wars. Claims have been urged in favour of Friedrich Corbellis, a German, who had his press at Oxford, as the first who printed in England, from a book with the date of 1468 having been found which is supposed to be his work. But experts who have examined the book agree that from its style and workmanship it could not have been printed so early, but probably ten years later, and that the workmen omitted an x in the title date, an error of which this is by no means a solitary instance. The first work published by Caxton with Mansion's aid was the *Recueil des Histoires de Troy*, a book which he had translated and circulated in MS. some years before. It was followed soon after by *The Game and Playe of Chess*. Returning to England in 1476, he soon after set up his press at Westminster, and early in the following year published the first book ever printed in this country, *The Dictes and Sayings of the Philosophers*, a folio of 76 leaves. No fewer than 54 books are known of Caxton's, and 'the total produce of his press,' says Blades, 'not reckoning the books printed at Bruges, reaches to above 18,000 pages, nearly all folio size,' one of which at least was written and 22 translated by himself. He printed in a mixture of 'Secretary' and Gothic type, designed to imitate the hand-

writing of the time, and seems not to have been able to procure, or may have rejected, the Roman letter, even after it had been used with excellent effect by Continental printers. His successor, Wynkyn de Worde, showed great skill in his art, and is believed to have cut punches and cast his own type, and was the first to introduce the Roman letter into England, making use of it originally to distinguish any emphatic word or phrase. De Worde was also the first to use Greek letters in this country (1519), these being at that time cut out of wood. Richard Pynson, an associate of De Worde under Caxton, set up a press of his own at Temple Bar, and in 1499 published a book called *Promptorium Parvulorum*, in which he used a type equalling, if not excelling, in beauty any produced in modern type-foundries. After the days of these Caxtonian associates the art progressed with giant strides in this country.

The earliest book in which both printing and engraving are combined is a Dante, published at Florence in 1481, and from that city came also what is known as *Italic* types, an imitation of the *curvive* character then in use at the Roman chancery. These have also been called Venetian letters, from the punches from which the types were cast being cut at Venice. The earliest specimen of printing in Scotland is *The Porteous of Noblesse, translated out of Ffrenche in Scottis* (Edin. 1508), a licence having been granted by James IV. to two merchants in that city to establish a press in 1507. The progress of the art in Scotland must have been slow, as in 1574 the Privy Council found it necessary to levy a contribution of £5 from each parish in the kingdom to enable Thomas Bassendyne to print an edition of the Bible. He became bound under penalties to deliver copies 'weel and sufficiently bund in paste or timmer' for the sum of £4, 13s. 4d., the remainder of the enforced contribution being detained to defray the cost of collection. Having 'guid characters and prenting irons,' the Council thought the work, great as it was, would go quickly on. The hope was not realised, for Bassendyne found it necessary to petition for longer time in 1576; and in the following year he was ordered by the Council to deliver up his printing-office and Bible to Alexander Arbuthnot, who finished the work and had it in circulation in 1579. The sale of this work was rather enforced, for the Council soon after enacted that all persons worth £500 should possess a Bible in the vulgar tongue, under a penalty of £10.

Printing was first practised on the Continent of America in the city of Mexico by Juan Cromberger, between 1536 and 1540, the latter year being the date of the earliest printed book from Cromberger's press. The second press was put up by Stephen Daye at Cambridge, near Boston, U.S., and the first work issued was *The Freeman's Oath*, dated 1639. In 1785, Mr. Wilkins, a young Indian merchant, translated the *Bhagavadgītā*, and soon after the *Hitopadesa*, being the first to print in the Sanskrit character, actually casting his own types. The history of the art need not be followed further; its onward progress has been rapid and successful.

Turning now to the practical details of the art, the workmen employed are known as compositors and pressmen or machine-men. First in order comes the 'compositor,' who arranges the types into lines, and then into pages. Reckoning that there are rather over 60 separate pieces of metal, appearing and non-appearing, in a single line of this work, there will be about 10,000 in the page, it follows that considerable skill and patience are required in the process of setting up the types, which are contained in two 'cases,' mounted one higher than the other in a sloping position on a high stand or 'frame.' The diagram annexed shows the 'lower-case' in common use, with the

Lower-Case.

arrangement found most suitable for the various types, those most in use being nearest the hand, the boxes containing no

letters in the cut being set apart for the spaces, which are put between the words, and fill up the blanks at the ends of short lines. The upper-case is of the same size, but the boxes in it are smaller, are equal in dimension, and number 98, containing CAPITALS, SMALL CAPITALS, accents, &c. The compositor, standing in front of the cases, with the author's MS. or 'copy' before him on the upper case, picks up letter by letter the words in his copy and ranges them in his 'composing-stick,' which is

Composing-stick.

adjusted to the width of the line by a small screw, each type having a small notch in front to show him how to place it, 'justifying' or spacing-out to the proper width each line as it is completed. Proceeding thus, he gathers together, line upon line, page after page, till sufficient is in type to make a sheet of the work in progress. It is then put into pages, and placed in the proper position for printing within an iron frame or 'chase,' with wooden 'furniture' between and round the pages to allow the proper margins at back, front, top, and bottom of the book. The 'forme,' as it is now termed, is then taken to the press, where a 'proof' is printed, handed to the 'reader,' who with the aid of a boy compares the author's MS. with the printed proof, and marks the errors in spelling, punctuation, &c. After these are corrected, the reader again revises the proof, when it is sent to the author, whose alterations having been given effect to, the types are prepared for finally printing.

During the last half-century many attempts have been made to introduce type-composing machines, but for various reasons these have never yet attained complete success—one requiring special types cast for it, another proving not cheaper in labour, while a third was so complicated and fine in its details that mishaps were daily occurring; and, generally speaking, the working of such machines has been found even more irksome and fatiguing than the ordinary work of a compositor. One of the earliest type-composing machines was that invented by Sorenson, a Danish printer, and exhibited at the Great Exhibition of 1851. It has been adopted in various Continental offices, but has the defect of the types requiring a special notch. The 'compositor' of Mr. Hattersley of Manchester was first patented in 1857, but has since gradually been improved. In his machine the types are placed in metal boxes placed horizontally over the top, and divided into numerous rows by strips of brass, each row containing a separate type. Rows of keys, marked with a letter or other sign, are in front of the machine, and when one of these keys is depressed by the compositor, a type is pushed from the corresponding row down through the tubes of a V-shaped guide-plate into a slide below. The types are thus set up in one long line, and are then passed into the composing-stick and justified to the proper width of line. In 1865 Mr. Mackie took out patents for composing and distributing machines—the distributor required, however, a special notching of the type, and from this cause so far has not met with the success which its ingenuity merited, and thus has been practically a comparative failure. His compositor has been more successful, and is in use in various parts of the country. It consists of two distinct parts—the first being fitted with ivory and ebony keys like a cottage piano, and manipulated very much in the same way. The copy being placed where the pianist would put the music sheet, the workman spells out his copy upon the keys letter by letter—each touch of a key causing a small round perforation in a narrow strip of paper of unlimited length; and so quickly can this be done that an average of about 15,000 perforations has been attained in an hour. The perforated strip is now taken to the second machine, which looks like a round table with a series of upright boxes or pockets fixed upon its outer edge all the way round. These upright pockets contain the types, eight kinds in separate compartments of each box; and on a wheel underneath are a number of little platforms having a row of holes through which pins or 'pickpockets' project from below. The wheel

being made to revolve, as the perforated paper goes round with it, the pins pass up through the holes and pick out the letters corresponding to those with which the first machine perforated the paper. Eight separate letters being in one pocket, it happens sometimes that when the paper shows three, four, or five perforations in a line across, that a whole word will be picked out at once by the pins. As the wheel in its revolution reaches a certain point, the gathered words are carried away on a band and deposited in a long line, from which they are taken up and justified to the proper measure of the page.

Another of these composers is that of Kastenbein, which is now in use at the *Times* office. Like Hattersley's, than which it is more compact, the types are placed in long metal tubes lying over the top of a heart- or V-shaped conducting-plate, with rows of keys for each letter or sign below. The keys being touched, the types are withdrawn from the tubes above, and falling by their own weight through the channels in the guide-plate, are received at the bottom in a long line, from whence they are taken and justified. The lighter letters, such as *i* and *l*, are placed right over the opening of the conducting-plate, giving only a short distance to travel, while the capital *W* is placed farthest away, as the latter having greater momentum might arrive otherwise too soon at the bottom, and come in where it was not wanted. One column and a quarter per hour is the nominal rate of the type-setting by this machine, and several are in daily use in the *Times*, where it is frequently put to a novel use: being placed close to a special Continental telegraph wire, as a message is received from abroad, it is read off by the telegraphist and set up at once from his dictation. Kastenbein is the only one who has succeeded in attaining anything like success with the distributing machine for returning the letters to their places when done with. The types to be distributed are placed at the top where they can readily be seen by the operator, who, touching key after key, causes the letters to drop through corresponding grooves into the tubes ready to receive them, and the tubes as they are filled are transferred to the composing machine. The composer of Neill & Co., Printers, Edinburgh, has also obtained considerable favour, and is in principle similar to those already noticed.

In no department of printing have there been more efforts made in regard to improvement in speed than in the press-work. Within the last twenty years, indeed, this has been so rapid that it would be almost impossible to enumerate the various printing-machines placed in the market. Till the beginning of the present century that in use was but a common screw-press, hardly any improvement having taken place since the early days of block-printing. The type being placed on the bed of the press, it was rolled in under the *plattens*, which, on the screw being turned by the bar, was brought down on the type and the paper was printed. In the beginning of the 17th c., Jansen Blaew added a contrivance for releasing the impression when the bar was let go, giving it somewhat of a spring. In 1800, Earl Stanhope constructed a press of iron, and brought the impression to bear on the types by a system of levers which gave the use of a platten of double the former size, thus printing a much larger sheet, and obviating what was necessary in the old wooden press, a double pull before the whole sheet was printed. All subsequent presses more or less copied that of Stanhope, till 1817, when Clymer of Philadelphia invented the *Columbian*, which still holds the primary place among hand-worked presses, although the *Albion* of Mr. Cope (1824) is preferred by some for small-sized sheets. These various presses were soon followed by many others, among which may be named the *Napier*, *Imperial*, and *Britannia*. In 1790, some ten years before Stanhope's invention, Mr. William Nicholson took out patents for improvements in printing, and his specifications comprised almost every principle which has since been so successfully adopted in the making of printing-machines—proposing the use of a travelling type-bed, impression cylinders, and even spoke of printing from a web of paper by a cylinder surrounded with type acted upon by another covered with soft leather. Nicholson also invented the roller for applying the ink to the types instead of the hand-balls formerly used, and showed how 'grippers' could be used for holding the sheet to be printed, but he himself does not seem to have carried out any of his proposed improvements.

The first sheet ever printed by a machine, was one in a volume of the *Annual Register* for 1810, this machine being the inven-

tion of Koenig, a Saxon printer, who came to London in 1806, having in his own country received no encouragement in his belief that a press could be worked by mechanism. His partial success in England induced him to proceed further, and Koenig made a press which had a travelling type-bed passing under a series of ink-rollers, and an impression-cylinder which made a half-revolution when the type-bed was brought below it, standing at rest while the sheet was fed in. This attracted the attention of Mr. Walter, the proprietor of the *Times*, who commissioned Koenig to make a two-feeder machine for him, which he was ultimately successful in doing. It was first used with steam-power on November 28, 1814, attaining a speed of 1100 impressions per hour, and Koenig added yet further improvements which brought this number up to 2000. This machine was greatly simplified and improved by Messrs. Cowper and Applegath in 1818, and the same parties in 1824 produced a 'perfecting' cylinder-machine for book-work, in which both sides of the paper were printed in one revolution—that is to say, the pages on one side were printed exactly, 'registered,' on the back of the pages on the other side, and this was effected by the introduction of two drums between the impression-cylinders. The sheet being carried by a series of endless tapes over the first cylinder, was brought round to meet the face of the type on the travelling-bed as it passed from under the ink-rollers to the impression-cylinder, when it was taken up to the first drum and reversed: being then caught by the second drum, it was next passed round the second cylinder in exact time to meet the travelling type-bed from the other end of the machine. This machine was the prototype of those in common use in most book-printing offices at the present day. Mr. David Napier about the same time produced his machine, in which there was a rising and falling cylinder, and this invention was held in high repute by printers for many years. At first he had only a single cylinder; another was afterwards added, and this has lately developed through improvements by French makers into what is now known as the 'Anglo-French.' The best machine on the cylinder principle at the present date (1878) is that of M. Marinoni of Paris, and it is now rapidly superseding all others in the production of book-work of the finest kind. Koenig's first attempt was on the platten or flat-pressure principle in 1810, but it was not until 1829 that machines of this kind attained anything like success, when they were introduced by Messrs. Spottiswoode and Brown; for the finer kinds of book-work they are even yet preferred. Flat-pressure machines of many kinds are numerous now, while there are others in use which are a combination of both the platten and cylinder principle.

With newspaper machines, however, the rapidity of improvement has been something marvellous. Messrs. Cowper and Applegath in 1827 supplanted Koenig's machine in the *Times* with one having four impression-cylinders, which produced 6000 an hour, and this remained in use till 1848, when Applegath invented another, which had the type affixed to a rotary cylinder revolving on a vertical axis surrounded by eight impression-cylinders, and capable of producing 12,000 per hour. This vertical principle was discarded by Mr. Hoe of Philadelphia, who devised a machine in which the cylinders were placed horizontally, and which being more compact was driven at a higher speed. In Hoe's machine the types, and latterly stereotype plates (see STEREOTYPE), formed a segment of a large cylinder with a rotary motion, the sheets getting the impression between it and a series of smaller cylinders placed at equal distances round the main cylinder. Near each of the small ones a man was stationed with a pile of paper heaped up on a board before him, and a sheet was pushed in between the small and large cylinders at each revolution, the type-cylinder receiving its ink from rollers placed at certain intervals between the impression-cylinders. This machine had

also an ingenious contrivance attached, which dispensed with the manual labour of taking off the printed sheets, through the agency of 'fliers,' which laid hold of the papers and placed them on the delivery table. It could also be adapted so as to be fed with from two to ten sheets at one revolution, by enlarging the type-cylinder, and increasing the number of impression-cylinders, the latter turning out 20,000 an hour. Much of the ingenuity-exercised both in the Applegath and Hoe machines was directed to the 'chase,' which had to hold securely upon the curved face of the cylinder the mass of movable type required to form a page. The complicated contrivance by which this was effected was entirely superseded by the use of stereotype casts of the whole page in one piece.

All these newspaper machines hitherto noticed only printed on one side at a time, the second side being done subsequently on one or another machine, and it remained for M. Marinoni to invent one to print both sides at once. This 'perfecting' machine could also be adapted for several feeders, and produced 10,000 perfect newspapers per hour. The difficulties attending the feeding-in of so many sheets was always a drawback, and the idea of one that would mechanically feed itself from a roll of paper miles in length, which should print both sides at once, and deliver the printed papers folded or unfolded, long occupied the attention of printing engineers. At last three of these web-machines were produced in rapid succession. The first was an American one, the 'Bullock,' which has never attained any great success in this country. The real difficulties in the way were at length overcome by Mr. Macdonald, the printing manager of the *Times*, by whom and Mr. Walter the 'Walter Press' was first brought into operation in 1868, after several years of fruitless endeavours. In this reel or web of tightly-rolled paper, nearly 4 miles in length, and weighing about six hundredweight, is placed at one end of the machine. The paper is led from the reel (a) into a series of small cylinders (b), where it is damped, a process required with all paper that is to be printed, to enable it to take on the ink properly. It is then carried between the first and second (c) of four cylinders placed one over the other, where the first impression is received from the top cylinder, on which are fixed stereotype casts from the pages of one side of the newspaper. The paper then passes between the second and third (d), and resumes its forward direction in passing through the third and fourth cylinders (e), from the latter receiving the impression from the stereotype plates of the other side. It continues its course straight onwards till it reaches two other cylinders exactly in the centre of the machine (f), where by ingenious mechanism it is cut into sheets, each of which forms a single newspaper. At i is the ink supply, from which, by a number of rollers, the

ink is carried to the type-cylinders. Adjoining the cutter f is a self-acting index which counts the sheets as they are separated. The single sheets are now carried by tapes upward till they reach the apex of the triangle at the left side (g), whence they descend perpendicularly, and are thrown alternately backwards and forwards on to the boards, at which are seated the two boys,

Sectional Diagram of Walter Press.

who, with the exception of one man who starts the machine and looks after the rolls of paper, are all the attendants the machine requires; and even these boys may be dispensed with, as a folding apparatus can be fitted in where they are shown to be seated. 12,000 copies are printed in an hour at the lowest average, and the paper travels at the rate of about 1000 feet each minute. Other machines are now in operation very similar in principle to the 'Walter,' among these being the 'Prestonian,' the 'Donnison,' and the 'Victory,' the latter differing very little from the *Times* invention—mostly perhaps in this, that while the web paper in the 'Walter' is damped as it passes through two cylinders on first entering the machine, in the 'Victory' it is

carried over two water-troughs, spray from which, by a peculiar action, damps the paper, which is then partially dried upon hot rollers, after which it reaches the impression cylinders. To these machines there is generally a folding apparatus attached, which by a series of knives and grippers folds the papers ready for circulation. M. Marinoni, about two years ago, also adapted his machine, already noticed, to the web principle, and it is now also very much like the 'Walter' in its action, both in the printing and the cutting of the paper, as well as in the alternate delivery, the latter process always a special difficulty with fast-printing machines, where sheet succeeds sheet with great rapidity at intervals of only three or four inches at most. See *Horne's Introduction to the Study of Bibliography* (Lond. 1814); *Johnson's Typographia, or Printer's Instructor* (Lond. 1824); *Hänsard's Typographia* (Lond. 1825); *Timperley's Dictionary of Printers and Printing* (Lond. 1839); *Beckmann's History of Inventions, &c.* (Lond. 1846); *W. Blades' Biography and Typography of William Caxton* (Lond. 1877); but the best general treatise on the early history of the origin of printing which has yet appeared in English, or perhaps in any language, is that of Theo. L. De Vinne, *The Invention of Printing* (New York, 1876).

Printing of Music is of various kinds, the most common being (a) by plates composed of pewter or soft metal, on which the notes and characters are stamped with punches, and (b) by an ordinary press, the music and common type being printed together. The latter system is much used by publishers of cheap music. Movable music types are believed to have been invented about 1503 by Ottaviano Petrucci, of Venice, who obtained a patent for their use from Leo X. in 1513. The method of tying a number of quavers and semiquavers together by a common stroke was originated by John Playford of London in 1660. At the beginning of the 18th c., engraving music came into fashion. John Weisl, London (1710), was the first printer who substituted pewter for copper plates.

Prinzenraub ('The Stealing of the Princes') is the name specially given to the notable exploit of Kunz von Kaufungen, who, with the help of certain accomplices, seized and carried off in the night of the 7th July 1455, from the castle of Altenburg (q. v.), Ernst and Albrecht, the two sons of the Elector Friedrich of Saxony, and the respective founders of the Ernestine and Albertine branches of that House. Kunz was instigated to the deed by a desire for private revenge, he also he was obliged to deliver up certain possessions, given to him at one time as compensation for losses in the *Bruhlenskrieg* ('War of the Brothers'). On the way to Bohemia he was seized, near Gera, by a collier named Schmidt (afterwards Von Tuller), handed over to justice, and beheaded at Freiberg, 14th July 1455. See Schreier's *Geschichte des P.* (Leips. 1804); Gersdorf's *Einige Aelterstücke zur Geschichte des P.* (Altenb. 1855); and, in English, Carlyle's singularly graphic and powerful narrative of the incident in his *Miscellaneous Essays*.

Pri'or. See MONASTERY.

Pri'or, Matthew, born July 21, 1664, either at Wimborne or in London, received his education at Westminster School under Dr. Busby, and in 1682 was sent at the cost of the Earl of Dorset to St. John's College, Cambridge, where he graduated B.A. (1686), and was elected to a fellowship (1688). His patron brought him under the notice of William III., who employed him as secretary to various embassies, and successively created him a Gentleman of the Royal Bedchamber, Under-Secretary of State, and one of the Commissioners of Trade. In 1701 he was returned to Parliament by East Grinstead as a Whig, but ratted on Anne's accession, and in 1711 was despatched to Paris by the Tory Government to negotiate a peace. He revisited Paris in the following year as Bolingbroke's secretary, and remained behind him as vice-ambassador (1713), his conduct in this capacity leading, on the fall of the Tories, to his impeachment and two years' imprisonment (1715-17). On his release, P. had nothing but his fellowship to support him, till the publication of his poems by subscription, and Harley's generosity, brought him £8000, and he died, well-to-do and disreputable, at Wimpole, Lord Oxford's Cambridgeshire seat, September 18, 1721. It is as a poet that P. is chiefly remembered, but his poetry is almost utterly forgotten. It includes *The Town and the Country Mouse* (1687), written in conjunction with Montague, and meant

for a satire on Dryden's *Hind and Panther*; the *Carmen Seculare* (1690), full of bombastic praises of the 'Protestant Hero'; *Alma, or the Progress of the Soul*, a metaphysical Hudibras, without its wit; *Henry and Emma*, a feeble echo of *The Nut-brown Maid*; *Solomon*, moral and lugubrious; the highly-spiced but diverting *Tales*; and some neatly-turned *Epigrams*. The latest, and probably the last, edition of P.'s complete works is that by Mitford (2 vols. Lond. 1835), to which a memoir is prefixed.

Priscia'nus Cæsariensis, one of the most famous of the Latin grammarians, was born or educated at Cæsarea, and probably was contemporary with Cassiodorus (468-562 A.D.). His teacher was Theoctistus, and he himself taught grammar at Constantinople, receiving a salary from the government, a fact which goes to prove that he was a Christian. P.'s great work, commonly called the *Commentariorum Grammaticorum Libri XVIII.*, and addressed to his friend and patron, the consul Julianus, treats in the first 16 books of the eight parts of speech of the ancient grammarians, of letters, syllables, &c., and in the last two of syntax; the latter, in one MS., are placed as a separate treatise with the title *De Constructione*. This work, in which P. is most indebted to Apollonius Dyscolus, is learned, sensible, and of wide scope. It is specially interesting for its parallel between the Latin and Greek languages, which contains many quotations from writers whose works have otherwise utterly perished. The epitome by Rabanus Maurus, a German bishop of the 9th c., was extensively circulated. P. wrote ten other works, of which the most important are his *De Accentibus*, *De Duodecim Versibus Aeneidos Principalibus*, *De Declinatione Nominum*, *De Terenti Metris*, *De Sideribus*, and *De Laude Imperatoris Anastasii*. The best edition of P. is by Krehl (2 vols. Leips. 1819-20). See Bahr, *Geschichte der Römischen Literatur*.

Priscillianists were a Gnostic sect which appeared in Spain in the 4th c., and the first heretics who were persecuted. Their founder was Priscillian, who is said to have been influenced by one Marcus, a native of Memphis, but who began at anyrate to teach his heresy about 379. The bishops Idacius and Ithacius procured the condemnation of his doctrine at the Council of Cæsar-Augustus (380), and subsequently prevailed on the usurper Maximus to put him to death at Trier, 385. The sect continued to exist till the 6th c.

Prism, in solid geometry, is a figure bounded by planes which intersect in parallel lines, or, in other words, which are all perpendicular to a given plane. Consequently, the sections of a P. by any series of parallel planes are similar and equal; and the volume of any portion intercepted between two parallel sections is equal to the area of either section multiplied by the distance between the intersecting planes. A cylinder may be regarded as the limit of a P. whose sides increase in number and diminish in size indefinitely; and a P. may be regarded as a pyramid whose apex is removed to an infinite distance. It is evident that the minimum number of sides—i.e., the bounding faces exclusive of the ends—which a P. can have is three. In this form, it constitutes a most valuable instrument of research in physical optics. See REFRACTION and SPECTRUM ANALYSIS.

Prisoners of War. By the usage of modern civilised nations, officers made P. of W. are liberated on *parole*; that is, on giving their word of honour not to act against their captors during the existing war. Till that end, common soldiers taken prisoners are either retained in the country of their enemy, or exchanged. Non-combatants in the power of their enemy are not usually made prisoners, but they may fairly be required to contribute money and provisions to the enemy's maintenance. See ARMIES.

Prisons in Great Britain belong to the Crown. In every county there must be at least one common prison and one house of correction. The houses of correction are for the custody of vagrants, and of those summarily convicted by magistrates, or at quarter sessions. They are under the keeping of justices of the peace. Felons are imprisoned in the common gaol, of which the sheriff has the custody. The Queen's Bench division may commit any one to any prison in England; and the person committed by it cannot be removed or admitted to bail by any other court. 28 and 29 Vict. c. 126 consolidates and amends the law regarding the maintenance, government,

discipline, enlargement, and rebuilding of P. In Scotland, P. are under the management of the Department of P. and Judicial Statistics, established under the P. (Scotland) Administration Act, 1860, and the Judicial Statistics (Scotland) Act, 1869. The general prison for Scotland is at Perth, where convicts, prisoners under sentence of nine months and upwards, and criminal lunatics are confined. Several of the minor P. in Scotland were abolished in May 1878. An international congress on the subject of P. was held in Sweden in 1878. See JUVENILE OFFENDERS, REFORMATORY, CONVICT.

Pris'ren (*Peserim*), a town in a vilayet of the same name, in Albania, Turkey, at the N. base of the Shar Dag, on the small Bistritza, an affluent of the Drin, 30 miles S. by W. of Pristina, and 80 E. of Scutari. It is one of the richest industrial towns of Turkey, and has a citadel, 15 mosques (one with three cupolas), 1600 bazaars, and numerous caravanserais. The trade is chiefly in flints, pottery, glass, steel wares, and saddlery. In the vicinity is much swampy pasture, with poor villages and small vineyards. Pop. 35,000, of whom four-fifths are orthodox Greek Servians.

Pristina, a town of Turkey, vilayet of Prisren, lies in an amphitheatre of hills, 30 miles N.N.E. of Prisren. The chief town of Old Serbia, it has twelve mosques, several of which are imposing structures. Pop. 11,000.

Private, a common soldier in the cavalry and infantry regiments of the British army. His daily pay varies from 1s. in the infantry to 2s. 4d. in the Life Guards.

Privateer, a ship of war fitted out by a private individual in a belligerent state, and empowered by letters of marque from the government to make war upon the enemy's shipping, security being frequently taken for the due observance of the rights of neutrals and the law of nations. Such vessels were not considered pirates, and were often used as auxiliaries to the combatant naval forces of a country, till the Treaty of Paris (1856) abolished their use among European nations. During the American Civil War, the privateers commissioned by the Confederate States made great havoc among the trading vessels belonging to Federal owners.

Privet (*Ligustrum*), a genus of *Oleacea*, consisting of about ten species of shrubs, or rarely trees, distributed over a wide area in Europe and several parts of Asia, chiefly in the colder or temperate regions. The Common P. (*P. vulgare*) is a native of thickets in England, and is a generally familiar shrub in consequence of its frequent use to form garden hedges, which stand clipping without injury. Though of small size, its hard white wood is used by turners. The globose purple-black berries yield a rose dye, as also a bland oil employed in Germany for cooking purposes. Various Asian species of P. have been introduced into cultivation, being valued for their evergreen or sub-evergreen leaves and their profusion of handsome spikes of more or less fragrant flowers. The Shining-leaved P. (*L. lucidum*) was brought to England from China in 1794; *P. Nepalense* from Nepal in 1823; Japan P. (*L. japonicum*) in 1846; and a dwarf species, with dark, glossy, leathery leaves (*L. coriaceum*), also from Japan, in 1864. The foliage of these is often prettily variegated. *L. robustum* grows in India to a height of 40 feet, and its bark is used to put into toddy to cause immediate fermentation.

Privilege (Lat. *privus* and *lex*) originally signified a law passed against, afterwards one in favour of, an individual. In the latter acceptance, privileges may be positive, as patents and monopolies; or negative, granting exemption from ordinary jurisdiction, e.g., Benefit of Clergy (q. v.), and the feudal immunity of nobles from taxation. They are said to be personal when granted to a special individual, and real if attached to an office, as in the case of freedom of arrest enjoyed by members of Parliament, counsel, witnesses, &c. P. also attaches to place. No civil arrests can be made in the royal presence; nor within the verge of the Palace of Westminster; nor within the precincts of Holyrood Palace. In republics, real privileges can hardly be said to exist, and in other states they are continually decreasing in number, the division of the community into privileged and non-privileged classes no longer existing in any European country.

Privileged Debts are in Scotch law those which are preferable on the funds of a deceased person, and which an executor

may pay, without decree. They are deathbed and funeral expenses, according to the rank and fortune of deceased; mourning for widow and children; and a year's rent of the house, with servants' wages since last term.

Privileged Deeds are deeds held legal without the general statutory execution. The most important classes are Holograph (q. v.) deeds, mercantile letters, and bills and promissory notes.

Privy Council, a body of natural-born British subjects, appointed on the nomination of the sovereign as his advisers in state affairs. The council is supposed originally to have been a small permanent committee of the Great Council, and was composed, when summoned by Richard II., of the prelates, nobles, bannerets, &c. of the kingdom. It had very extensive powers during the reigns of the Plantagenets. Though the Crown had the prerogative of appointing its members, the parliament exercised considerable influence in their selection. The P. C. for a long period of time was composed of twelve members who sat continually and exercised great administrative, political, and judicial functions. The number gradually increased till in the reign of Charles I. that sovereign attempted to limit it to thirty, consisting of the great officers of state, the archbishops, and about fifteen others. The council has subsequently had an almost unlimited membership, and many of its duties have accordingly been assigned to committees of the great body. The 'Star Chamber' and 'Court of Requests' are such committees which have made themselves historical. The P. C.'s tendency to exercise jurisdiction in questions affecting the rights and liberties of private individuals was checked by 16 Charles I. c. 10, which declared such acts 'intermeddling' and 'illegal,' but subsequent to this statute the council was empowered to act in matters affecting the property of individuals arising out of the jurisdiction of the courts of the kingdom. A final separation of the P. C. from strictly political duties was made in the reign of William III., these being intrusted to the Cabinet, which is really a committee of the P. C. without recognised legal powers, consisting of the leading members of the existing administration. Among the various committees of the P. C. at present existing are the Board of Trade (q. v.), the Committee on Education (see below), and the Judicial Committee. The *Judicial Committee* was formed by Acts 3 & 4 William IV. c. 41, and had its powers confirmed and extended by 6 & 7 Vict. c. 38. It was entrusted with appeals from the Ecclesiastical and Admiralty Courts, in dealing with which it had powers of enforcing its decrees as great as those of the Court of Chancery. It was also the Court of Appeal for all cases from the colonies. It consisted of a number of the great legal officers, and by Act 34 and 35 Vict. c. 91 (1871) four additional judges were appointed as paid members of the Judicial Committee, at salaries of £5000 each. By the Supreme Court of Judicature, Act 36 and 37 Vict. c. 66 (1873), appeals from the High Court of Admiralty were transferred to Her Majesty's Court of Appeal, but it has still control of appeals from the Vice-Admiralty and Prize Courts abroad, from the Courts of the Isle of Man, the Channel Islands, India, and the Colonies, and from the ecclesiastical courts of England. Its functions also include the licensing of the republication of books and the authorising of the prolongation of patents. It sits daily except on Mondays and the usual legal vacations. It consists now (1878) of the Lord President, the Lord Chancellor, the Lord Justices of the Court of Appeals, the Master of the Rolls, the Lord Chief Justices of the Queen's Bench and Common Pleas, the Lord Chief Baron of the Exchequer, the Judges of Probate and Admiralty Divisions of the High Court, all privy councillors who have held any of these offices, certain puisne judges, and the four paid judges. Such prelates as are members of the P. C. are on the committee in ecclesiastical appeal cases.

The duties of a privy councillor as defined by oath are to advise discreetly for the Queen's honour and the public good, to keep secret her counsel, to avoid corruption, to help and strengthen that which shall be resolved, to withstand attempts to the contrary, and to do all that a true councillor should do for his sovereign. By 9 Anne c. 15, an unlawful assault on the person of a privy councillor was felony, but this has been repealed by 9 Geo. IV. c. 31. He enjoys the title of Right Honourable, and ranks in precedence after a Knight of the Garter. The Lord President of the Council is the fourth great officer of State, and a member of the Cabinet, with a

salary of £2000 a year. The Council usually includes the members of the royal family, the English archbishops, the Lord Chancellor, the Bishop of London, the judges mentioned as belonging to the Judicial Committee, the Speaker of the House of Commons, the ambassadors, many ministers plenipotentiary and colonial governors, the Commander-in-Chief, Cabinet Ministers, the Vice-President of the Board of Trade, the President of the Poor-Law Board, and other officers, in addition to all who have held any of these offices. Meetings of Council are held every few weeks at the sovereign's residence, at which only those councillors attend who have been specially summoned, and the Queen's decisions are then called her 'Acts in Council,' including as they do all her important personal resolutions. The P. C. inquires into all offences against Government, and commits offenders for trial. The Queen in Council may issue proclamations binding on her subjects, if consonant to the laws of the land, and also 'Orders in Council' on mercantile and international affairs. The Council has the power of appointing Sheriffs in England and Wales, and the framing of laws for such of the colonies as have not representative assemblies. It exists during the life of the sovereign, and for six months longer, unless dissolved by his successor. It is assembled on the proclamation of the new sovereign, and its members are then re-sworn, when the sovereign subscribes the required oaths on his assumption of the crown. On 1st January 1878 there were 204 Privy Councillors, 10 of whom were princes and high dignitaries, 10 dukes, 7 marquises, 28 earls, 7 viscounts, 1 bishop, 16 titular lords, 32 barons, and 93 commoners.

Privy Council, Committee of, on Education. See PUBLIC SCHOOLS.

Privy Purse, Keeper of the, an officer in Her Majesty's household charged with the payment of her private expenses and 'charities.' The annual vote in the Civil List for the Private Purse amounts to £60,000.

Privy Seal, is the seal of state, by which documents of minor importance are authenticated. Those of high import require the Great Seal (q. v.). The keeper is called the Lord P. S. He has usually a seat in the Cabinet. There is a P. S. in Scotland, under which the sovereign transmits such rights as a subject transmits by assignation.

Prize-Fighting and sword-playing are illegal, and if either of the parties be killed, the act is a felony.

Prize in War. Regarding military prize-money, see BOOTY. On a ship being taken, it must be sent to a port belonging to the capturing power, whose law courts must decide whether or not the vessel is a lawful prize. In the United Kingdom, this jurisdiction belongs to the Court of Admiralty. Appraisements and sales are to be made by agents appointed by the commanders and other commissioned officers. A certified list of those entitled to share in the prize is to be transmitted to Chelsea Hospital by the commanding officer making the capture. Agents are to remit the proceeds and amount of sales within one month after their date, under penalty of £1 per cent. per month. The net produce of the sale of a captured ship, approved by the court, is divided into eight parts, three of which go as P.-money to the captain, or if he is under a flag officer, one to the flag officer and two to the captain, one to the superior officers, one to the junior commissioned and warrant officers, one to the petty officers and midshipmen, and two to the general ship's crew. Due notice of division of funds and other practical details is appointed to be made in the London *Gazette* and in two of the London morning papers. See CAPTURE.

Prizzi, a thriving town of Sicily, province of Palermo, near the river Caltabelbota, 30 miles S. by E. of Palermo, and 10 W. of Lercara, a station on the Girgenti railway. It has manufactures of iron, copper, cotton, &c., and a pop. (1874) of 8835.

Pro'a (Span. and Port. 'a prow,' Fr. *proue*, Lat. and Gr. *prora*), or **Prahu**, a narrow sail canoe used by the Malays and Ladrone Islanders. It is about 30 feet long by 3 broad, carries a lugsail of matting, and has both ends paddled, and of exactly similar form. The lee-side of the P. is straight and flat, and from the other, which is rounded, there projects several feet a framework, to which a canoe-shaped float is attached. The float prevents the vessel from oversetting, while the framework

supports a weight to counteract the pressure of the sail. The P. is a fast sailer, its peculiar construction enabling it to move easily between two places with a side wind.

Probabilis Cau'sa, a Scotch law term denoting that a party wishing to sue, or defend, *In Forma Pauperis* (q. v.), has reasonable legal ground to stand on. The counsel for the poor determine the question of P. C.

Probabilism is one of the three cardinal propositions of Jesuitical casuistry; the other two being Mental Reservation and Justification of the Means by the End. P. was the A. B. C. of Jesuit morality in the time of Pascal (*Provincials*, 1656), and remains so to the present day, the very same maxims which were riddled by Pascal being taught yet in every Roman Catholic seminary in which Jesuit influence prevails, i.e., in the great majority. It is the system which applies to the guidance of conscience, the *opinio probabilis*, which is defined in authorised works on moral theology as 'any judgment resting on some really grave motive, though with fear of the opposite; that is to say, any opinion for which a grave motive can be adduced may be acted upon, notwithstanding an inward impression that it is opposed to the truth. Explicit tests are further given for what constitutes a 'probable opinion.' For persons 'of learning and uprightness' an opinion is 'assuredly probable' for his own guidance if he be 'conscious of having thought it out diligently,' and persuaded himself to his own satisfaction of its correctness. For ordinary people any opinion is probable which they may find expressed, though it be but by a single author, if he be 'of exceptional superiority.' For a person unversed in letters any opinion is probable, if it be that of one whom 'he himself deems to be possessed of learning and insight.' See *Compendium Theologiæ Moralis*, auctore P. J. P. Gury (Romæ, 1872); Pascal's *Provincial Letters*; Cartwright's *Jesuits* (Lond. 1876, or *Quart. Rev.* Nos. 274, 275).

Probability is the branch of algebra which investigates mathematically the chance of occurrence of any one of a given number of related possible events, some one of which at least must occur. For instance, if a die with six equal faces is thrown, there is evidently as much chance of any one face turning up as of any other. Limiting our attention to any one particular face, say the *ace*, it is clear that of the six equally possible ways in which the event may happen, one only is favourable to this event, being the turning up of the ace, the five others are unfavourable. Hence the P. of the ace turning up is one-fifth the P. of its not turning up. But, since the ace must either turn up or not, the sum of these probabilities must equal certainty; and therefore, representing certainty by unity, it follows that the mathematical expression for the P. of the ace turning up is the

fraction $\frac{1}{6}$, since $\frac{1}{6} + \frac{5}{6} = \frac{6}{6} = 1$. More generally, the theorem is thus expressed. If an event may happen in *a* ways, and fail in *b* ways, any one of these being equally probable, the chance of its happening is $\frac{a}{a+b}$, and the chance of its failing $\frac{b}{a+b}$. Suppose a bag filled with 12 balls, 7 of which are white and 5 black. If two are drawn at once, find the P. that they shall both be white. The number of favourable events is the number

of combinations of 7 taken 2 together, or $\frac{7.6}{1.2}$; and the total number of possible events is similarly 12 taken 2 together, or $\frac{12.11}{1.2}$. Hence the required P. is $\frac{7.6}{12.11} = \frac{7}{22}$. Now the P. that

one white ball should be drawn is evidently $\frac{7}{12}$; and after the one is drawn the P. that a second should be drawn is $\frac{6}{11}$, since now there

are only 11 balls left, 6 of which are white. But $\frac{7}{12} \times \frac{6}{11} = \frac{7}{22}$, the P. that two white balls should be drawn. This would lead us to expect the next general theorem in probabilities, that, if the P. that one event (A) should happen is *p*, and the P. that the second (B) should happen *q*, then the P. that both should happen together is *p q*. This may be established by rigorous reasoning, but the following indirect proof may be regarded as sufficient. The P. that A should not happen is $1 - p$; and the P. that B should not happen is $1 - q$. Assuming the theorem

that the P. that A and B should happen together is pq , it follows of necessity that the P. that A should happen and B not is $p(1-q)$, that the P. that B should happen and A not is $(1-p)q$, and that the P. that neither should happen is $(1-p)(1-q)$. But since every possible event is contained in these four methods of combining, the sum of the probabilities should equal unity, or $pq + p(1-q) + (1-p)q + (1-p)(1-q) = 1$. This is true identically, and therefore we are assured of the truth of the theorem. Generally, if p, q, r , &c., are the probabilities that certain events should occur independently, the P. that all should occur at once is the product pqr Thus the P. that a half-

penny should turn up heads in 10 successive throws is $\frac{1}{2^{10}}$; and this is evidently the P. that all of ten coins thrown together should turn up heads. Hence the P. that one at least is tails is $1 - \frac{1}{2^{10}} = \frac{1023}{1024}$. Another important theorem which hardly

requires further proof is that if an event may happen in different independent ways, the P. of its happening at all is the sum of the probabilities of its happening in the different independent ways. For instance, in the former case of the 7 white balls and the 5 black balls, what is the P. that the two drawn shall be of one colour? This may happen in two ways, either by both being white or by both being black. The P. of

both being white is $\frac{7}{22}$; and the P. of both being black is $\frac{5}{33}$;

hence the P. of both being of the same colour, whether white or black, is $\frac{7}{22} + \frac{5}{33} = \frac{31}{66}$. Let p be the P. of an event happen-

ing once, and q the P. of its not happening, so that $p+q=1$; then p^n is the P. of its happening every time in n trials. The P. of its happening all but one assigned time is $p^{n-1}q$; hence the P. of its happening $(n-1)$ times out of n trials is $np^{n-1}q$, since its not happening may be in any of the n ways, for each of which the P. is $p^{n-1}q$. Similarly the P. of its happening $(n-2)$ times is $\frac{n(n-1)}{1.2} p^{n-2}q^2$, since its not happening may be in any of the

$\frac{n(n-1)}{1.2}$ ways (n things 2 together), for any assigned one of which the P. is $p^{n-2}q^2$. And generally, the P. of an event happening $(n-m)$ times exactly out of n trials is

$$\frac{n(n-1)(n-2) \dots (n-m+1)}{1.2.3 \dots m} p^{n-m} q^m.$$

Hence the P. of an event happening m times exactly out of n trials is given by the $(n-m+1)$ th term of the binomial expansion $(p+q)^n$, which is of course identically equal to unity. Thus the P. that an ace turn up three times out of six throws with a die is $\frac{6.5.4}{1.2.3} \cdot \frac{1}{6^3} = \frac{625}{11664}$. Further applications and

theorems will be found in any of our standard text-books on algebra. The whole theory has an intimate connection with all questions regarding annuities, insurances, &c. See also Todhunter's *History of the Mathematical Theory of Probabilities*.

Probate, Probate Court. P. is the showing and proving of a will before the proper authority. All powers formerly vested in the ecclesiastical courts regarding wills and letters of administration are now transferred to the P. C. If the evidence for the will is sufficient, it is deposited in court and registered, and letters of administration granted to the executors. When a person dies intestate, or without naming executors, the court will grant power of administration to the next of kin. See EXECUTOR.

Proboscidea, an order of *Mammalia*, represented by the elephants. Formerly the P. were regarded as merely a group of the heterogeneous division *Pachydermata*, but the characters of the elephants are so well marked that their separation to form a distinct order is perfectly justifiable. Only two living examples of elephants exist, but the order P. includes the extinct *Mammoth*, *Mastodon*, *Deinotherium*, &c. See ELEPHANT.

Proboscis Monkey. See NASALIS.

Probus, Marcus Aurelius, a Roman Emperor, was born at Sirmium, in Pannonia, about 232 A.D., and early attracted the notice of Valerian, by whom he was rapidly promoted to the rank of tribune. As such he signally defeated

the Sarmatians, at the same time saving the life of a near kinsman of the emperor's; and having served with distinction in Asia, Africa, and Germany, was appointed by Tacitus commander-in-chief of all the eastern provinces. On Tacitus' death in April 276, P. was raised to the imperial purple by the legions of the East, and their choice was ratified by the Senate when, three months afterwards, Florianus, the late Emperor's brother, was murdered at Tarsus by his own soldiers. To the Senate P. committed the civil administration of the empire, and himself achieved the deliverance of Gaul by the recovery of seventeen flourishing towns and the slaughter of 400,000 Franks, Burgundians, and other German invaders (277). He next carried his arms into the heart of Germany, built a wall extending from the Danube to the Rhine, and forced the vanquished tribes to furnish a contingent of 16,000 recruits, whom he distributed amongst the armies of the empire. P. also subdued the Blemmyes and Isaurians, crushed the revolt of Saturninus at Alexandria (279), and of Bonosus and Proculus in Gaul (280), and finally, returning to his capital, there celebrated a splendid triumph. Strangely enough, the hopes of this great conqueror all tended towards a Utopia where standing armies should be no longer a necessity—hopes whose utterance cost him his life by rousing the jealousy of the soldiery. He was superintending some troops employed in the drainage of the Sirmian marsh, when they suddenly rose against him, dragged him from the tower in which he sought to escape their fury, and stabbed him with a thousand wounds, August 282. 'Just by name and just by nature, a conqueror both of tyrants and barbarians,' is the epitaph with which Vopiscus, our chief authority, closes his brief biography of P. See ch. xii. of Gibbon's *Decline and Fall*.

Process, in law, is a term comprehending all the writings, forms, and pleadings by which an action, civil or criminal, is brought under judicial cognisance. It includes all that takes place, from the first step down to the final decree in a civil action, and to the conviction or acquittal in a criminal prosecution.

Processional was a service-book containing rules for the arrangement of processions, which originated in the Western Church about the middle of the 5th c., though used in the East perhaps a century earlier, and formed a very prominent feature in the ritual of the Medieval Church.

Procession of the Holy Ghost is the term used to express the relation of the Third Person of the Trinity to the Divine Essence, being analogous to the term Eternal Generation, which is applied to the Second Person. See FILIOQUE.

Processions formed a prominent feature in the ancient festivals of Bacchus, Ceres, and other divinities, as also in the Jewish worship. They were introduced in the 4th c. A.D. into the Catholic Church, where their character is threefold—of supplication, as on the Rogation Days (i. v.); of atonement, on Good Friday; and of praise and thanksgiving, on all the higher feasts. In Protestant countries they are generally confined to the churches, but elsewhere they are often conducted through the streets, the procession at Munich on the feast of Corpus Christi being one of the most splendid on the Continent. At the service of Solemn Benediction, during the singing of the *Pange Lingua*, P. of the Blessed Sacrament are made round the church at Easter, Christmas, on the feasts of the Blessed Virgin Mary, &c. Minor P. are those of the Asperion, the Stations of the Cross, and at the opening and closing of service.

Procida, the *Prochyta* of the Romans, a small island about a mile from the W. horn of the Bay of Naples, and midway between the mainland and Ischia. It is composed of pumice-stone and lava, and consists of the only remaining sides of two contiguous craters, forming two semicircular bays. It is 3 miles long, varies much in width, and has a somewhat flat surface. Its inhabitants (13,800 in 1874) are engaged in fishing and in cultivating the vine and other fruits. The town, at the N.E. extremity, has a good harbour, a castle perched on a precipitous rock, and a memorial to twelve Procidians who were executed during the reaction of 1799, erected in 1863.

Proclamation, Royal. In former times it was held that a P. R. under the Great Seal had the force of an Act of Parliament, and it was so declared by statute 31 Hen. VIII. c. 8.

This was repealed in the following reign. The doctrine was, however, maintained by the Stewart kings in their disputes with their parliaments. It was finally abandoned by the royal assent to the Act 1 Will. and Mary, c. 2.

Proclus, the last of the Neoplatonists, was born at Constantinople, February 8, 412 A.D., passed his childhood at Xanthus, and coming whilst still a youth to Alexandria, learnt grammar from Orion and rhetoric and law from Leonas. With the latter he revisited the city of his birth, and on his return to Egypt abandoned the study of jurisprudence for that of mathematics and philosophy, in which his instructors were Hero and Olympiodorus. About 431 he removed to Athens, where Plutarchus and Syrianus initiated him in the Aristotelian and Platonic systems, and where by the age of twenty-eight he had published a commentary on Plato's *Timæus*, with other treatises. On Syrianus' death, P. succeeded to his chair, and lectured with profit to himself at least, till, by his open observance of pagan rites, incurring the suspicions of the Christian government, he was forced to retire for a year to Asia. This interval he employed in mastering the mysteries of the East, and for five years after his return to Athens he laboured at a compilation of the Chaldean oracles. Thenceforth P. lived more circumspectly, veiling his esoteric doctrines from the vulgar, though secretly practising a rigid asceticism, and holding in reverence every creed but one, the Christian. Worn out with fastings, he died April 17, 485, and was buried near Lycabettus. In his philosophy P. pushed Plotinus' mysticism to its logical absurdities, teaching that a hierarchy of ideas, with a ceaseless generation from the abstract to the concrete, presented the perfect pattern of a hierarchy of existence, where unity incessantly gave birth to individual phenomena. Plato's maxim, 'Know thyself,' he interpreted as meaning that self-knowledge is the only means towards knowledge of any kind, and must be obtained, neither from others nor by personal investigation, but by illumination from above, from Hermes the messenger of Zeus. Faith with him was paramount to science, enabling mankind to appreciate the good, that is, the one; and reason was faith's expositor. In his interpretation of the Orphic poems and Chaldean oracles, which he regarded as the revelation of heaven, he sought less to strike out novel conceptions of his own than to elaborate the doctrines of Aristotle, whom he termed 'the philosopher of the understanding,' and of Plato, 'the philosopher of reason,' at the same time allegorising the latter's every word and action. There is no complete edition of the twenty-two extant works of P., the fullest, by Cousin (6 vols. Par. 1820-27), containing his commentaries on Plato's *Parmenides* and *Alcibiades*, his *Decem Dubitationes circa Providentiam*, and *De Malorum Subsistentia*. Taylor's English translation (2 vols. 1820) gives his commentaries on the *Timæus*, *Alcibiades*, and *Theologia*, his treatise on the first book of Euclid, *Institutio Theologiae*, and five of his hymns. See Rutter, *Geschichte der Philosophie* (12 vols. Hamb. 1820-53); Brandis, *Geschichte der Entwicklung der Griechischen Philosophie* (2 vols. Berl. 1862-64); and Lewes, *History of Philosophy* (2 vols. Lond. 1867).

Procelia, a division of the order *Crocodylia*, including all the living members of the group, and named from the form of the bodies of the vertebrae or joints of the spine, these being hollow, or concave in front and convex behind. Extinct crocodiles had *amphialous* or fish-like vertebrae (i.e. hollow at either extremity) or *episthecalous* vertebrae—the opposite of the procelous.

Proconsul, a Roman officer, who, though not consul was invested with consular powers (*imperium et jurisdictio*) except in the city and its immediate vicinity. The first P. was Q. Publius Philo, whose *imperium* was prolonged in 327 B.C. in the second Samnite war to enable him to follow up his victories. At a later period it was usual for the consuls, on the expiry of their office in Rome, to be despatched to conduct a war in some of the provinces, or to carry on its government. A year was the legal period, but the Senate might extend it. Sometimes, as in the case of young P. Cornelius Scipio in the Spanish war, a man was made P. who had not been consul. This was very common towards the close of the Republic. Later still, parts of the dioceses established by Constantine were ruled by proconsuls.

Procop, the name of two celebrated Hussite (q. v.) leaders. After the death of Ziska in 1424, part of his followers, naming

themselves the 'Orphans,' chose as their leader **P. the Little**, while the main body of the Taborites (q. v.) followed **Andreas P. the Great**, or **The Shaven** (Czech, *holý*, 'bald'), so called from his having been a monk. They defeated the citizens of Prague in 1425; the Germans at Aussig on the 16th June 1426; in March of 1427 took Mies, and drove in flight from that city an army of 'Crusaders,' and in December occupied Kolin. From 1428 to 1430 they ravaged Moravia, Hungary, Silesia, Austria, Bavaria, Lusatia, Thuringia, and Franconia; even during the negotiations for peace at Eger in the spring of 1432, they led forays through Brandenburg as far as Berlin. Their struggle with the moderate Calixtines after the conclusion of the 'Compact of Prague' at Basel (30th November 1433), ended in the defeat and death of both leaders in the bloody battle of Lipan and Hrzih, near Böhmisch-Brod (30th May 1434).

Procopius, a Byzantine historian, was born at Cæsarea, in Palestine, about the beginning of the 6th c. B.C. Coming early to Constantinople, he became secretary to Belisarius (527), whom he attended on his campaign against the Vandals (534), and in the Gothic war (535-40) was placed at the head of the Byzantine navy and commissariat. After his return to Constantinople (541) the Emperor Justinian raised him to the rank of senator, with the title *illustris*, and in 562 created him prefect of the city. P. died about the year 565. He wrote the history of Justinian's wars, in eight books, with strict impartiality; next to the emperor's glorification described his splendid buildings in the *Ktismata*; and finally retracted all his praises in the *Anecdota*, a *chronique scandaleuse* of the Byzantine court, whose authorship, however, has been questioned. The best complete edition of his works is by Dindorf (3 vols. Bonn, 1833-38). See Dahn, *P. von Casarea* (Berl. 1865).

Procrustes (Gr. 'the stretcher,' from *prokruō*), the surname of the Attic robber Polypemon or Damastes, who forced all travellers that fell into his hands to lie down on a bed of torture, to suit whose length he lengthened their bodies by racking, or shortened them by cutting off a part of their legs, till himself subjected to the same treatment by Theseus. Hence 'the bed of P.' is a term figuratively denoting unfair extension or abbreviation.

Procter, Bryan Waller, better known as 'Barry Cornwall,' was born either in Wiltshire or London, November 21, 1787. He was educated at Harrow, where Byron was his contemporary, entered the office of a solicitor in Wiltshire, but returned to London in 1807, and devoted himself to literature, gradually becoming intimate with Hunt, Lamb, Hazlitt, Keats, &c. In 1831 he was called to the bar by the Society of Gray's Inn. He held for some time the post of Commissioner of Lunacy, but resigned it in 1861. Jeidan, editor of the *Literary Gazette*, says in his biography that P.'s first poems appeared in that periodical. He published *Dramatic Scenes and other Poems* in 1819. This volume was followed by *Murcian Colonna* (1820); *A Sicilian Story* (1820); *Mirandola*, a *Tragedy* (1821); *The Flood of Thessaly and other Poems* (1822); *English Songs and other Poems* (1832). His *English Songs and Smaller Poems* appeared in 1852. P. likewise edited Moxon's edition of Shakespeare (1839-43), and an edition of Ben Jonson (1838). He wrote a pleasant *Memoir of Charles Lamb* (1860); a *Life of Edmund Keats* (1835); *Effigies Poeticæ, or Portraits of British Poets* (1824); and *Essays and Tales in Prose* (1851). He died in London, October 4, 1874. P. belonged to the school of Keats and Hunt, and did much to revive a taste for the simple beauty of the earlier English poets. His lyrics were equalled among his contemporaries only by those of Moore; and, like Moore's, his style is sometimes defective in taste. See Bryan Waller P., *An Autobiographical Fragment, and Biographical Notes, with Personal Sketches of Contemporaries, Unpublished Lyrics, and Letters of Literary Friends* (Lond. 1877).—**Adelaide Anne P.**, daughter of the preceding, the 'golden-tressed Adelaide' of her father's poems, was born in London, October 30, 1825, and early developed a poetical taste like her father's. Her *Legends and Lyrics* appeared in 1858-61 (new ed. with preface by Charles Dickens, 1866), and besides contributing to the magazines, she wrote some of the pieces contained in the *Victoria Regia*. Miss P., who had become a Roman Catholic, died in London, February 2, 1864.

Proctor is the name given to the practitioners in the civil and ecclesiastical courts. The functions of a P. correspond with those of an attorney in the courts of common law. Proctors had privileges which were abolished by recent statute, compensation being given to them.

Proctors, at each of the universities of Oxford and Cambridge, are two masters of arts, nominated yearly by the colleges in rotation, and charged with the censorship of the morals of the undergraduates. They have the power of fining students whom they find smoking in the public streets, or walking them after dusk without their academic dress, dining in taverns, driving tandem, or otherwise infringing the university statutes. Their authority, as that of their deputies, the pro-proctors, extends over the townspeople, and they possess official votes in the election to several professorships and other offices. Proctor is also the title of the deputies returned by the parochial clergy to Convocation (q. v.).

Procurator-Fiscal is in Scotland a legal officer of the crown. He superintends precognitions (see **PRECOGNITION**), and it is at his instance that criminal proceedings may be instituted before sheriffs and inferior magistrates. They have the functions also of coroners in England. Though appointed by the sheriffs, they are accountable to the crown counsel, and in cases of difficulty it is their duty to communicate with the crown agent. The P.-F. may prosecute for the public interest, on the ground of a private complaint; but when he believes that the complaint is made rather in furtherance of private than of public interest he should decline to take the initiative. To obtain damage for prosecution against a P.-F., malice must be proved. Procurators-fiscal are now paid by salary. See in English law under **CRIMINAL**, **CRIMINAL PROCEDURE**, and **PROSECUTION**, **CRIMINAL**.

Pro'cyon. See **RACoon**.

Procyon, a star of the first magnitude in the constellation *Canis Minor*. It is readily found from its proximity to Orion, which it follows through the heavens. It forms with Sirius and Betelgeuse a nearly equilateral triangle.

Prodd, a light crossbow used in sporting, especially by ladies, during the 16th and 17th centuries. Queen Elizabeth is reported to have been very expert in shooting deer with it. In the reign of Charles I. the P. was sometimes combined with the pettonel.

Producta, a well-known genus of Brachiopodous shells, forming the type of the family *Productide*. In this group, which includes only fossil forms, the shell was free, or was attached to rocks directly, and without the intervention of a stalk. No 'carriage-spring apparatus' existed for the support of the arms. The genus P. itself first occurs in a fossil condition in the Devonian period, and ranges through the Carboniferous to the Permian rocks. It is thus exclusively Palæozoic in its distribution. *P. Cora* of the Carboniferous is a typical example. The shell is long, crosswise, and may have ear-like processes. The hinge-line is straight, and the ventral valve is convex. The shell surface is marked with prominent lines.

Professor, a title among the Romans borne by public teachers of grammar and rhetoric, at the mediæval universities was almost synonymous with *Doctor* and *Magister*. Gradually, however, as the taking of a degree ceased to entail the duty of instruction, there arose a regular body of lecturers in the various faculties, to whom the name Professors was distinctly applied. In the Scotch, Continental, and American universities the education of the students is almost wholly intrusted to the professors, their lectures being the only recognised channels of instruction; but in the English Universities of Cambridge and Oxford (q. v.) the professional functions have gradually been usurped by college and private tutors, and a student can at present obtain his degree without having attended a single P.'s lecture. The tendency, however, of recent legislation has been to increase the activity of the professoriate, and to establish new chairs of languages, science, &c. See **UNIVERSITIES**.

Profile (Fr. *profil*, Ital. *profilo*, from Lat. *filum*, 'a thread') denotes generally a view of the perpendicular section of a body. In architecture, it is the contour of the different parts of an elevation; in fortification, the vertical cross section of a work; in

painting, an outline drawing of the side of the face. See **SILHOUETTE**.

Prognosis is the term employed in medicine to indicate the opinion of the physician or surgeon regarding the probable termination of a disease. In forming a P. the physician takes into consideration the nature of the disease, and also numerous modifying circumstances, such as age, sex, mode of life, previous state of health, &c. Some diseases and injuries are necessarily fatal; and a tolerably accurate P. regarding the duration of life may be made; but many diseases terminate fatally through complication, and on account of unfavourable circumstances. In such cases the difficulties in the formation of a correct P. are greatly increased.

Progression, in mathematics, is the name given to certain algebraic series, whose succeeding terms are related in a particular manner to each other. Thus, in the arithmetical P., the difference between any two contiguous terms in a given series is constant for that series; in the geometrical P. their quotient is constant; in the harmonical P., the reciprocals of the terms form an arithmetical P.

Progression, in music, is a succession of notes in the same key, forming a melodious sequence. Harmonic P. is the movement of one chord to another. The P. is direct when the parts rise or fall together, contrary when they move in different directions, oblique when one part repeats the same note while the other varies.

Progress of Titles, in Scotch law, means a chain of title-deeds to heritable (real) estate sufficient to constitute a valid feudal title. In case of a sale, the seller is bound, unless there is a stipulation to the contrary, to give the purchaser a sufficient P. of T.; but as difference of opinion sometimes arises as to what *are* sufficient, an intending purchaser will do well to satisfy himself regarding titles before making an offer.

Prohibition, in English law, is a writ from a superior court of law to prohibit an inferior court from further procedure in a cause. In Scotch law the word denotes a clause in a deed of entail restricting the power of the heir of entail.

Projectiles, The Motion of, is a study of growing importance in modern warfare. Though ordinarily limited to the case of a projection in a more or less horizontal direction, the theory includes all cases of falling bodies. We shall consider those simpler cases first in which there is only vertical motion. When a mass is raised above the surface of the earth, experiment shows that if left to itself it will inevitably fall down in virtue of the attraction which exists between it and the earth. Though this attraction diminishes as the distance increases in accordance with Newton's law of gravitation, yet, for the comparatively small variations of distance which are considered in studying projectiles, the variation in the force of attraction is inconceivably small, and is fairly negligible in discussing the motion. We may therefore regard the force with which a body of given mass is pulled downwards towards the earth as constant for that body, and this force we conveniently call the *weight* of the body. Consequently the body suffers a constant acceleration; and the product of the mass into the acceleration is the measure of the weight. It was established by Galileo that every body suffered the same acceleration; and hence the weight of a body at any one place on the earth's surface is directly proportional to its mass. Subsequent experiments have shown, however, that the acceleration varies from place to place on the earth's surface, so that the weight of a body is a function of the latitude. Let g then represent the acceleration produced in one second upon a falling body under the action of its own weight. Then $W = Mg$, where W is the weight and M the mass. Suppose the body to fall from rest, then its velocity at the end of t seconds is gt ; and the space described, being the product of the *average* velocity and the time, is $s = \frac{1}{2}gt^2$. If the body has a velocity V to begin with, its velocity at time t becomes $v = V + gt$. The average velocity is $\frac{1}{2}(V + v) = V + \frac{1}{2}gt$; and hence the space described is $s = Vt + \frac{1}{2}gt^2$. If the body is projected *upwards* with velocity V , the acceleration acts against the motion so as to diminish it. In this case the velocity at time t is $v = V - gt$; and the space described is $s = Vt - \frac{1}{2}gt^2$. As time goes on, v diminishes uniformly until, when $V = gt$, it is zero. The space described is then $s = gt^2 - \frac{1}{2}gt^2 = \frac{1}{2}gt^2$; or, in words, any

body projected upwards with a given velocity ascends to that height from which, if it were allowed to fall, it would reach the earth with a velocity equal to the velocity of projection. Again, since $v - V = \pm g t$ and $\frac{1}{2}(v + V)t = s$, we have at once

$$\frac{1}{2}(v^2 - V^2)t = \pm g s t,$$

or $v^2 = V^2 + 2gs$, a formula expressing the space described in terms of the initial and final velocities. These equations afford the means of working any given problem on falling bodies as long as there is simply vertical motion. The problem is considerably more complicated when the velocity of the projectile has a horizontal component as well as a vertical. It may be generally expressed thus. What is the path of a body, projected in any direction, and under the influence of a constant force acting in one direction? In the case of a projectile, the force is its own weight and acts downwards. There is no horizontal force, and therefore no horizontal acceleration. Let

Diagram showing Trajectory of Projectiles.

AB represent the horizontal so that there is acceleration only perpendicular to AB. Let a body be projected from A in the direction AP, with a velocity V . Let Ap be the space described in time t if there were no acceleration, i.e., $Ap = Vt$. The body, however, under the action of a constant vertical force, will evidently be at P, where pP is perpendicular to AB, and is clearly the distance through which the body would fall from rest during the same interval of time t . Hence $pP = \frac{1}{2}gt^2$. But Ap is the tangent at the point A to the curve AP, and, combining the two last equations, $pP = \frac{1}{2} \frac{g}{V^2} Ap^2$, or

pP is proportional to the square of Ap —a property of the common parabola. Hence the path described by a projectile is in general a parabola, provided that there is no force acting but that due to gravitation. Practically this latter condition does not exist, since the air offers to the motion of the projectile a resistance which is a function of the velocity. For moderate velocities the resistance is approximately proportional to the square of the velocity; but for the high velocities obtainable by our modern ordnance, a much more complex relation holds, which can be expressed only by an empirical formula established by experiment. For details of experiments made at Woolwich, see Bashforth's *Motion of P.*

Projection of a given figure with reference to a given point is the section by any plane of the pyramid or cone formed by drawing right lines from every point in the figure to the given point as vertex. It thus appears that any one conic section may be regarded as the P. of another. The plane in which the cone is cut is called the plane of P.; and it is easily seen that a P. on a plane parallel to the original plane is a figure exactly similar to the original figure. Since the section of a plane with another plane is always a straight line, a right line will always be projected into a right line. Further, from the construction it is evident that to any point in the one figure there will correspond a point in the other. Further, the original figure is a P. of one of its own projections; and if it is possible in any way to reason from the known properties of the figure to corresponding properties of its projections, it is equally possible to deduce the properties of the figure from any particular P. It is in this that the real power of projections as an analytical method lies. Thus, from any known geometric property of a circle, we may pass by P. to a general theorem which holds for all conics. We thus reason from the simpler to the more general theorem; whereas, in ordinary algebraic analysis, the former is inferred as a particular case of the latter. It has been seen that to every point and line in one figure there corresponds a point and line in the other; but this corresponding point or line may in certain cases become imaginary. As a familiar instance we may mention the hyperbola, whose points of intersection with certain right lines through the centre are wholly imaginary, and yet they correspond to real points on an elliptic or circular P. Now the method of projections recognises these, and by the *principle of continuity*, as it is termed, asserts the properties of a figure in

which certain points and lines are real to be true even when some of these become imaginary. If the vertex of the cone of P. is removed to an infinite distance, the projections of the figure are sections of a cylinder; and the section made by a plane perpendicular to the axis of the cylinder is called the *orthogonal P.* of the figure. It may also be defined as the locus of the points where perpendiculars upon a given plane from every point of a given figure meet that plane. Any ellipse may be orthogonally projected into a circle; and the orthogonal P. of a sphere is always a circle.

Prolapsus Ani consists in an inversion of the lower part of the rectum, the protrusion being in the form of a ring of red, tumid membrane. In slight cases, the protrusion consists of the mucous membrane only, but in more formidable cases the whole bowel sometimes protrudes for several inches. The causes of P. A. are constitutional and local. In cachectic children any intestinal irritation may cause P. A., and even among healthy persons it may depend on any cause of straining, as stone, stricture, or enlarged prostate. In the treatment of P. A. the first thing is to ascertain and remove the cause, and the P., if moderate, will soon disappear with a little attention. The protruded parts should be carefully returned with a little pressure; and, should any difficulty be experienced, the operation will be facilitated by smearing the parts with a little oil or grease. The recumbent position should be maintained for a few hours, and the parts supported by a T-bandage. When the protrusion is very large the mucous membrane should be pencilled over with nitrate of silver, or smeared with nitric acid. In very severe cases an operation similar to that for piles must be performed, portions of the inverted gut being tied at opposite parts of the circumference of the bowel, so that the intestine may be kept in position by the resulting cicatization.

Prolapsus Uteri, Procidentia, or Decensus Uteri, consists essentially in a depression of the womb below the natural level in the pelvis, and is popularly known as 'falling down of the womb,' or 'bearing down.' P. U. occurs most frequently in females beyond the middle age who have borne children; but it happens frequently to women after their first confinement, and disappears after the second altogether, owing to the greater ease displayed during convalescence. Cases, however, are not uncommon among those who have never borne children, even in maids, and in children of tender years. The prolapsus is termed *imperfect* when there is no external protrusion, and *perfect* when the womb is protruded externally. The immediate causes are—1. Relaxation of the broad and round ligaments above; 2. a want of due tone in the vagina below. By the first the uterus is permitted to fall; and, by the second, the uterus is allowed to be received into the cavity. The relaxed condition of the vagina is probably the chief cause, and the descent will be accelerated by any condition causing increase in the weight of the womb, such as congestion, hypertrophy, fibrous growths, &c. The symptoms of P. U. are principally mechanical, arising from pressure upon other organs, from their being involved in the displacement, or from the sympathies of other organs with the uterus. The earliest symptoms are a sensation of fulness in the pelvis, of weight and bearing down, dragging from the loins and umbilicus, and pain in the back extending to the groins. These symptoms are aggravated by standing or walking, and are most severe in the evening.

Treatment.—The preventive treatment of P. U. consists in causing the patient to maintain a recumbent position when suffering from any form of uterine disease in which there is enlargement of the organ, and while under treatment for the same. A relaxed condition of the vagina may be treated by the application of cold, and the injection of astringents; or the insertion of astringent suppositories; but such agents should be applied with caution, as they would do harm when there is any degree of acute or chronic inflammation of the vagina or uterus. The improvement of the general health will often have a remarkable influence upon the P. U. in the first stage. When the prolapsus is complete, the part should be reduced and retained in its proper position by a pessary. The most important part of the treatment, in cases of extreme P. U., is rest in the horizontal position with the uterus completely reduced. If this can be insisted on for a sufficient length of time, the patient will be restored to fair comfort and a certain amount of activity by the use of the pessary.

Prolétaires has been commonly adopted in European literature from the French as a term of designation for the poorest labouring class. It is not so low as the 'residuum,' rendered famous by Mr. Bright in 1866, but it still retains much of the early Roman meaning—'a citizen of the lowest class, who, from his poverty, was useful to the state only by producing children' (*proles*).

Prome, the chief town of the district of the same name in British Burmah, on the left bank of the Irawaddy, 175 miles N. of Rangoon; pop. (1872) 25,631. It was captured in the first Burmese war of 1825, and permanently annexed after the second war in 1852. P. has considerable commercial importance, as the highest station in British territory of the steamboat traffic on the Irawaddy, and the frontier town towards Independent Burmah. In 1877 a state railway was opened from Rangoon to P.—The district of P., which lies on the E. bank of the river, has an area of 2887 sq. miles, and a pop. (1872) of 274,872.

Prometheus, in Greek mythology, was son of the Titan Iapetus by Clymene, and brother of Atlas, Menætiæus, and Epimetheus. According to Hesiod, the gods and men were disputing at Mecone regarding the 'parts of animals which should be offered in sacrifice. P. divided a bull into two parts, the flesh and entrails in the skin for one, the bones covered with fat for the other. Jupiter, being asked to choose a portion for sacrifice, selected the latter, and, enraged at the success of the artifice, withheld fire from mortals. P. then stole fire from heaven in a tube. For this theft P. was fastened to a pillar, an eagle every day feeding upon his liver, which every night grew again. At length Hercules killed the eagle, and freed the prisoner. This myth underwent many changes in the hands of the poets. In the *Prometheus Vincit*, P. is represented as the great benefactor of men, the teacher of all the arts, as well as the fire-bringer. But in this he has disobeyed Zeus, and hence his terrible punishment on Caucasus, which he sublimely, but from the Greek point of view rebelliously endures, refusing firmly to divulge the secret on which Zeus's safety depends. The *Prometheus Unbound* of Shelley deals with the phase of the myth supposed to have formed the subject of the last play of the *Æschylean* trilogy, but in a different spirit from that of *Æschylus*. In the latter, Zeus and his victim are reconciled; but Shelley 'was averse from a catastrophe so feeble as that of reconciling the champion with the oppressor of mankind,' and he sets before us a Zeus-defying hero who survives the fall of the deity dragged into 'the abyss,' by the awful shape of Demogorgon, and who is liberated by Hermes from his rocky prison on Caucasus amidst the rejoicings of the Powers of Earth. See the learned disquisitions of Welcker in his *Æschylische Trilogie Prometheus* (Darmstadt, 1824), and Professor Blackie's essay in the *Home Hellenica*.

Prom'issory Note. See BILL.

Promotion in the Army and Navy. In the British army, since the abolition of the Purchase System (q. v.) in 1871, P. has been by 'seniority tempered by selection.' First commissions are given (1) to successful candidates at the Civil Service Commissioners' open examinations, whose ages must range from seventeen to twenty; (2) to university students or lieutenants in the militia, aged seventeen to twenty-two, who have passed certain examinations; (3) to non-commissioned officers aged seventeen to thirty specially recommended; and (4) to Queen's and Indian cadets and pages of honour. By far the greatest number enter the army from the first class. On receiving commissions as sub-lieutenants they are sent to the Military College at Sandhurst (or to their regiments if in India), and at the end of a course of military instruction and the passing of an examination are eligible to be promoted as lieutenants. Before P. to a captaincy at least two years' service as lieutenant is required, the usual period being from eight to eleven years. Regimental vacancies, as a rule, are filled up by P. from the regiment if they occur by death, the step being given to the senior officer of the next grade, and according to the discretion of the Secretary of State for War and Commander-in-Chief if they occur otherwise. To qualify for a captaincy the passing of an examination in regimental duties, drill, military law, tactics, fortification, &c., is required, and in the case of a majority an

examination in subjects connected with the command of a regiment, or of a small mixed force in the field. The appointment of major is for five years, but is renewable. A brevet-majority is obtained by seniority in the army, or granted for distinguished services. Regimental P. ceases with the rank of lieutenant-colonel. A lieutenant-colonel becomes colonel by brevet after holding the command of a regiment, or a similar staff appointment, for five years, or after eight years under certain conditions, or on appointment as aide-de-camp to the Queen. P. of colonels to the rank of general officers is by seniority regulated by fixed establishment, except in cases of P. for distinguished services. Field-m Marshals are appointed at the will of the sovereign without reference to seniority. In the artillery and engineers first appointments are granted through the Royal Military Academy at Woolwich, entrance to which is obtained by open competitive examinations. After a three years' professional course commissions are granted according to standing on the examination lists. The engineers go through a further course of instruction at Chatham. P. then follows purely by seniority. Brevet promotions are on the same footing as in the other branches of the service. There is a separate establishment of general officers for the artillery and engineers.

The P. of non-commissioned officers in the army and of petty officers in the navy is by selection. For officers in the navy the rule is P. up to the rank of captaincy by selection and beyond it by seniority.

The retirement of officers in the army is now regulated by the army warrant of 1877 which is calculated to ensure a more rapid flow of P.

In countries where military service is compulsory, and which lack the large middle class which characterises Great Britain, it is a natural consequence that P. from the ranks should be more extensive. In the *French* army many officers still rise from the ranks, though not to the same extent as in the days of the first revolution and the wars of the great Napoleon. Cadets are educated for the line at St. Cyr, and for the artillery and engineers at the Polytechnique. Below the rank of captain two-thirds are promoted by seniority and one-third by selection, while promotions to majorities are half by seniority and half by selection, and above the rank of major by selection in all cases. Before P. to a higher step the minimum periods of service are two years as second lieutenant, two as lieutenant, four as captain, three as major, and two as lieutenant-colonel. To facilitate P. various ages of retirement have been fixed, varying from fifty-two in the case of a lieutenant, to sixty-five for a lieutenant-colonel.

P. from the ranks is rare in the *German* army. First appointments are obtained by cadets from schools on the nomination of the crown, or by *avantagés* on the nomination of the colonel of a regiment. *Avantagés* enter the army as candidates for the rank of officer, and after six months' service as privates, and the passing of an examination, receive the rank of sword-knot ensign. After six months' further service they are sent to a military school for ten months, and after passing an examination at the end of that time are eligible for regular commissions. P. is at the will of the crown, but is mainly by seniority in the regiment to the rank of captain, and above that rank by seniority throughout the branch, or by selection. Great care is bestowed in the selection of officers for the general staff.

In the *Austrian* army a considerable number of cadets are taken from the ranks, but all officers have to pass severe tests.

In *Russia* the officers are largely drawn from the nobility, but in the line there is a good deal of P. from the ranks.

Pronghorn, or **Prong-buck** (*Antilocapra Americana*), also termed the Cabrit, a species of Antelope, differing from ordinary antelopes, first, in having no accessory hoof, lachrymal sinuses, and inguinal pores; second, in the horns of the male having snags or branches in front; and, third, in the *sheath* of the horn being annually cast or shed and reproduced. The female is hornless. The P. is gregarious, and is common in the Saskatchewan and Missouri districts. It attains the size of a roe deer.

Pro'noun literally means a word used instead of a noun, and this is the explanation of the term commonly given. But, as in the case of other parts of speech, the name inadequately describes the various functions of the P., which is not always a substitute for a mere noun; e.g., it may stand for an infinitive or a clause; the definition would therefore require to be extended at least to

whatever is the grammatical equivalent of a noun. But even this is not satisfactory. Interrogative pronouns representing something yet unknown cannot be supposed to be used 'instead' of that unknown. If we consider the most prominent class of pronouns, viz., the personal, we shall perhaps find in a consideration of their exact force the ground of an acceptable definition. Take the sentence, 'I am weary.' Here the P. 'I,' unquestionably stands instead of the name of the speaker; but it does more than that. It signifies that the person referred to is *in the act of speaking*, a fact not indicated by the use of the name of the person. For this reason Dr. Findlater in his admirable treatise on English grammar in Chambers's *Information for the People*, regards pronouns as 'symbols or highly generalised marks, applied to objects to signify not any inherent attribute, but merely *their relation to the act of speaking*;' and therefore proposes to call them '*relational names*.' It seems to us that no better definition could be given.

The division or classification of pronouns has been the cause of much unprofitable ingenuity, and sometimes of absolute nonsense. Their division into 'Substantive' and 'Adjective' is a mischievous error. What are supposed to be 'adjective' pronouns are not pronouns at all, simply 'adjectives,' and should always be parsed as such. A less objectionable division is that into 'Personal' and 'Relative,' but even this is not precise or exhaustive, though it may be difficult to substitute a better classification. Grammarians are not agreed as to what are the personal pronouns in English. These are usually said to be (1) 'I,' with the plural form 'we'; (2) 'thou,' with the plural forms 'ye' and 'you'; and (3) 'he,' 'she,' 'it,' with the plural form 'they.' About the first and second there can be no doubt; they can stand only for persons. But the so-called third person does not invariably do so. The neuter 'it' represents either an inanimate object or a creature to which personality is not assigned. Hence it is sometimes called the 'neuter,' or 'impersonal' P. Dr. Latham, Mr. C. P. Mason, and Professor Bain prefer to regard 'he,' 'she,' and 'it' as 'demonstrative' pronouns, because they point at the subjects of discourse between two parties, Professor Bain remarking that 'in assigning the class of "he" and "she," though their reference is to persons, the demonstrative function must be held to be the overruling consideration; the use of different words to point to individuals possessing the attribute of sex is an entirely subordinate convenience.' The 'relative' pronouns in English are 'who,' 'which,' and 'that.' Mr. Mason admits that the term is 'bad,' because it is 'insufficient.' He says that the personal pronouns are also 'relative,' i.e., that they relate or refer to some antecedent substantive, but pleads in defence of the term that 'who,' 'which,' and 'that' are 'relative' in a peculiar sense, i.e., that they have a 'grammatically connective force,' since they can 'attach subordinate adjective clauses to some word in the principal sentence.' In regard to the use of 'who' and 'that' there is considerable carelessness exhibited by speakers and writers. 'That' should always be used when the clause which it introduces is restrictive. If this be not done, ambiguity arises; e.g., the sentence: 'It is requested that all members of Council, *who* are also members of the Lands Committee will assemble in the Council-room,' might mean that all the members of Council are members of the Lands Committee, while the true meaning expressed by the use of 'that' is that *such* members of the Council as are members of the Land Committee will assemble, &c.

The interrogative pronouns 'who,' 'which,' and 'what,' used to ask questions, are in a sense 'relative,' but here too it may be urged that their special function warrants their distinctive name. The second and third may be viewed as adjectives, as also the first when in the possessive case. Indefinite pronouns form a doubtful class. These are variously enumerated. Mason gives 'one,' 'any,' 'any,' 'other,' and 'some.' Most, if not all of these, can be properly parsed as adjectives. The first only has a fair claim to be considered a P. When used as follows, 'one may be allowed to say,' it is derived from the French *on* (a corruption of Old Fr. *hom*, Lat. *homo*), and means any person whatever. The so-called 'possessive pronouns' are rather adjectives formed from pronouns than pronouns themselves.

The P. expresses the most abstract relation in language, and has been called 'the highest effort, apparently, of man's generalising powers.' Yet in its origin the P. was by no means an impalpable abstraction. The study of comparative grammar leads to the conclusion that pronouns were originally demonstrative particles

marking relations of place, and in this form were among the earliest elements of language.

See Mason's *English Grammar* (Lond. 1874); Findlater's treatise on 'Grammar' in Chambers's *Information for the People*; Professor Bain's *Companion to the Higher English Grammar* (Lond. 1874).

Proof. See EVIDENCE.

Proof, in engraving, is an early impression from an engraved copper or steel plate, and when it is taken on thin paper, of a pale buff colour, prepared from bamboo stalks, and imported from the East Indies, it is called an *India-P.* In printing, the first impression is called a *first-P.*; after correction, the second is termed a *clean-P.*; then follows a *revise*; and finally a *press-P.*

Proof of Firearms. With a view to the public security, the proving of all barrels for small arms is rendered compulsory either at the proof-house of London or Birmingham. The proof consists in firing them with heavier charges than they are made for. Rifle barrels are proved twice—1st, after boring, with three times the ordinary charge of gunpowder, and a heavy bullet, and 2d, after rifling, with the lock attached, the charge being reduced one-third. When the rifle is quite complete it is again tested with its proper charge. Ordnance is submitted to a very searching proof by firing very heavy and gradually increasing charges, a close examination being made for cracks or flaws. The existence of crevices or honeycomb in the bore is ascertained by means of water, which is forced in under hydraulic pressure; the bore is afterwards wiped dry, and an examination made by means of a mirror for exudation of moisture.

Proof of Gunpowder. See EPROUVETTE.

Proof Spirit, commercial, consists of a mixture of absolute alcohol, 49.24, and water, 50.76 by weight, and its specific gravity is 0.920 at 60°. The name originated from the obsolete plan of testing the strength of spirit by means of gunpowder. Spirit was poured over the powder, and if, on applying a light, the burning alcohol set fire to the gunpowder, the spirit was considered *over-proof*; if it did not, owing to excess of water, the spirit was called *under-proof*. The weakest spirit capable of firing gunpowder in this way is commercial proof spirit.

Propaganda is the popular name of a congregation of cardinals at Rome, the full name of which is Congregatio de Propaganda Fide ('concerning the propagation of the faith'), and which was originated by Gregory XIII. (1572-85). It was finally established forty years after, when it was fully authorised by a bull of Gregory XV., dated June 22, 1622. To this congregation was intrusted the whole superintendence of the missions of the Church to heathen countries, as well as the oversight of the Church in those civilised countries in which there is no properly established hierarchy. The successor of Gregory XV., Urban VIII. (1623-44), established (1627) a great missionary college in connection with the Congregation de Propaganda Fide, in which Europeans are taught the various languages required in carrying on mission-work, and natives of the different countries to which missions are sent are trained for the work of preaching the gospel to their brethren. In connection with the same institution there is also a great establishment for printing Bibles and other literature for missionary purposes.

Propagation of the Faith is the name for missionary enterprise in the Roman Catholic Church. The principal organisation for this purpose is the Congregation de Propaganda Fide at Rome, but in addition to this institution the Association for the P. of the F. was founded at Lyons, 1822, 'for the purpose of assisting by prayers and alms the Catholic missionaries who are engaged in preaching the gospel.' At various times since 1822 the association has been enriched with many indulgences by rescripts of different Popes, and especially by an Encyclical in 1840 which conferred the highest approbation which a work of charity could receive. To assist in carrying forward the work each member of the association says one *pater* and one *ave* every day, and pays a subscription of one halfpenny per week. Two councils, one at Lyon and one at Paris, distribute the funds, consisting of subscriptions and donations collected in all parts of the world, among the different missions, which are established in every quarter of the world. Six times a year the news received from the missions, and a report of the sums collected and distributed, are furnished to the members in a publication entitled *Annals of the Propagation of the Faith*.

Propertius, Sextus—one of the greatest names in Roman elegy—erroneously styled *Sextus Aurelius Propertius*, was born at Asisium (*Asisi*), in Umbria, near the sources of the Clitumnus, some time between 700 and 710 A.U.C. The exact year of his birth is unknown, but 705 seems a probable date, inasmuch as we know that P. was younger than Tibullus (q. v.) and older than Ovid (q. v.). His parents were of the middle class, and had owned an extensive and rich estate of which they had been deprived in the Agrarian division of 713 A.U.C. That P. was a gentleman (*ingenius*) is clear from his mention of the *aurea bulla*—the toy or amulet worn by the children of the freeborn: that he was of patrician descent is a very different matter. In fact his own statement goes to show that he was not. His father died while he was quite a boy: for his training he was indebted to his mother. On assuming the manly gown (*toga virilis*) he repaired to Rome to finish his education. From lack of means the culture of Athens was beyond his reach. P. studied for, and meant to practise at, the bar; but the calling proved congenial. Poetry was his forte: to be called the Callimachus of Rome was the summit of his ambition. He wrote poems on archæological subjects after the manner of the bard of Cyrene, and herein he won high distinction. Love, however, that has so much to answer for, threw the youthful poet into another groove. The first love of P. was a slave girl, by name Lycinna; but this amour was of short duration. The next was a lady of a very different stamp, and to her we are indebted for a work of genius—a collection of elegies replete with tender appeal, sincere affection, burning jealousy, and bitter remonstrance. The lady's name was Cynthia, according to Appuleius: her pseudonym in the elegies, Cynthia. Whatever the character of P. may have been, he was too good for her. Yet she had many recommendations, many charms. She was sprung from an ancestor of literary fame; she was clever, accomplished, musical, handsome, flaxen-haired, dark-eyed; in short, as far as P. was concerned, irresistible. This is the one side of the picture. The other reveals a very different phase of her character; she was extravagant, intemperate, overbearing, unfaithful. Such, we believe, was Cynthia—Cynthia fair and frail—the idol of his heart, the dream of his life, the well-spring of his genius. A woman of this type was sure to break the heart of any man, yet her graver faults, for long, were apparently unnoticed, while they caused wave on wave to well from the tender and forgiving heart of P. Meanwhile the publication of the first book of the Elegies, entitled *Cynthia*, won for P. a place in the brilliant literary coterie of Mæcenas. Like Virgil and Horace, he took up his abode on the Esquiline, where also lay the gardens of Mæcenas. His patron Mæcenas wished to enlist P. to sing the praises of Augustus, but this he again and again declined on the ground of lack of ability. Probably, after all, it was more from incompatibility with his subject and lack of continued application that he did not do so.

Among the literary men of the period P. was ever welcome. Virgil, Ovid, Ponticus, Lynceus, Bassus, Ælius Gallus, and Tullius he numbered among his special friends. The reference to Virgil's great epic (see *Elegy* 26th, bk. iii.) long before its publication is ample evidence of the friendship of the two poets; while the eulogy on the various works of Virgil in the same poem speaks volumes for the heart of P. Athens seems, for many years of the poet's life, to have been one of the sights—indeed, the sight above all which he longed to see. Yet whether he ever went to Greece at all is more than doubtful. He repeatedly threatens to leave Cynthia, and in the 24th *Elegy* of the fourth book Athens is clearly stated as his probable destination. There are no real grounds, however, to bear out the belief that he ever left his native shores. Of the poets who preceded him he mentions Ennius, Varro, Catullus, Calvus, and Gallus—the last four in connection with their loves;—the while avowing his own determination to enshrine Cynthia's name in the amber of imperishable song. To take up the *questio vexata* of Propertian chronology would be useless in an article like this. Those who are interested in the matter may compare the schemes of Barth, Kuinoel, Lachmann, Hertzberg, Paley, and Cranstoun. Suffice it to say that no theory as yet propounded is in all respects satisfactory. For the same reason we dismiss the question of the division of the writings of P. into books. For the general reader it matters not—supposing even all the elegies to be included—whether they are in four, five, or forty books. A much more interesting and crucial question is the

determination of the beginnings and endings of many of the pieces, and of the proper order of the distichs, especially in books iii. and iv.

This is not a biography of Cynthia, yet it is not unbecoming here to notice the end of that much-beloved and much-abused *meretrix*. At her death P. had deserted her. After she was burnt on the pile P. seems to have appropriated her little trinkets, such as brooch and personal ornaments, and to have given them to a disreputable frequenter of the *Via Sacra*. We can hardly imagine that after all this, P. contracted a lawful union, notwithstanding the Younger Pliny's express testimony that Passennus Paulus was a lineal descendant (*vera soboles*) of P., and also an inheritor of his genius. How P. spent his last years we know not. From his own writings we can trace his life no farther than A.U.C. 739. As to whether he ceased to live when he ceased to write it is vain to speculate. At the early age of thirty-four his sun had set for literature and poetry—four years after Virgil and Tibullus had gone to their rest, while Horace and Ovid were in the heyday of their popularity and fame.

A word as to the character, work, and genius of P. The value of the first a careful reader must by this time have learned. His failings in our eyes were venial in his period. His work is immortal. He is certainly, whatever may be said by connoisseurs and verse-makers to the contrary, the greatest of the elegiac poets of Rome. This is not the place to discuss the relative endings of the pentameter, whether the dissyllabic, trisyllabic, quadrisyllabic or pentasyllabic is the best; but it is surely the place in which to state the conclusion to which one has come after long study of the subject for or against the Tibullian and Ovidian distich. The distich of Tibullus is unequalled for tenderness, terseness, and pathos; that of Ovid has a melody peculiarly its own—sweet, winsome, fascinating. Both are very lovely, but they are apt to become tiresome. P. belongs, so far as his strings echo music, to an older school—the school of Lucretius. One word as to the genius of P. In the poetry of pure passion he is second to Catullus alone. He lacks the sweet grace and tender melancholy of Tibullus, the easy flow and melodious chime of Ovid; but his verse is his own—strong, nervous, sparkling: every line reflects the man. His originality is unquestionable and his music genuine. He is the heathen representative of Christian tenderness. He was born to suffer sorrow, to realise the worthlessness of transient pleasures and the vanity of voluptuous dreams. He had not, it is true, at thirty-four, any more than Burns at thirty-seven, attained his true moral stature; but he departed to the land of shadows with his native strength unabated, his youthful splendour undimmed, and the unfading laurel round his brow.

The *editio princeps* of P. was published in 1472; where is uncertain. The editions of Scaliger, Barth, Kuinoel, Lachmann, Jacob, Hertzberg, Haupt, and Müller show progressive degrees of advancement in Propertian criticism. Paley's edition—inaccurate in many respects, yet a wonderful mass of research—is by far the most valuable. The recent papers by Professors H. A. J. Munro and Robinson Ellis on P. possess an inestimable value for scholars generally. The only two English translations deserving of mention are those of Charles Robert Moore, M.A. (Livingtons, 1870), and James Cranstoun, LL.D. (Blackwood, 1875), the latter being the only complete version of the Umbrian poet in the English language. Of French translations the best is that by St. Arnaud (Bourges et Paris, 1819). In German the versions of Hertzberg (Stuttgart, 1838), and of Jacob and Binder (Stuttgart, 1860), both in the original metres, are excellent. The reader may also consult with advantage the Rev. J. Davies' *Catullus, Tibullus, and P.*, in Blackwood's *Ancient Classics for English Readers* (1876-77). Cf. also Professor Munro's papers on P. in the *Journal of Philology* (vol. vi. *passim*).

Proph'ets, according to the popular idea, were men who predicted future events, the only difference between true and false P.—e.g., between the Jewish P. and those among other nations—being that in the case of the former the actual fulfilment of their prophecies proved that they had really been supernaturally enabled to foretell the events. But whatever truth there may be in this, it is beginning to be acknowledged that it is a false conception of the prophetic office to regard prediction as the chief function of P. This idea is in no way implied in the etymology of the various names. The meaning of the general Hebrew

title *Nabi*, is given by the best authorities as 'one in a state of ecstasy,' 'a clear, loud speaker,' 'a spokesman' or 'interpreter' (cf. Ex. iv. 16, vii. 1), and it indicated one to whom God manifested himself, so that he was able to declare the will of God to men. Indeed the meaning is thus defined by other phrases: 'interpreter' (Isa. xliii. 27), 'messenger of Jehovah' (Hag. i. 13), 'man of God' (1 Sam. ii. 27, ix. 6, &c.), 'man of the spirit' (Hos. ix. 7). Very much the same meaning attached to the Greek *prophētēs*, which was the term applied to those who understood the broken and dark sayings of the *mantis* or diviner when in a state of ecstasy, and explained them to others; although the latter was sometimes also called *prophētēs*. Even the other Hebrew names *Roeh* and *Chouch*, 'seer' (cf. 1 Chron. xxix. 29, in which all the three occur), have no special reference to the future, but merely imply that these men could see into the divine counsels and mysteries, and could thus explain them to others; what they uttered being called a 'vision.' The name *Roeh* seems to indicate the personal insight of individuals living in a state of seclusion; *Nabi*, to allude to the utterance of what they knew when they began to lead a more public life; and the latter came into general use in the time of Samuel (1 Sam. ix. 9), in whose time it was that they came to be regarded as a special class, although the name of seer continued in use after his time. The Hebrew names given above all denote the 'office of watching over passing events, and of lifting up the voice of warning, of reproving, of encouragement at the proper time.' The Greek *prophētēs*, in the sense of foreteller, was given as the equivalent of *Nabi* in the LXX. (about B.C. 280).

1. *First Period* (about B.C. 1100-800). The real prophetic age is held to have begun with Samuel (cf. Acts iii. 24; Heb. xi. 32); but it is not to be supposed that prophecy was called into existence at this time, far less that Samuel was the means of calling it into existence. On the contrary, it was distinctly recognised that there had been persons, male and female, before endowed with the same spirit; e.g., Abraham (Gen. xx. 7) and the patriarchs generally (Ps. cv. 15), Moses (Deut. xviii. 15, xxiv. 10), Miriam (Ex. xv. 20), Deborah (Judges iv. 4); cf. also Judges vi. 8; 1 Sam. ii. 27. But it was in his time that associations began to be formed of zealous adherents of the national deity, analogous to those of the prophets of Baal and other Canaanitish deities (cf. 1 Kings xviii. 19). They wandered about in bands (1 Sam. x. 5, 10), and lived together in a kind of cloister (1 Heb. *naioth*, 1 Sam. xix. 18, 19), under a head or 'father' (like the first Christian monks under their *abbas*), being known as 'sons of the P.' The name given to those communities—'schools of the P.'—has misled people to think that the members received regular instruction, whereas prophecy, especially as understood in those primitive times, was an art or profession which could not be learned. For this very reason the official order of P. formed in Israel degenerated. The number of men whose spirituality of mind and intensity of moral nature raise them to such a level above their fellow-men as to render them in any real sense interpreters of the will of the deity are necessarily few, and a whole community of such is inconceivable. They would inevitably be inferior imitators of the first P., and generally of a lower standard. One distinct cause of degeneracy was the notion of the superstitious multitude that the P. were mere soothsayers, from whom information not obtainable by ordinary means might be conveniently got with respect to all possible matters—e.g., how something lost was to be found (cf. 1 Sam. ix. 6), whether an expedition should be made (Judges xviii. 5), or a campaign undertaken (1 Kings xxii.), &c., an official called the king's seer being part of the royal establishment, doubtless for consulting in such emergencies (1 Chron. xxi. 9; 2 Chron. xxix. 25).

2. *Second Period* (about 800-640). By the beginning of the 8th c. B.C., the official order of P. was identified with the aristocratic sacerdotal party, both in Judah and in Israel. The political tactics of this party was to maintain the national existence by means of foreign alliances—with Assyria and Egypt. The sacerdotal religion stood mainly by rites and ceremonies, many of which were common to the Israelites with the Canaanites. And worse than that, the religious conceptions of the great mass of the people were essentially Polytheistic. The God of Israel was simply one among the many deities worshipped by the neighbouring nations. The morality of the people generally had sunk to a low ebb. It was at this time, about the middle of the reign of Jeroboam II. (B.C. 823-873), that a new order of P.

appeared—including the names of Joel, Amos, Hosea, Micah, Isaiah, and perhaps Nahum—some of whom belonged to the lower orders (e.g., Amos and Micah), and not to the official order of P. at all (cf. Amos vii. 14), but all of whom identified themselves with the democracy. They condemned all foreign alliances (cf. Hos. v. 13, vii. 11, xii. 1, xiv. 3; Isa. xxx. xxxi., &c.). They brought accusations against kings, princes, judges, and even priests and prophets. They maintained that the true service of God consisted not in offering sacrifices and observing festivals, but in fervent piety, a pure morality, and kindness to the poor and friendless (cf. Isa. i. 10-17; Hos. vi. 6; Amos v. 21-24, &c.). And above all, their religious conceptions were a pure monotheism. Jehovah was the one God of the whole earth (Hos. xiii. 4, &c.). This period has been called the golden age of Hebrew prophecy.

3. The great P. of the third period (B.C. 640-400) were Jeremiah and Ezekiel, but in the writings of these two are perhaps best exemplified the nature of the decline which took place in this period. With the former P. writing was only the fruit of public speaking, a continuation and supplement of the true prophetic work, but in this last period the P. were writers chiefly. Hence the prophecies of the latter, although they may be more polished pieces of literature than those of the former, not being produced under the same fervent heat of inspiration, are of a lower type. Some critics profess to be able to detect another symptom of degeneracy in a compromise, on the Jehovistic side, between the P. and the priests in the time of Josiah (B.C. 640-609), the expression of which was the Book of Deuteronomy, and another compromise, on the sacerdotal side, after the Captivity, in the Book of Leviticus.

In the Hebrew canon, the P. are divided into the *former*—Joshua, Judges, Samuel, Kings—and the *latter*; the *latter*, again, into the *greater* (referring entirely to the size of their books)—Isaiah, Jeremiah, Ezekiel; and the *lesser*—Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habakkuk, Zephaniah, Haggai, Zechariah, Malachi. In the New Testament times there was no regular order of P. like the Apostles, but certain men and women were endowed with 'the gift of prophecy' (cf. 1 Cor. xii. 10, 28, xiv. 3; Acts xxi. 9). It has been supposed that what properly corresponded to the old prophetic gift was the gift of tongues (Acts ii.), the connecting link between the two being the ecstasy or trance which accompanied both. Whatever was the form of the prophetic gift, the historian Eusebius informs us that it had ceased in his day (about A.D. 350). See Davidson's *Introduction to the Old Testament* (Lond. 1862), Stanley's *Jewish Church* (new ed. Lond. 1876), Ewald's *Die Propheten des alten Bundes* (Eng. trans. Lond. 1875), Kuenen's *Religion of Israel* (Eng. trans. Lond. 1874), and *P. and Prophecy in Israel* (Eng. trans. Lond. 1877).

Proportion, in Arithmetic, is a rule by which a number may be found which bears to a given number the same ratio which exists between other two given numbers. The whole theory of proportionality is a special branch of algebra, and as such will be considered here. Its only logical basis is to be found in the definition given by Euclid, which is as follows:—If there be four magnitudes, and if any equimultiples whatsoever be taken of the first and third, and any equimultiples whatsoever of the second and fourth, and if, according as the first is equal to the second, greater than it, or less, the third is likewise equal to the fourth, greater than it, or less—then the first of these magnitudes is said to have to the second the same P. which the third has to the fourth. For instance, let the four magnitudes be

$$A, B, C, D \quad \text{and let} \\ nA, mB, nC, mD$$

be the equimultiples, taken in accordance with the definition. Then if, whatever n and m may be, nA and nC are similarly related, as regards magnitude, to mB and mD respectively, the proportionality must hold that

$$A : B :: C : D.$$

This definition, though at first sight lumbering, is the only perfect definition of P. which has yet been given, and all attempts at putting it in a shorter or simpler form have completely failed. Apparently qualitative only, it is rigidly quantitative when developed logically, as in the fifth book of the elements of Euclid, which is the foundation of the whole of algebra. The $P. a : b :: c : d$

is ordinarily written $\frac{a}{b} = \frac{c}{d}$, or $ad = bc$. A fraction is simply

another name for a ratio or P., and two fractions are equal when the numerators and denominators taken alternately satisfy the definition. See FRACTION.

Proposition (Lat. 'a placing before'), in Logic, the expression in words of the result of a comparison or act of judgment. It affirms or denies some word or combination of words of some other word or combination of words. These, respectively known as the *predicate* (Lat. *predicatum*, Gr. *katēgoroumenon*, 'the thing affirmed') and the *subject* (Lat. *subjectum*, Gr. *hypokeimenon*, 'the thing lying under'), are, after Aristotle, called the *terms* (Lat. *termini*, Gr. *horoi*, 'limits') of the P. The connecting verb, whether qualified or not by the negative particle, is named the *copula* (Lat. 'band'). The office of the P. being simply to express a judgment as to the compatibility or incompatibility of two notions, the Logical Copula (q. v.) is limited to the present tense of the verb 'to be,' apart from the notion of existence, and employed simply as a connecting particle. Many have argued that the copula may be so modified as to express the nature of the judgment and the degree of assent to or dissent from the P. (see Mill's *Logic*, vol. i. chap. 4, § 2), but it seems simpler to take the form 'A is' or 'is not B' as the ultimate form of all propositions (see Hamilton's *Review of Whately's Logic* in his *Discussions on Philosophy*, and Mansel's *Prolegomena Logica*, p. 63). A P. may thus, according to its quality, be either *affirmative* or *negative*. In quantity, i.e., according as the predicate is affirmed or denied of all or of only a part of the individuals denoted by the subject, it may be *universal* or *particular*. Combining the two divisions, we have four forms, viz., *Universal Affirmative* ('All S is P'), *Particular Affirmative* ('Some S is P'), *Universal Negative* ('No S is P'), and *Particular Negative* ('Some S is not P'). Sir W. Hamilton, maintaining that in thought the predicate is quantified as well as the subject, substituted for this scheme another of eight forms (see his *Lectures on Logic*, and the Appendices to his *Discussions*), fully criticised by Mill in his *Examination of Hamilton's Philosophy*, chap. xxii. An affirmative P., in which the subject is a common or an abstract term, may be either *verbal* (the 'essential' P. of the schoolmen) or *real* (the 'accidental' P. of the schoolmen), according as it states explicitly what is implicitly contained in the subject (as 'All triangles are three-sided figures'), or affirms what could not be gathered simply from the consideration thereof (as 'Some metals are elements'). The same distinction is expressed by the 'Analytical and Synthetical Judgments' of Kant, and the 'Explicative and Ampliative Judgments' of Hamilton. On the vexed question of the Nature and Import of Propositions, or Theory of Predication, see Hobbes' *Computation or Logic*, chap. iii., and Mill's *Logic*, chaps. v. and vi.

Prosecution, Criminal, in English law. See under CRIMINAL, CRIMINAL PROCEDURE. In England, there is no public prosecutor, as in Scotland, except, in certain cases, the Attorney-General (q. v.). Hence it happens that crime very often goes unpunished, private persons being naturally reluctant to take upon themselves the trouble and expense of prosecuting for the good of society. The expense is supposed to be repaid by the county, but the repayment is seldom a third or even a quarter of the real expense. But the prosecution may fail, even though morally entitled to succeed; then an action may be brought or threatened for malicious prosecution, or for false imprisonment. There are unscrupulous law-agents infesting the courts always ready to take up a case of this kind on speculation. The defendant then has this alternative before him, either to submit to an extortionate and wholly unjust demand under name of damage, or to enter upon the protracted anxiety of a lawsuit, should he lose which, he will not only have to pay the plaintiff say £100, but he will have to meet the whole enormous expense of a jury trial; and should he win, as he will probably find the plaintiff a bankrupt at the end of the business, he will at least have to pay his own costs, besides having had the anxiety, to many worse to bear than the pecuniary loss. In Scotland there is a well-organised system of P. C. See ADVOCATE, LORD; PROCURATOR FISCAL.

Proselytes is the name used in the New Testament and LXX. for converts from heathenism to Judaism, the Hebrew word (*ger*) being in the Old Testament translated 'stranger.' In the later times of Judaism there seems to have been a sana-

tical desire to proselytise which did not exist at an earlier period, although provision was made in the Law for their admission (cf. Exod. xii. 48; Lev. xvii. 8; Numb. xv. 15). And it seems that the artificial Jews thus made were anything but a credit to the nation. Very often they only exhibited the vices of the Jews engrafted on the vices of the heathen. A distinction has been drawn by Rabbinical writers between 'P. of Righteousness,' 'Sons of the Covenant,' or 'full Israelites,' and 'P. of the Gate,' the latter class being those who had become worshippers of Jehovah, and agreed to observe the seven so-called Noachic precepts against idolatry, blaspheming, bloodshed, uncleanness, theft, disobedience, and eating 'flesh with the blood thereof,' but had not submitted to circumcision. It has been denied, however, that the latter were found at all in Old Testament times, or that they were ever P. in any real sense. The rites for the admission of P. were circumcision and baptism, followed by the same offering as was made for a birth (Lev. xii.), the baptism being called a new birth.

Proserpina. See CERES.

Prosody (Gr. *prosōdia*, belonging to song) is that part of grammar which treats of quantity, accent, and harmony in metrical composition; in a word, it treats of Verse. M. Guyard, in his *Théorie nouvelle de la Métrique Arabe* (Par. 1877), has not only rendered intelligible Arabic P., but by his method, which applies equally to other languages, has for the first time reduced P. itself to the limits of an exact science.

Prossnitz (Czech *Prostějov*), a town of Moravia, Austria, on the river Rumza, 14 miles S.W. of Olmütz by rail. It has manufactures of cottons, woollens, linens, sugar, brandy, rosoglio, and has considerable trade in flax, corn, cattle, asparagus, and geese. Pop. (1875) 15,787.

Prostitution, Female, is not a legal offence, but in the metropolis, a statute of Elizabeth has been revived for the purpose of bringing the keepers of brothels under magisterial notice. 2 and 3 Vict. c. 47 authorises the police of London to apprehend, without warrant, any woman loitering and annoying passengers in the street during the night. In all the large cities of the United Kingdom the local authorities have, it is believed, power to enforce similar regulations, and to suppress houses of bad character causing annoyance to the neighbourhood.

Prostyle, in Grecian architecture, a building in which the pillars of the portico stand free from the front wall. A building with a portico at each end is called *amphistylus*.

Protágoras, a celebrated Greek philosopher, born about 480 B.C. at Abdera in Thrace, was once, according to the popular but probably baseless story, a poor porter, who attracted the notice of Democritus by the skill with which he poised a bundle of wood upon his shoulders, and from him received his earliest instruction in philosophy. He seems to have come to Athens prior to 445, here formed a close intimacy with Pericles, and was the first to assume the name of 'sophist' and teach for hire, amassing thereby a fortune which became proverbial. We gather that he was an eyewitness of the plague (430), but the date of his visit to Sicily and many of the towns of Greece is unknown, as also is that of his expulsion from Athens and the burning of his books in the Agora. The impeachment of which this sentence was the result, according to Diogenes Laertius, was founded on a passage in P.'s treatise *Peri Theōn*: 'Of the gods I am not able to know either that they are or that they are not; for many things prevent us from knowing it, the darkness and the shortness of human life.' Frei, however, maintains with some plausibility that P. was accused by Pythodorus during the government of the Four Hundred, i.e., in 411, and that his death must be ascribed to the same period, as Euripides (who died in 406) alluded to it in the *Ixion*. Starting from the Heraclitean maxim that motion is the all-pervading principle, and that nothing exists, but everything is constantly coming into existence, P. proceeded to distinguish two kinds of motion, an active and a passive, from whose concurrence come sensation and what is felt, perception and what is perceived. For the individual or sensation-receiving subject, that only can be true which he himself perceives, and since to one man an object may present itself as good in which another sees only evil, either view being equally justifiable, knowledge becomes impossible. From this dilemma P. sought to escape by postulating a better or worse

condition in the percipient subject, a condition, moreover, for whose improvement rules might be prescribed; and he explained how the virtues, of which he admitted five, were due to innate modesty and justice, developed by education and instruction. P.'s writings have perished, but from a list of them preserved by Diogenes Laertius (ix. 55) we see that they comprised ethics, politics, and miscellaneous subjects, the chief treatises probably being the *Alētheia* ('Truth'), and *Peri Theōn* ('Concerning the Gods'). See J. Frei's *Quæstiones Protagoræ* (Bonn, 1845), and Wayte's edition of the *P.* of Plato (Lond. 1871).

Protea is an extensive order of dicotyledonous large or small trees or shrubs, almost entirely confined to the southern hemisphere, where they have a wide range as well in latitude as in longitude and elevation, forming in Australia and S. Africa one of the most striking features of the flora. The plants are remarkable for their rigid foliage, and the union of an extraordinary diversity of aspect (hence the name *P.*), with a more than ordinary similarity in the structure of the organs of reproduction. But a small number yield useful products beyond their timber for firewood, or in some species in which it is beautifully mottled, for cabinet work; many, however, are much admired as botanical curiosities, and have been introduced into public and amateur collections in Europe—Kew, for instance, at one time possessing 155 species. The most familiar genera are *Banksia* (q. v.), *Dryandra*, *Grevillia*, *Hakea*, *Persoonia*, *Protea*, *Telopea*, &c.

Protection. See CORN-LAWS and FREE TRADE.

Protector, in English history, a title borne by four regents, viz., William, Earl of Pembroke (1216-19), regent for Henry III.; Humphrey, Duke of Gloucester (1422-47), regent for Henry VI.; Richard, Duke of Gloucester (1483), regent for his nephew, Edward V.; and Edward Seymour, Duke of Somerset (1547-49). The title of Lord P. was conferred by Parliament on Oliver Cromwell, December 16, 1653, and after his death in 1658 passed to his son Richard, who voluntarily resigned it, May 25, 1659.

Protein, the name given by Mulder to what he conceived to be an essential constituent of albumen, fibrin, casein, and albuminoid substances generally. The word now exists only in its adjective form, the proteic group being synonymous with the albuminoid group.

Protest, Notarial, is a legal instrument drawn up by a notary, intimating some legal penalty against a party who has failed in an obligation. It is most commonly applied to the notarial evidence of presentation and failure to pay a Bill of Exchange (q. v. under BILL).

Protestants was the name applied to the minority in the second Diet of Speier (1529), who protested against the substitution for a resolution passed at the first Diet (1526), which had granted to the German princes the management of religious affairs within their own dominions until the meeting of a general council, of an edict declaring all change in doctrine, discipline, or worship unlawful until they had been sanctioned by a general council. The P. were the Elector of Saxony, the Markgraf of Brandenburg, the Dukes (Ernst and Franz) of Brunswick-Lüneburg, the Landgraf of Hessen, and the Graf of Anhalt. Their appeal to the emperor and a general council of the German nation was afterwards subscribed by fourteen cities—Strassburg, Ulm, Nürnberg, Constanx, Reutlingen, Windsheim, Memmingen, Lindau, Kempten, Heilbron, Isny, Weissenburg, Nördlingen, and St. Gall. The name was afterwards assumed by the Lutheran and other Reformed Churches generally, to distinguish them from the Roman Catholics.

Proteus, in Greek mythology, the old man of the sea who tended Poseidon's flocks of seals, and with the gift of prophecy combined the power of assuming a hundred different shapes. At noonday he rose from the waters to slumber on the shore of Pharos or Karpethos, and then was the time to come upon and hold him fast, till, wearied with fruitless metamorphoses, he consented to reveal the future. A later myth made P. an Egyptian king, who took from Paris the true Helen, and gave him a phantom in her stead.

Proteus, a remarkable species of *Amphibian* Vertebrates belonging to the order *Urodela* and group *Perennibranchiata* (q. v.), or that in which the gills of early life remain, so that the

animal breathes by gills and lungs in its adult state. The *P. anguinus* (or *Hypochiton anguinus*) is the only well-defined species. It inhabits certain underground caves in Central Europe, and is found in the caves of Adelsberg. Its length is about 12 inches, the body being long, slender, and of a pale flesh colour. Three bright red external gills spring from each side of the neck. The eyes are small, and the teeth rudimentary. The front limbs have three, and the hinder limbs two toes. The P. is allied in its nature to the curious Axolotl of Mexico and to the Sirens or mud-eels of the Carolina rice swamps.

Proteus Animalcules, a name formerly applied to the various kinds of *Amæba*, animals belonging to the class *Rhizopoda*, of the sub-kingdom *Protozoa* (q. v.). The *Amæba* exist as minute specks of structureless *protoplasm* or *sarcodæ*, and derive their name from their habit of continually altering the shape of their body by pushing out processes of their body-substance.

Prothall'us (Gr. *pro*, 'forth,' and *thallos*, 'a young shoot'), a term used by botanists to denote the first results of spore germination in the higher cryptogams. This is a kidney-shaped membrane in ferns, a bulb-like form in adder's tongues, and a bundle of adnate threads in horsetails. In all these cases the new plant springs from the impregnation of a cell in peculiar organs called archegonia.

Protococcus (Gr. 'first grain'), is a genus of minute unicellular *Alga*, consisting of species composed of single cells more or less enveloped in a gelatinous covering of cellulose, through which protrude two vibratile cilia. They move rapidly, and are multiplied with great rapidity while in motion by cell division. Eventually the individual becomes quiescent, retaining, however, its vitality even when dried up, and resuming activity even after a lapse of years when placed in water. P. is abundant in mud where rainwater collects, and in like situations. The colour varies from bright green to bright red, according to the colouring matter diffused throughout the protoplasm, or occurring in the form of granules. See RED-SNOW PLANT.

Protocol (Low Lat. *protocollum*, late Gr. *protokollon*, from *prōtos*, 'first,' and *kolla*, 'glue'), was originally the outer leaf attached to the Byzantine papyrus rolls, and bearing an inscription stating by whom and under what 'comes largitionum' each was issued. The name was afterwards given to the public records, which, by edict of Justinian, were always accompanied by a P. In France a P. is a formulary for public documents. In Scotland it formerly meant the record book in which a notary-public was required to insert copies of the instruments he executed. In diplomacy, it denotes the original copy of a despatch or treaty, as the P. prepared in London during the visit of General Ignatieff in March, and repudiated by the Turks in April 1877.

Protogenæ (Gr. 'first-born'), a granitic rock very abundant in the Alps, differing from true granite in having the mica replaced by talc. It derives its nature from having been at one time regarded as the earliest formed granite.

Protopheres, a famous Greek painter, was born at Kaunos in Caria, and was a contemporary of Apelles and Aristotle. He lived for the most part at Rhodes, where he was not sufficiently appreciated until Apelles publicly offered to buy his numerous unsold pictures for a large sum, after which the Rhodians purchased P.'s pictures for the sums Apelles had offered. All his pictures were remarkable for careful and brilliant finish. The chief was the 'Ialysus and his Dog,' others were 'A Satyr Resting and Holding his Pipes,' 'The Paralos and Ammonias,' and 'The Thesmoetheæ.'

Proto-Notary (Low Lat. *proto-notarius*, 'first notary'), an officer at Rome, appointed by the Pope, and charged with registering the acts of the Church. Their number was fixed at twelve by Sixtus V., and they enjoy many special privileges.

Protoplasm, the name applied to the homogeneous living matter of which the bodies of animals and plants in their earliest stages of development consist. P. is also found within the cells of animals and plants in their young and active condition. It was first clearly demonstrated to occur as the delicate inner

lining of plant-cells by Schleiden and Mohl, and succeeding chemical and microscopic research revealed its uniform composition and its widely diffused nature throughout the bodies of all animals and plants. Thus the essentially living part of a yeast plant, the body of an *Amœba*, or *Foraminifer*, or other low animal, the cell-contents of higher animals in their perfect condition, and the cell-contents and active parts of plant structure, consist equally of P. A minute speck of P. (as seen in an amœba) may constitute of itself a complete animal. P. is also known as *sarcodæ* and *bioplasm*. Chemically it is an *albuminous* compound, composed of carbon, hydrogen, oxygen, and nitrogen, with minute traces of sulphur and phosphorus. The community of P., when viewed microscopically or chemically, and wherever found, forms one of its most remarkable features. Physically it coagulates when exposed to a high temperature (40° to 50° C.), and contracts when electrical currents are passed through its mass. The interest which has centred around this substance chiefly arises from the consideration of its relations to *life* and *vital action*. One view of these relations is that life is a *property* of P., just as contractility may be assumed to be a quality of this substance. Carbon, hydrogen, oxygen, and nitrogen—so runs Huxley's argument—are lifeless bodies; when brought together in certain proportions they form P., and this P. exhibits vital phenomena. Thus these vital phenomena are regarded as the sequence of the formation of P. from inorganic or lifeless elements. 'We do not assume,' says Huxley, 'that something called "aquosity" enters into and forms water when its component gases, hydrogen and oxygen, are brought together.' What better reason, then, is there for assuming a principle of 'vitality' than of 'aquosity'? The reply to this is that we know fully and perfectly the laws and conditions under which water is formed; and require to postulate no force, other than the chemical affinity of hydrogen and oxygen in order to account for its formation. But the living body is the seat of forces which, as far as science has yet demonstrated, can be explained or produced by no known combination of physical and chemical forces. We are obliged to postulate the existence of a new force in accounting for the actions and development of living matter, and this force we term *vital force* or *life*.

Protornis (Gr. 'first bird'), a genus of fossil *Insectorial* or Tree-Perching Birds. The *P. Glaricus* of the Eocene deposits of Switzerland represents the oldest known fossil of Insectorial birds. P. appears to have been related to the existing Larks.

Protozoa (Gr. 'first animals'), the lowest sub-kingdom or group of animals. The characters of these animals (represented by the *Amœba* or 'Proteus-animalcule,' *Foraminifera*, *Sponges*, *Infusoria*, &c.) are mostly negative. They are destitute of digestive, circulatory, and nervous systems. Only in the highest group, that of the Infusoria, is a mouth present. Their bodies consist of masses of *protoplasm*, or *sarcodæ* in its simplest and most primitive condition, and a mere speck of this material may constitute at once a living animal or a *protozoon*. Many of the P. are still doubtfully regarded as animals. Some of the *monads*, for example, may be either animals or plants. The protoplasm of which the bodies of P. are composed may be contractile and highly mobile in its character, as in amœba and foraminifera, or the body may have a definite outline, as in the infusoria, and the protoplasm cannot be protruded as in amœba. Locomotion in such cases is subserved by the minute vibratile filaments known as *cilia*. Digestion in the P. appears to be subserved by the formation of temporary spaces in the sarcodæ or protoplasm of the body; such spaces being named *food-vacuoles*. Certain clear spaces are also seen in the bodies of P., and are noticed to exhibit pulsations. These are accordingly termed *contractile vesicles*, and are supposed to represent *rudimentary hearts*. Pigment spots exist in Infusorians, and may represent rudimentary sense organs; but no traces of nerves are present. *Reproduction* in P. may take place by *fission* or simple division of the body-substance (as in amœba and infusoria); by *gemmation* or *budding*, in certain infusoria; and by a third process, the nature of which is as yet imperfectly understood, but which appears to be allied to sexual reproduction. In the latter instance, the body appears to undergo encystation and segmentation, the particles set free by the subsequent rupture of the body developing into young P.

The classification of the P. varies according to the structures

taken as the basis of arrangement. They may be divided into the *Stomatous*, or 'mouth-possessing P.', represented by the Infusoria; the *Astomatous* P. including the other groups of the sub-kingdom. The P., however, are usually divided into three or four classes. The following table gives the most recent classification of the group:—

Classification of P.	Section A.—MONERA (P. destitute of a nucleus).	Section B.—ENDOPLASTICA (P. possessing a nucleus).	Classes.
			<ol style="list-style-type: none"> 1. <i>Monera</i>. 2. <i>Foraminifera</i> (?). 3. <i>Radiolaria</i>. 4. <i>Gregarinida</i>. 5. <i>Rhizopoda</i>. 6. <i>Spongiæ</i>. 7. <i>Infusoria</i>.

Proud-Flesh is the popular designation for too luxuriant granulations arising from wounds or ulcerated surfaces. P.-F. should be treated by astringent applications, as with nitrate of silver or sulphate of copper, either in the solid form or in strong solution.

Proudhon, Pierre Joseph, son of a cooper, was born at Besançon, January 15, 1809. His earlier years were spent in herding cows and picking up coppers necessary for his sustenance as one of a poor family of five. Some education, however, he received at a local school before entering a printing-office, where he improved his leisure by reading. At the same time his own poverty drew his thoughts towards the whole problem of social inequality, and gave a bias to all his subsequent speculations. Until 1837 he continued to labour in different provincial workshops, where he introduced a new feature in topography along with MM. Lambert and Maurice, and made his first serious contribution to literature in his *Essai de Grammaire Générale*. General theological productions followed, for which he was rewarded by the Academy at Besançon giving him a three years' pension of 1500 francs. In 1840 appeared his most characteristic book, *Qu'est-ce que la Propriété*, in which he broached the startling theory in political economy that property is robbery. Next year he published *Avertissement aux Propriétaires*, was prosecuted for it at Besançon and acquitted. He then worked at Lyon for five years in the direction of a water-transport system on the Rhône and Rhône, publishing meanwhile two volumes on political economy. In 1848 he was attracted to Paris by the outbreak of the February revolution, accepted the editorship of a newspaper *Le Représentant du Peuple*, and attained so rapid a popularity that he was returned in June for one of the departments of the Seine to the Assembly. Here he attempted to realise in practice his doctrine of property, but representatives declined to listen to him, so that he was compelled by means of a thrice-suppressed journal to agitate elsewhere. He established, January 1849, a *Banque du Peuple*, with the object in view of suppressing capital, but being compelled to fly to Geneva for a press offence, it was brought to a summary close. Having returned, he married in 1850 whilst a prisoner at U'Pelagie, continuing to pour forth treatise after treatise on financial and revolutionary subjects. In 1858 appeared *De la Justice dans la Révolution et dans l'Eglise*, which contained so many political and religious heresies that he had to retire to Belgium, from whence he continued to issue pamphlets obnoxious to authority. P. died at Paris, January 19, 1865. See Clement's *P., sa Vie, ses Œuvres, et sa Correspondance* (1872).

Prout, Father. See MAHONY, FRANCIS.

Provence (Lat. *Provincia*), an old province of France, now divided into the departments of Bouches-du-Rhône, Basses-Alpes, Var, and part of Vaucluse. It has always been famous for its fine climate, its roses, and its fruits; but the fact is that the climate, especially in Upper Provence, is very changeable. Though the spring is very early, it is often checked by a series of cold N.W. winds, known as the *Mistral*, which retard and destroy vegetation.

Provençal Language and Literature. The two Romance dialects of Gaul, French (q. v.) and Provençal, appear to have been originally almost identical, none of the divergent features peculiar to the latter, or shared by it with Spanish or Italian, being sufficiently important to constitute an essential difference. The northern dialect, however, was more exposed to Teutonic influences than the southern, and accordingly Provençal still retains certain archaic features, both in its grammar and vocabulary, which bring it closer to Latin, so that it holds a position between Italian and French much the same as geo-

graphically Provence holds between France and Italy. Mutual jealousy, so common to near neighbours, helped to widen the breach between the *Francigenæ* and *Provinciales*, and in 1229 we find a notary of Albi pleading his inability to decipher the inscription on a seal, because it was written 'in lingua Gallica vel alia nobis extranea,' just as the *Leys d'Amor* of the 14th c. classes French with English as a foreign tongue. To the two rival if kindred dialects were given the name *Lengua d'Oc* and *Langue d'Oïl*—*oc* (Lat. *hoc*) being the sign of affirmation in Provençal, as *oïl* (Lat. *hoc illud**) in French; whilst by the Troubadours their language is sometimes styled *Romans* or *Lemosin* (Limousin). It was spoken in Southern France from the Loire to the Mediterranean and from the Alps to the Pyrenees, extending beyond these limits eastward as far as Venice, and in a south-westerly direction over north-eastern Spain and the Balearic Isles. Of the sub-dialects of Provençal, that of Toulouse was the most harmonious, that of Piedmont the first to be committed to writing, if the *Nobla Leyczon*, a Vaudois paraphrase of portions of the Gospels, really belongs to the opening years of the 12th c. Mr. Bradshaw, however, who in 1862 discovered this along with the other Vaudois MSS. of Morland, Cromwell's secretary, in the Cambridge Public Library, has established almost beyond a doubt the 15th c. as the period of its composition. The earliest monument of Provençal itself, anterior to the 10th c., is the fragment of a poem on Boethius, edited by Raynouard (Par. 1817). To Raynouard belongs the credit of having been the first to study the language of his country critically, though its archaisms misled him into believing that it only was the daughter of Latin; French, Italian, and Spanish being modifications of Provençal. His theory was successfully refuted by August von Schlegel and Sir Cornwall Lewis, who pointed out that in some points the *Langue d'Oïl* was more archaic than the *Lengua d'Oc*—e.g., that *sommes*, *êtes* (*estes*), and *sont* could never have come from *sem*, *etx*, and *son*. The Albigensian Crusade, the removal of the Papal See from Avignon, and the final absorption of Languedoc into the French monarchy, degraded Provençal from a literary language to a mere patois, its employment in public documents being forbidden by a decree of François I. in 1527. But though the modern Gascon and Languedocian dialects are but wrecks of the old 'doux parler' of the South, Provençal has left in French many traces of its influence in the shape of some fifty seafaring and miscellaneous terms—*aulan*, *mistral*, *corsaire*, *ballade*, *croisade*, &c. There are Provençal dictionaries by Raynouard (6 vols. Par. 1838-44) and Honnorat (3 vols. Digne, 1846-47), and Diez gives a masterly sketch of the grammar in his *Grammatik der Romanischen Sprachen* (4th ed. 3 vols. Bonn, 1876). See also P. Barbe, *La Vérité sur la Langue d'Oc* (2 vols. Toul. 1873).

Provençal literature consists exclusively of poetry, and this poetry is chiefly lyrical in character. Of the popular epic no traces survive, if indeed they ever existed; and the fragment *Plamenca*, which Hueffer styles an 'artistic epic,' is simply a metrical romance like the *Fierabras* or *Goffroy de Brunissende* of Borneilh. The favourite forms of composition with the Troubadours (q. v.) were the amorous *Canzo*, marked by a slavish regularity of rhyme and pause; the freer *Sirventés* or 'service-lay,' employed for eulogies or satires; the sonnet, like Petrarch's, of fourteen lines; the *Tenson*, or amœbæan strain; the *Planh* or 'plaint,' and *Frottola*, a forerunner of Tupper's *Philosophy*; and a species of macaronic verse, whose invention was ascribed to Raymond de Vaquieras, where the first stanza might be in Provençal, the next in Tuscan, the third in French, the fourth in Gascon, the fifth in Catalan, and the sixth and last in all five languages together. But if the forms of Troubadour poetry were manifold, its themes were singularly few. Love was the one absorbing subject alike of *Canzo* and *Tenson*, if love may be called that shallow wantonness which only deepened into crime, and oftener when repulsed sought for itself another and an easier course. From the Arabs, with whom Provence was brought in contact by its fusion with Catalonia in 1092, the poets of the South derived their voluptuous chivalry and courteous contempt of womankind. Doubtless to them Guillem de Poitou, the earliest of the Troubadours, refers in his poems (circa 1095), as his masters in the poetic art; for only thus can we explain the artificial character of all Provençal literature, which with its thou-

sand repetitions and wearisome extravagances reads like a bundle of old valentines; exquisitely harmonious, it may be, but stale and pointless save to the ears to whom they were first addressed. Love was the prompting spirit of the very satires, most of them being aimed at scornful fair ones or successful rivals. They were rarely levelled by Churchmen against heretics, or by heretics against the Church; more rarely still against all sorts and conditions of men, like the famous *Sirventés*, ascribed to Folquet de Lunel, which roundly abuses emperors, kings, nobles, farmers, and peasants, popes, monks, and heretics, innkeepers and usurers, with all and every one besides. We say 'ascribed,' because our knowledge of the Troubadours, based chiefly on the naïve *Vies des plus Célèbres et Anciens Poètes Provençaux* (Lyon, 1575) of Nostradamus, brother of the astrologer, is vague in the extreme. Common consent, however, ranks the following as the best:—Bernard de Ventadour (12th c.), the grace and melody of whose fifty surviving *Canzos* bear out the eulogy pronounced on them by Petrarch in the fourth canto of his *Trionfo*; Arnould Daniel (12th c.), who, says Dante (*Par.* c. 26), 'in love ditties and the tales of prose without a rival stands.' He was the reputed inventor of the *sestine* or six-lined stanza, and Tasso attributes to him the epic romance of *Lancelot of the Lake*, only preserved to us in the German translation of the minnesinger Ulrich von Zazichoven; Gaucelm Faidit (12th c.), of whom we have sixty pieces, besides a satirical play against Rome, acted at the court of the Marquis of Montferrat between the years 1193-96; Jaufre Rudel (12th c.), 'the songster of Toulouse' (*Par.* c. 26), who, in his own words, 'loved a stranger to his eyes,' the Countess of Tripoli, at sight of whom he died; Bertrand de Born (1145-1215), author of warlike *Sirventés* and glowing songs of love, the evil counsellor of John of England, whom Dante saw in hell bearing his severed head lanternwise (*Inf.* c. 28); Giraud de Borneilh (1160-1219), of whose *Canzos*, which gained him the title of 'Master of the Troubadours,' no less than eighty-two have been preserved; Peire Vidal (died 1229), whose mad adventures as a gallant and crusader rang through all Europe, and who died in a madhouse, leaving some sixty compositions, amongst them a treatise on the art, to him unknown, of holding the tongue; Folquet de Marseille (1160-1231), who from a profligate became a monk, and is said to have been Bishop of Toulouse and De Montfort's ally in the Albigensian Crusade. Dante calls him the 'jewel, lustrous and costly, that great renown hath left, and not to perish ere these hundred years five times absolve their round' (*Par.* c. ix.); Peire Cardinal (13th c.), author of seventy poems, remarkable for the variety of their rhythms and their fierce invectives against parvenus, dissolute priests, and *femmes galantes*; and lastly, Giraud Riquier, whose ninety pieces include a pastoral, a sonnet to the Virgin, and a supplication to Alfonso X. of Castile praying that the jongleur of a troubadour might in some way be distinguished from jongleurs exhibiting learned pigs. As in old fairy tales King Oberon's gallant courtiers change at the cockcrowning to withered leaves, so did the 'gay science' vanish suddenly before the inrush of a stern outer world on the earthly paradise of Provence. The *Noels Provençaux* (Avis. 1669) of the clerkly Nicolas Saboly were almost the sole productions of the Provençal lyre from the 14th c. down to our own day. Recently there has arisen a little band of poets headed by Jasmin, the 'barber of Agen' (1798-1864), who have essayed once more to touch its long-hushed strings. But though Jasmin's *Papillotes* (Par. 1860) and Mistral's *Calendau* (Avis. 1867) are popular amongst their authors' countrymen, they are none the less anachronisms, impotent to arrest the forces which have rendered French the language of culture and progress throughout the length and breadth of France. See Diez, *Leben und Werke der Troubadours* (Zwick. 1827), and *Die Poesie der Troubadours* (Zwick. 1827); Fauriel, *Histoire de la Poesie Provençale* (3 vols. Par. 1846); Mila y Fontanals, *De los Trovadores en España* (Barc. 1861); J. Kutherford, *The Troubadours* (Lond. 1873); C. Bartsch, *Chrestomathie Provençale, accompagnée d'une Grammaire et d'un Glossaire* (3d ed. Elberf. 1874); Saint-René Taillandier, *Les Destinées de la Nouvelle Poesie Provençale*, in the *Revue des Deux-Mondes* for December 1875; F. Hueffer, *The Troubadours, a History of Provençal Life and Literature in the Middle Ages* (Lond. 1878); and A. Birch-Hirschfeld, *Ueber die den Provenzalischen Troubadours der 12 und 13 Jahrhunderten bekannten epischen Stoffe* (Halle, 1878).

* Such are the etymologies accepted by Diez and Brachet, though Grimm derives *oc* (Old Fr. *o*) from the Ger. *ja*, and compares *oïl* with the M. H. Ger. *ja* *er*.

Proverbs (Lat. *pro*, 'for,' and *verbum*, 'a word,' because a general employed for an individual word) are defined in *Don Quixote*, part i. c. 39, as 'short sentences drawn from long experience,' and discover, according to Lord Bacon, 'the genius, wit, and spirit of a nation.' They constitute four of the books of the Old Testament, were cited by Christ himself (Luke iv. 23, 24; John iv. 37), furnish titles to three of Shakespeare's plays, and are sown broadcast through the writings of Plautus, Rabelais, Montaigne, Cervantes, Fuller, Butler, &c. Their essential notes have been shrewdly declared by Howell to be 'shortness, sense, and wit,' to which Trench adds popularity as the most essential of all, comparing aphorisms that have not yet acquired a recognised currency and value to the rude unstamped ore newly dug from the mine. But there is hardly any race so mean or household so small as not to have its own peculiar P., so that popularity becomes a question of degree; and a truer simile would be that of coin newly struck, but for all that coin. Or, in other words, some P. may have a universal currency; others, like the old trade tokens, may be valueless beyond a circumscribed area. Frequent though accidental attributes of P. are their employment of the concrete for the abstract, e.g., 'The wine-cup drowns more than the ocean,' for 'More men die by intemperance than by drowning;' rhyme, as the Greek '*Pathēmata mathēmata*' (Herod. i. 207), or 'No pains, no gains;' alliteration, as 'Out of debt, out of danger,' or the Italian '*Traduttori traditori*;' and hyperbole, as when, to express a man's unvarying good luck, the Arabs say, 'Fling him into the Nile, and he comes up with a fish in his mouth.' A striking feature of P. is their indefinable antiquity. Only in rare instances can we point to the circumstances attendant on their birth, as in the case of 'Is Saul also among the prophets' (1 Sam. x. 10-12), or 'One butcher fears not many sheep,' first uttered by Alexander when timid officers described the vastness of the Persian host. And of the few similar records that have come down to us, the majority, perhaps, are mere eponymous fictions. 'Many P.,' says Max Müller, 'are chips of mythology, e.g., the German "*Morgenstunde hat Gold im Munde*;"' and many P. that might appear a growth of yesterday are to be met with in ancient writers. Thus, our 'Liars should have good memories' is St. Jerome's '*Mendaces memores esse oportet*;' in '*Si quis dat munnos ne quare in dentibus annos*' we recognise our own 'gift horse;' and the saws concerning 'hungry bellies,' 'a bird in the hand,' 'a rolling stone,' with scores of others, have likewise figured in a classic or mediæval garb. Where, however, the same idea is conveyed by the P. of different nations under different forms, it is difficult—often impossible—to determine whether it was struck out independently, or whether one nation has borrowed it from the other. We feel at once that a common conception underlies the Greek 'Owls to Athens,' the Rabbinical 'Enchantments to Egypt,' the Eastern 'Pepper to Hindustan,' the mediæval 'Indulgences to Rome,' and our own 'Coals to Newcastle;' but it would be rash to affirm that the English proverb was consciously copied from the Greek, because each so unmistakably bears its special local imprint. Frequently, indeed, the nationality of a proverb may be decided on internal evidence. 'When thy house is on fire, warm thy hands at the blaze' presents an admirable picture of Spanish dignity: 'Revenge is a morsel for God' is plainly a countryman of Machiavel; none but Eastern slaves could have enunciated 'When the monkey reigns, dance before him,' or 'Kiss the hand that thou canst not bite;' whilst 'A hedgehog will open when he is wet' is the formula by which the hedgehog-eating Gipsy expresses the truth '*In vino veritas*.' The number of P., and the estimation in which they are held, vary greatly with different races and times. Trench rates the entire stock of Spanish P. at 'the almost incredible number of from five and twenty to thirty thousand,' but this number is far exceeded by the P. of Germany, amounting, according to Wander, to some 145,000, whilst the prominent part these play in *bauer* philosophy has been charmingly illustrated by Auerbach in his *Dorfgeschichten*. Classical P. have been collected by Polydore Virgil (Ven. 1498), Erasmus (Par. 1508), Leutsch and Schneidewin (2 vols. Gött. 1839-51), and Kruse (1863); Arabic by Freytag (3 vols. Bonn, 1838-43); Finnish by Lönnrot (Hels. 1842); Dutch by Harrebomée (3 vols. Utr. 1858-65); French by De Lincy (2d ed. 2 vols. Par. 1859) and Cahier (Par. 1856); English by Bohn (Lond. 1855) and Hazlitt (Lond. 1869); Scotch by A. Hishop (Edin. 1870); and German by Wander (5 vols.

Leips. 1863-77), whose work, by far the ablest and most exhaustive that has yet appeared, compares with the P. of Germany those of England, Denmark, Bohemia, France, &c. See Duplessis, *Bibliographie parémiologique* (Par. 1847); Zacher, *Die Deutschen Sprichwörter-sammlungen* (Leips. 1852); Quillard, *Études historiques, littéraires et morales sur les Proverbes Français* (Par. 1860); Trench, *Lessons in P.* (6th ed. Lond. 1869); Sterling, *Literature of P.* (Lond. 1860); and Kelly, *P. of all Nations* (3d ed. Lond. 1870).

Proverbs, Book of, bears a superscription ascribing it to Solomon, king of Israel. 1 Kings iv. 29-34 shows that Solomon was famous as a composer of the maxims or aphoristic sentences of which Orientals have always been fond, and renders it probable that many of his sayings have been preserved in this book. But that the whole book was not composed by him is proved by statements in itself, and by the superscriptions of the several parts. It is believed by critics that the original portion of the book, in which are many genuine proverbs of Solomon, is chap. x. 1-xxii. 16, to which chap. xxv.-xxix., till then floating in oral tradition as proverbs of Solomon, was added in the time of Hezekiah (cf. xxv. 1). It is doubtful whether the portions xxii. 17-xxiv. 22, and xxiv. 23-34, belonged to the original work or were added at this time. Chap. xxx.-xxxii. was probably added at a later time, as also i.-ix., which is an introduction to the whole collection, probably composed by the last editor. See Bleek's *Einleitung in der A. T.* (Eng. trans. 1869).

Providence is the name given to the order of nature in reference to the provision made beforehand for the existence and well-being of all living creatures, especially mankind. In a wider sense P. is made to refer also to inanimate nature, and is sometimes used as a synonym for God.

Providence, the second city of New England, U.S., the seaport and one of the capitals of Rhode Island, is at the head of navigation on Narragansett Bay, 178 miles by rail N.E. of New York, and 44 S.S.W. of Boston. P. occupies 14½ sq. miles on both sides of the river, which in the geographical centre of the city expands into the ellipse-shaped 'Cove,' a mile in circumference, and surrounded by a park of fine shady trees. P. has 80 churches, among them one built in 1638 by Roger Williams, the oldest Baptist church in America. There are also Rhode Island Hospital, Butler Hospital for the insane, with many other hospitals and asylums, 12 state banks, 25 national banks, 9 savings banks, 1 high school, 11 grammar, 31 intermediate, and 36 primary schools; Brown University, a Baptist Institution with 16 professors and over 250 students, and a library of 45,000 volumes; a large and well-endowed boarding-school of the Society of Friends, with about 200 pupils; the Athenæum, with a library of 35,100 vols.; 18 insurance companies, several railways meeting in one central station, several lines of steamboats, a state prison, county jail, and reform school. The Butler Exchange, the Arcade, the State House, and the Narragansett Hotel are fine buildings; and P. is famous for its many beautiful private residences surrounded by extensive grounds. P. is the centre of a large manufacturing district, and has great trade, especially in cloths, chemicals, dye-stuffs, and coal; of print cloth alone in 1875, 3,324,780 pieces of 40 yards each were sold. The iron manufacture is also large, there being 26 works for engines, boilers, locomotives, &c., and 3 screw factories. There are 86 jewellery and silverware factories. P. has four daily, one semi-weekly, six weekly, and two monthly newspapers. Pop. (1875) 100,675.

Provincial of a monastic order is the superior of the abbots, priors, or other superiors of the religious houses in a province, corresponding to a Metropolitan (q. v.) among the secular clergy.

Proving the Tenor. In Scotland, the terms of a deed lost or destroyed may be proved before the Court of Session by an action of P. the T.

Provins, a town in the N.E. of France, department of Seine-et-Marne, 29 miles E. by N. of Melun, is situated on the Durelin and the Voulzie, which turn some fifty or sixty corn-mills in the district. P. is surrounded by ancient fortifications, and is divided into two parts. The upper town contains the Tour de César of the 15th c., and the church of Saint-Quirice of the 12th c. In the lower town is

the church of Sainte-Croix, and dating from the 13th c., the cloister of the convent of the Grey Friars, and the Grange-aux-Dîmes. P. is famous for its roses. Pop. (1872) 7596.

Provost (Old Fr. *prevost*, Lat. *præpositum*, 'one placed over') is in England the chief dignitary of a cathedral or collegiate church, ranking next after the archbishop or bishop. The heads of Eton College and Kings College, Cambridge, are also provosts. In Scotland, a P. is the chief magistrate of a royal burgh, the title corresponding to the English *mayor*. The provosts of Edinburgh and of Glasgow are styled 'Lord P.' In a written address, the Lord P. of Edinburgh is entitled to have 'The Right Honourable' prefixed to his Christian name. The Lord P. of Glasgow is styled 'The Honourable the Lord P.'

Provost-Marshal, in the navy, is an officer who has charge of prisoners taken at sea, and of a prisoner before a court-martial. In the army, the P.-M. is an officer whose duties are to see to the maintenance of military discipline, to seize and secure deserters and other criminals, to preside over and enforce their punishment, and to check marauding.

Prox'y (cont. from obsolete Eng. *Procuracy*), the name given to the agency by which one person may lawfully act or vote for another in his absence. Every member of the English House of Lords possesses this power, but no peer can hold more than two proxies, nor use them either in judicial cases or when the House is in committee.

Prudentius, Aurelius Clemens, a Christian poet, born 348 A.D., was successively a pleader, judge, and soldier under more than one Roman emperor. What we know of P. is derived exclusively from a short autobiography in verse written by the poet at the age of fifty-seven, and designed as an introduction or preface to his writings, of which it contains a catalogue. From this we learn that P. was born in the reign of Constantius II. and Constans. After receiving a liberal education he frequented the schools of the rhetoricians, led a gay life, practised as a forensic pleader, discharged the duties of a civil and criminal judge, and obtained from the Emperor—whether Theodosius or Honorius is uncertain—a military appointment at court, which placed him in a position next to royalty. Eventually P. became tired of earthly pomp, sensible of the emptiness of human honours and display, and earnest in the cause of the Christian religion. We hear nothing of him after 405 A.D., but the year of his death is not known. His principal extant writings, all of a devout character, and in a great variety of metres, are:—(1) *Præfatio*, autobiography and catalogue of works; (2) *Cathermerinon Liber*, twelve hymns proper to be said or sung by the sincere Christian; (3) *Apotheosis*, on the divinity of our Saviour, and his relation to the Father; (4) *Hamartigenia*, on the origin of sin; (5) *Psychomachia*, the conflict of virtue in the soul of the Christian; (6) *Contra Symmachum, Lib. I.*, on the worthlessness of the heathen gods, with an account of the conversion of Rome to Christianity; (7) *Contra Symmachum, Lib. II.*, a refutation of the arguments in the petition of Symmachus to Valentinian, praying for the restoration of the altar and statue of Victory cast down by Gratian; (8) *Peristephanon Liber*, fourteen poems in honour of saints, mainly Spanish, who had won the martyr's crown; (9) *Diptychon*, on remarkable characters and events in Bible history, a series of forty-eight poems of four verses each; (10) *Epilogus*, consisting of thirty-four lines, apparently written after P. had withdrawn from public life. The style of P. is confessedly impure, his prosody faulty, his themes destitute of creative power; yet he was immensely popular in the Middle Ages. This is easily understood, but how Bentley, a scholar and critic of great acumen, should have styled him 'the Horace and Virgil of the Christians' is not so clear. The *editio princeps* of P. was printed at Deventer in 1472.

Prud'hommes, Conseils de, tribunals for arbitration in trade disputes, existed at Marseille in 1452, and at Lyon in 1464, and were re-established in the latter city (1806) and in Paris (1844). They are now regulated by the decrees of May 27, 1848, and March 2, 1852, are composed of workmen elected by masters and masters by workmen, and have the power of inflicting small pecuniary fines and short terms of imprisonment, their jurisdiction being restricted to cases where the sum at issue does not exceed 200 francs.

Prunell'a, the scientific name of a genus of small hairy perennial herbs, with whorled flowers in dense terminal heads, belonging to the natural order *Labiatae*, and found in the temperate regions of both hemispheres. *P. vulgaris*, which occurs in the four continents, as also in Australia, is a very common British plant of pastures and waste places. Formerly it was in sufficiently high repute to obtain its existing popular name of 'self-heal';—no surgeon was wanted when it could be made use of: it still holds a place amongst rustic herb-medicines.

Prunes. The ordinary kind of P. of grocers' shops are the fruit of the St. Julian variety of the common Plum (q. v.), dried either by exposure to the sun, or by artificial means, or by these processes alternately. For their production, the tree is largely grown in France. In some districts P. are still much used stewed, or in pies or puddings. Medicinally, P. are a mild laxative; they are also one of the ingredients of *confectio semine*. The best dessert P. or 'French plums' are carefully prepared from the yellow fruits of a variety called the Brignole plum; they come from Provence. In Germany the Zwetschen variety is cultivated to supply P.

Pruning consists in depriving a plant of a portion of its stem, branches, buds, leaves, bark, or roots in order to produce particular effects on the remaining part of the plant. There are different kinds of P., named after the manner, extent, and implement used, such as lopping, clipping, knife-pruning, disbudding, disleafing, disbarking, &c. The object is to concentrate the action of the sap for the benefit of the part that is left, and to give a stimulus to vitality. The amount of P. must be determined by the exigencies of each particular case and the judgment of the operator, it being borne in mind that P., not mutilation, is in all cases the object to be attained—conservative surgery, not reckless hacking. For forest-trees P. is of the greatest use in modifying the quantity of timber produced. For ornamental trees it is chiefly employed to remove diseased branches, because much of the effect of these trees depends on the development of their natural form and character. For ornamental shrubs it cannot be dispensed with, since many of them are grown for their flowers, which are produced much stronger and of brighter colours when shoots are thinned out, or shortened, or both. In fruit-trees and shrubs, P. is by far the most important part of their cultivation, and if unattended to, the shoots and fruit would gradually diminish in size, and the produce, though numerous, would be deficient in succulence and flavour. Such we find to be the case in neglected orchards. The application varies according to the species. Herbaceous plants are often pruned, both roots and branches, when transplanted. Root-pruning is performed to check the formation of wood-shoots, and induce the formation of bud-shoots. It is chiefly employed to check the luxuriance of young fruit-trees and throw them into blossom. Clipping is principally applied to hedges, and to dwarf shrubs used for borders of garden walks. Thinning is performed when plants stand too close together, or when branches, leaves, flowers, or fruit, are too numerous on an individual plant to be properly nourished, and to receive due exposure to sun and air. Coppice-woods consist of trees and shrubs cut down periodically, their stems and branches thus being constantly renewed.

Seasons for P. vary according to the object in view. The worst season is the spring, just before the expansion of the leaves, as at that time the sap is rising with the greatest vigour.

Pru'nus. See PLUM.

Pruri'go is a chronic papular affection of the skin, the most prominent symptom of which is intense itching. The skin is thickened and discoloured, and the eruption of isolated and scattered papulæ does not differ in colour from the general surface. P. is unaccompanied by constitutional symptoms. There are three principal varieties of P., viz., *P. mitis*, *P. formicans*, and *P. semilis*. *P. mitis* makes its appearance in the spring and summer months, without premonitory symptoms, and generally declines at the end of two or three weeks; but it may be prolonged for several months. In *P. formicans*, the itching is incessant, frequently insupportable, and is compared by patients to the piercing of the skin with red-hot needles, or to having the flesh devoured by thousands of ants. *P. semilis* is similar, but the disorganisation of the skin is more complete.

In the treatment of P., great attention should be paid to diet, and improper and over-stimulating diet and stimulating drinks

should be avoided. Baths, at a temperature not higher than 70° Fah., consisting of simple water and soap, or the alkaline or sulphur bath, should be daily used; and the cold-water bath and sea-bathing may be found useful. Mercurial lotions and ointments, or lotions of sulphuret of potassium, and prussic acid lotions have the greatest reputation. The greatest attention should also be paid to personal cleanliness.

Prussia (Ger. *Preussen*, a name derived from that of the old Slavic *Pruszi*), by far the largest and most powerful kingdom of the German Empire, of which it is the dynastic and military head, extends in lat. 49° 8'–55° 50' N., and long. 6°–22° 50' E. Its extreme length from N.E. to S.W. is 720 miles, while its breadth from N. to S. varies from 180 to 470 miles. Including Schleswig-Holstein, it is bounded N. by the German Ocean, Denmark, and the Baltic, E. by Russia, S. by Austria (Galicia, Schlesien, Mähren, and Böhmen, by Sachsen, by the Thuringian states of Bayern, Hessen-Darmstadt, and Elsass-Lothringen, and W. by Luxemburg, Belgium, and the Netherlands. Outlying parts of P. are Hohenzollern (q. v.), encircled by Württemberg and Baden, and the Jahdegebiet, at the mouth of the Jahde, surrounded by Oldenburg, to landwards. The Jahdegebiet was purchased in 1853, with a view to the establishment of the naval station of Wilhelmshafen. A somewhat complex appearance is given to the map of P. by the number of minor states and their sub-sections included within its political outline. Of these, the chief are the grand duchies of Mecklenburg and Oldenburg, the district of Hamburg, the duchies of Braunschweig and Anhalt (in eight sections each), the province of Upper Hessen, and the principalities of Waldeck, Pyrmont, Lippe-Detmold, and Schaumburg-Lippe. P. has over 1000 miles of coast-line, of which three-fourths are on the Baltic. The N. Sea coast is indented by the estuary of the Elbe and the inlets which receive the Ems, the Weser, and Jahde; the Baltic coast by the fjords on the E. side of Schleswig, the Gulf of Lübeck, the Kleine and Grosse Haff at the mouth of the Oder, the Gulf of Danzig (including the Frische Haff), and in the extreme N.E. by the Kurische Haff. To P. belong the E. and N. Frisian Islands, and, in the Baltic, Alsen, Fehmarn, Rügen, Usedom, and Wollin. P. is divided into eleven provinces (subdivided, again, into thirty-five *Regierungsbezirke* or administrative districts), of which the areas and populations are as follows, according to the census of 1st December 1875:—

Provinces.	Area in sq. miles.	Pop. 1875.	Chief towns.
Preussen (proper).	24,123	3,199,171	Königsberg.
Brandenburg . . .	15,565	3,126,425	Berlin.
Pommern	11,527	1,462,290	Stettin.
Posen	11,126	1,606,084	Posen.
Schlesien	15,556	3,843,699	Breslau.
Sachsen	9,745	2,169,031	Magdeburg.
Schleswig-Holstein	7,218	1,074,085	Schleswig.
Hannover	14,855	2,017,393	Hannover.
Westfalen	7,799	1,905,697	Münster.
Hessen-Nassau . . .	5,943	1,407,898	Kassel.
Rheinland	10,415	3,804,257	Köln.
Hohenzollern . . .	439	66,466	Hechingen.
	134,411	25,742,496	

The former duchy of Lauenburg, united since 1865 to P. by *personal union*, was formally annexed to the province of Schleswig-Holstein in 1876. Berlin is the capital of both the Prussian kingdom and the German Empire.

Physical Aspect.—P. may be divided into two sections, corresponding to the well-marked physical character of two great sections of the country. (1) The greater part of P., comprising portions of Hannover, Schleswig-Holstein, part of Sachsen, Brandenburg, Pommern, Posen, Schlesien, and E. and W. Preussen, belongs to the sterile plain of N. Europe, which extends E. and W. from Russia to the Netherlands. This flat region has a loose, sandy soil, and is strewn with erratic boulders of granite. Except in the more favoured districts, or along the green river-margins, the surface defies cultivation, and is in great part occupied by heath and morass, while the open sand-flats show here and there thin belts of stunted pine. In some districts the roads are lined by straggling rows of plum and poplar trees. E. of the Elbe small lakes are very numerous, especially in E. Preussen, where the surface rises considerably. The coast, like that of Holland, is defended from the sea by dykes, and many of the rivers, such as the Vistula and Niemen, are in great part lined

with embankments. The *haffs* ('bays') of the Baltic are lagoons formed at the mouths of rivers by islands or sand-spits. Having a slight northward slope, the great plain is traversed by several large navigable rivers—the Elbe, the Oder, with its great affluent the Warthe, the Vistula, which has a course of 160 miles in W. Preussen, and the Niemen, in the extreme N. of E. Preussen, through which it flows for 70 miles. Minor streams are the Pregel, the Weser, and the Ems, the last being the only river of any size entirely within Prussian territory. The northern plain is separated on the S. from Böhmen by the Riesengebirge (q. v.), and from Sachsen and several minor German states by the Thüringerwald. To the N. of Thüringia, and standing well within the limits of the great plain, are the Harz Mountains (q. v.) of Hannover. Further W. the Teutoburgerwald extends between the Weser and Ems. (2) The S.W. part of P., including Westfalen, Rheinland, and Hessen-Nassau, differs from the rest of the country, for the plain here swells into uplands, intersected by bold mountain ranges. Along both banks of the Rhine there are narrow strips of level land, hemmed in on the W. by the Vosges or Hardt Mountains, and on the E. by the Westerwald, Taunus, &c. The scenery of the Rhine valley from Bonn upwards as far as Prussian territory extends, is singularly picturesque. Vines clothe the banks and climb the hillsides, which are often terraced for their support, while romantic strongholds crown the most commanding positions.

Climate, Botany, and Agriculture.—The great plain, more especially in the E., is exposed alternately to hot summers, accompanied by severe droughts, and to rigorous winters. The winters are less severe as we advance from E. to W., and the rainfall is correspondingly greater. The mean annual temperature at Königsberg is 43° F., at Berlin 46° 5, and at Hannover 48°. The Rheinland is the most northerly wine district in Europe. Its wines are acidulous, because of the want of heat to develop the saccharine matter in the grape. The clusters, however, are mellowed by the first frosts of the Rhine winter, which is so severe that the navigation of the river is suspended for a time almost every winter because of floating ice. In 1875 the forests throughout P. covered an area of 19,889,300 acres (those belonging to the state 5,752,180 acres in extent, yielding to the revenue £2,750,000 in the year ending March 1878.) The chief trees are pines, firs, beeches, alders, birches, and oaks, and the most thickly wooded parts are in the districts of Arnberg, Koblenz, Wiesbaden, Kassel, Frankfurt, and Liegnitz. Much of the most productive and best cultivated land in the Empire belongs to P., the area of which in 1875 comprised 50·1 per cent. of land under grain and fruit crops, and 18·3 per cent. of meadow and pasture. In 1877 the state domains had an area of 856,893 acres, and yielded a revenue of £1,071,190. The state, by the abrogation of land-taxes, the encouragement of special schools, &c., has greatly advanced the condition of agriculture and improved the position of the agriculturists, who number about one half of the inhabitants. Perhaps the most thoroughly cultivated part of P. is Schleswig-Holstein, which has 64·1 per cent of its area under the plough. Other highly cultivated districts are to be found in Sachsen, Posen, Pommern, and the Rheinland. Of the common crops, the proportion of rye is 24 per cent., of oats 16, of potatoes 12, of wheat 10, and of barley 8. Wheat is chiefly produced in Hannover and Schleswig-Holstein, along the lower courses of the Oder, Vistula, and Warthe, and in the fertile district of Magdeburg. Oats and barley are the principal crops in the bleak, sandy, eastern provinces. Flax and hemp are great staples, while minor crops are buckwheat, oil-seeds, woad, and safflower. Chicory is extensively grown; also beetroot for the manufacture of sugar, particularly around Magdeburg. The yield of tobacco, which is chiefly produced around Potsdam, and in Posen, Sachsen, Hannover, and Rheinland, amounted in 1874 to 65,697 tons. Of the greatest importance is the wine-culture, mainly carried on along the banks of the Rhine (see RHINE WINE). Throughout P. the yield of wine in 1874 amounted to 441,056 gallons.

Zoology, Live Stock, &c.—The larger wild animals, including the bear, stag, fallow-deer, boar, wolf, and lynx, are confined to the remoter highlands, while among the common animals of lesser size are otters, beavers, badgers, foxes, martins, and weasels. Game is abundant; pheasants and partridges are especially plentiful in Schlesien, while the marshes of Pommern and W. Preussen literally swarm with wild geese. P. is unsurpassed by any country for the rearing of horses, the excellence

of its breeds being in great part due to the organisation of the royal studs, of which there are fourteen, including the three principal studs at Trakehnen, Neustadt, and Graditz. In 1873 there were in the whole monarchy (including the army) 2,278,724 horses. The finest cattle are bred along the marshy coast of the North Sea, where there is plenty of luxuriant pasture. The total head of cattle in P. was 8,612,150 in 1873. In 1873, out of a total of 19,624,758 sheep, as many as 8,160,189 were merinos. Pommern is the chief sheep-farming province. Sachsen, Hessen-Nassau, Rheinland, and Westfalen are noted for their swine (of which Saxony bred 4,278,531 in 1873) and goats. Honey and wax are produced in large quantity in the heathy parts of Hannover, Brandenburg, &c., while in the latter province some silk culture is carried on, the total produce in 1873 being 5046 lbs of cocoons. The sea-fisheries employed in 1872, in the Baltic, 9575 fishermen; in the North Sea, 1313 boats; and in the lagunes, 5042 fishermen. Sturgeon are caught in the Elbe and trout in the mountain streams, while the Oder abounds with eels.

Geology and Mineralogy.—The great plain mainly comprises Tertiary formations, supporting extensive layers of lignite (*braunkohle*), and mud and sand of recent date. In Rheinland occur Primary beds, while parts of Westfalen and Sachsen are covered with Oolitic formations, here and there erupted with igneous rocks. Schlesien, Westfalen, Rheinland, and Sachsen are the chief mining provinces, and the districts in these particularly distinguished for mineral wealth are Dortmund, Breslau, Klausenthal, and Halle. The most important minerals of P. are iron and true coal, and in 1876 there were 448 coal-pits in operation, employing 158,902 persons, and producing 43,364,968 tons, valued at £11,329,111, and 737 iron-mines, with 19,322 hands, the product of which amounted to 2,572,250 tons, value £867,336. In addition, 553 lignite mines yielded 8,985,122 tons, of the value of £1,574,985. The coal-pits in the Ruhr-Düsseldorf district, which extend over more than ten miles, supply nearly a half of the total produce, while those in the basin of the Sar, in the S.W. of Rheinland, furnish about a sixth. P. raises 93 per cent. of all the coal produced in Germany. Iron is found more or less in all the provinces except in Pommern and Schleswig-Holstein, and is most abundant in Westfalen, Rheinland (Koblenz and Düsseldorf), and Schlesien (Oppeln). P. stands among the first zinc-producing countries of the world, having 70 mines, the output of which amounted to £647,760 in 1876. In the same year, the produce of other minerals was:—lead, £1,005,195; copper, £347,246; salt, £306,252. Among the minor minerals found are cobalt, antimony, manganese, arsenic, sulphur, alum, nickel, plumbago, gypsum, petroleum, jasper, onyx, and amber. Silver and gold are procured in small quantities in conjunction with other metals. Freestone and slate are widely distributed; marble is quarried in Schlesien and Westfalen; and mill-stones are procured along the Rhine. In 1876 the state had 17 mines for coal, 12 for lignite, 19 for ironstone, 12 for lead, silver, and copper, &c. The more celebrated of the many mineral springs of P. are those of Aachen, Ems, Wiesbaden, and Selters.

Industries, Commerce, &c.—The great industrial centres of P. are in Ober Schlesien, Westfalen, and Rheinland, all in proximity to the rich coal and iron deposits. After these in importance come Brandenburg, Sachsen, and Hessen-Nassau. In 1876 there were in P. (principally in the provinces named) as many as 1074 smelting works and furnaces, which employed 121,792 men and produced 3,268,367 tons (value £29,219,756). Cast and wrought iron alone was manufactured to the value of £19,931,598, and this special industry employed 87,989 men. The iron industries are the most important, and are carried on most extensively in the districts of Oppeln, Frier, Düsseldorf, Aachen, and Arnsberg. Essen (q. v.), in the district of Düsseldorf, is the seat of the Krupp's vast steel works, while Witten, Bochum, and Spandau, are also noted for the production of steel ordnance. Machinery and locomotives are manufactured extensively at Königsberg, Elbing, Stettin, Berlin, Hannover, and Kassel; scientific instruments at Berlin, Kassel, Aachen, Bielefeld, Bonn, &c.; musical instruments at Berlin, Breslau, and Kassel; gold and silver wares at Berlin, Hemeilingen, and Hanau. Of the woollen manufactures of Germany, P. produces 65 per cent.; while of 458,000 looms for the manufacture of linen throughout the whole empire, as many as 250,000 belong to P. Fancy wools are a specialty of Berlin, which is also noted for its carpets and shawls. The district of Düsseldorf (including Barmen, Elberfeld, &c.), Münster, Liegnitz,

Erfurt, and the province of Hannover, are remarkable for the extent of their cotton and silk manufactures. In 1873 P. had 221 paper-mills, mostly in Rheinland, Westfalen, Sachsen, and Schlesien. In 1874, 337 mills produced 291,041 tons of beet-sugar, and 10,412 breweries 14,241,024 hogsheads of beer; while the total yield of spirits was 3,558,472 hogsheads. Other important manufactures are wine, leather, tobacco, and cigars, porcelain, glass, fancy goods, and articles in vulcanite. The chief shipbuilding ports are Kiel, Stettin, and Danzig. P. carries on direct trade with foreign countries mainly through the Baltic ports, but a large amount of trade passes through Hamburg and Bremen, and by rail through the Netherlands. In 1876 P. had in the mercantile service 3254 sailing vessels of 504,145 tons, with a personnel of 19,703, and 130 steamers of 28,539 tons, with a personnel of 1605. There entered the ports in 1875 with cargo, 26,370 vessels of 2,734,833 tons, and in ballast, 8624 of 611,093 tons; and cleared with cargo, 22,736 of 213,649 tons, and in ballast, 10,366 of 10,504,43 tons. The official trade returns are included in those of Germany (q. v.). P. has a very extensive and complete railway system, the portions of which in Hannover and Hessen-Nassau belong entirely to the state. In 1877 the total length of the railways was 10,454 miles, those belonging to the state having a length of 2854 miles, and those owned by private companies but under state administration, 1223 miles.

Education and Culture.—An account of the Prussian educational system is given in the article GERMANY. Despite all that the state has done and is doing to spread and equalise education, the older eastern provinces, lagging behind the younger and more vigorous ones to westward, are accounted among the least enlightened parts of the empire. In 1875-76, out of 85,507 recruits, 2749, or 3.214 per cent., were unable to read or write. Of those raised in Posen the percentage of the totally uneducated was 13.972, in Preussen, 8.78, and in Schlesien, 3.35; while in Westfalen it was 1.056, in Pommern, 1.528, in Hannover, 0.84, Hessen-Nassau, 0.53, Sachsen, 0.322, Brandenburg, 0.66, Schleswig-Holstein, 0.26, and Rheinland, 0.74. In 1871 P. had 34,988 elementary schools, with 4,495,040 pupils and 17,264 teachers. In 1877 there were, for higher education, 228 gymnasia, 33 pro-gymnasia, 84 real schools, 90 Bürgerschulen, 215 higher girls' schools, 68 Protestant and 31 Catholic teachers' seminaries, 4 Jewish teachers' seminaries, 9 universities, the Academy at Münster, and the Lyceum at Braunsberg. In the summer semester of 1878 the nine universities, the Münster Academy, and the Braunsberg Lyceum had a staff of 906 teachers, of whom 470 were ordinary, 7 honorary, and 202 extraordinary professors, and 227 privat-docenten; while the matriculated students amounted to 8219, comprising 3636 in the faculty of philosophy, 2261 in law, 1349 in medicine, and 684 in Protestant and 289 in Catholic theology. The non-Prussian students numbered 1080. In 1878 the University of Berlin had 201 docenten (including 63 ordinary and 57 extraordinary professors, and 77 privat-docenten) and 2237 students. In 1874 the departmental schools of P. were 155 in number. The fine arts were represented by 3 royal musical institutes, 10 music conservatories, 4 art academies, and 3 drawing-schools. There were also 120 professional and technical schools, 15 schools for the blind, and 35 for deaf-mutes. The universities are rich in libraries and scientific collections, and the art-treasures of Berlin are of European fame. In 1874 P. had 809 newspapers. The political press is under a strict censorship, and in the years 1876-77 as many as 115 editors and publishers were brought before Berlin law courts for the propagation of socialist opinions.

Constitution, Government, and Finance.—According to the charter of 1850, P. is a constitutional and hereditary monarchy. The king is assisted by a council of ministers, and shares the legislative authority with a representative assembly, consisting of two chambers—(1) the Herrenhaus, or House of Lords, composed of certain princes and nobles, life peers named by the king, noblemen elected in the provinces by all landowners, and representatives of the universities, of towns with a pop. of above 50,000, and of various other interests; (2) the Abgeordnetenhaus, or Chamber of Deputies, comprising 433 representative members, elected indirectly by all Prussians above twenty-five years of age. Bismarck's Districts Administration Act of 1873 reformed the aristocratic rural economy of P., abolished the old feudal county assemblies, and conceded self-government and representative institutions to villages and rural circles. This measure, regarded

by many as revolutionary, was pressed by the Chancellor as necessary to the due amalgamation of P. with the new empire in temper and principles. The law code mainly in force in the eastern provinces is the *Landrecht für die Preussischen Staaten*, compiled under Friedrich the Great, and introduced in 1794. Old Polish, Swedish, and German law is still common in certain parts, while the Köln district is under the *Code Napoléon*. Over 125 magistral courts there are 12 provincial courts of appeal, and from these cases may be carried to the upper tribunal in Berlin, the supreme court of law. In 1878 the Budget gave the revenue and expenditure as each £32,581,920, and the total national debt was £52,927,523 on 31st March 1877.

Army and Navy.—The military organisation is described in the article GERMANY. In 1876 the Prussian army comprised 13,804 officers and 319,824 men, of whom 203,760 were infantry. The mobilisation of the reserves is possible in ten days' time. In point of fact, within twelve days of the declaration of war by France in 1870, the mass of the troops were conveyed to the Rhine. The Prussian navy is that of Germany (q. v.).

Religion and Ethnology.—The royal family of P. belongs to the Protestant faith, but Roman Catholic as well as Protestant clergy are in part maintained by the state. In 1875 there were in P. 16,636,990 members of the Evangelical State Church (64.64 per cent.). In the older provinces of P. the members of the State Church are formed by the compulsory fusion of Lutherans and Reformed effected by Friedrich Wilhelm IV.; they amount to 13,266,620. But in Hannover and other recently acquired parts the Lutherans (2,905,250) and Reformed (465,120), though embraced in the State Church, do not acknowledge the union. There were 8,625,840 Roman Catholics and Old Catholics (33.51 per cent.), besides 1450 Greek Catholic, and 4800 German and Christian Catholics (separatists from the Roman Catholic Church). Of Lutheran separatists there were 40,630; of Reformed separatists, 35,080; of Moravian Brethren, 3710; of Irvingites, 2620; of Baptists, 12,210; of Mennonites, 14,650; and of Jews, 339,790. The population of P. is somewhat rigidly divided into the three classes of the nobles, the burghers, and the peasants, the first embracing as many as 200,000 persons. Some seven-eighths of the inhabitants are Germans; the non-Germanic element amounts to 2,897,200 souls, of whom 146,800 are Lithuanians, 2,432,000 Poles, 50,000 Czechs, 83,000 Wends, 10,400 Walloons.

History.—The Baltic coast region, still known as *Preussen* (P. Proper), was from pre-historic times the home of the Borussi or Prussi, a 'strong-boned, iracund, herdsman and fisher people,' of the Lithuanian family. From a very early period P. was famed throughout the world for the amber of which it still possesses unequalled supplies. That the Prussians came into conflict with the Goths prior to the migration of the latter southwards is all that is known of the people till the 10th c., when various attempts were made by the kings of Poland and the Polish clergy to introduce Christianity. Dreading political annexation, the Prussians opposed all missionary enterprises, killed, among other preachers, St. Adalbert, Bishop of Prague (997), and latterly alarmed Poland by their fierce and frequent incursions. A long and uncertain struggle between the Poles and Prussians ended at last only in the appeal of Konrad, Duke of Masovia, for aid to the Teutonic order of the Knights of St. George. Hermann von Salza, general of the order, promptly acceded to the request, only stipulating that all lands conquered by the knights should fall to the order. Then ensued a steady, systematic war of conquest (1230-83), conducted with great military skill and courage, and far less than the usual cruelty, and ending in the complete subjugation of P. to the order's rule. The civilising influence of the knights was soon seen in the foundation of towns and schools, the erection of strongholds, the improvement of agriculture, and the extension of commerce. So highly was the possession of P. valued by the order, that in 1309 its headquarters were removed from Venice to the new palace of Marienburg, which still stands a memorial of artistic refinement and regal splendour. About the year 1400, the period of their greatest prosperity, the knights held sovereign sway over a kingdom extending far into Kurland and Livonia, and owned 55 walled cities (including several great commercial centres), 48 castles, and 19,000 villages, while their revenue amounted to the then vast sum of 800,000 Rhenish guilders (£65,000). But soon prosperity led to luxury and dissension among the knights, and in a single defeat at the hands of an allied Polish and Lithuanian force at Tannenberg

(1410) their independence was broken. An honourable peace secured by the brave general of the order was sacrificed by still further internecine strife, and in 1466 Ermland and the western portion of P. were ceded to Poland by the Treaty of Thorn, while the eastern territory was only retained in fealty. In this extremity the knightly commonwealth adopted the policy of strengthening itself by electing as master scions of powerful German dynasties, and in 1511 the choice fell on the Markgraf Albrecht (q. v.) of Brandenburg-Kulmbach, and nephew of the King of Poland, tracing his descent from the Franconian line of the Hohenzollern family. Albrecht, having refused to take the oath of allegiance, was at once attacked by the King of Poland, and on the conclusion of a truce (1521), hastening to Germany to invoke the aid of his kin, he failed in his immediate object, but returned with the gift of the Reformation doctrines. With the consent of several of the bishops, and to the joy of nobles and people, he proclaimed his acceptance of the new tenets, and when his religious order was dissolved in 1525, he was acknowledged hereditary duke of secularised P. His long reign was marked not only by wise legal and financial reforms, but by the publication of important translations, the inauguration of an educational system, and above all by the foundation of the famous university of Königsberg. He died in 1568, and was succeeded by his son, Albrecht Friedrich, who subsequently became insane. The dukedom remained under a regency till Albrecht's death in 1618, when his son-in-law, Johann Sigismund (q. v.), Elector of Brandenburg, after having held the regency for several years, took possession of Eastern P. (the western part still remaining a province of Poland), which from this time was always joined to the Mark of Brandenburg. The Hohenzollern family allowed the opportunity to slip of uniting the N. and S.W. of Germany (which also was almost wholly Protestant) in a powerful league, and in the later years of Johann Sigismund there broke forth (1618) the dreadful Thirty Years' War, 'from the effects of which Germany seems only now to be recovering herself.' Johann Sigismund's successor, Georg Wilhelm (1624-40), the first incompetent ruler in his family, was completely under the influence of Count Schwarzenberg, an extreme Papist, suspected of acting for Austria. In attempting to remain neutral at a time of fierce contention, he only exposed the country to the ravages of imperial and Swedish armies alternately, and the havoc begun by war was completed by pestilence. On the accession of Friedrich Wilhelm (q. v.), trade and commerce were annihilated, agriculture was at a standstill, towns stood in blackened ruins, and wide tracts of country were entirely destitute of inhabitants. But out of chaos and ruin, by stern adherence to a wise policy, the 'Great Elector' raised his country into the position of a great European power. Perceiving the danger of dependence on the empire, he quietly and quickly raised a small but efficient army, with which in many an arduous campaign he carved out for himself the reputation of a bold, brilliant, dexterous leader. By playing off Swedes against Poles, he rid his duchy of P. of its allegiance to Poland, and on the revocation of the Edict of Nantes, introduced into this part of his territory some 20,000 French refugees, and with them the germs of flourishing industries. He abandoned the old system of military levies in his own states, and though he raised an army of 40,000 men, was enabled by strict economy to spare the finances of the country. Pursuing his supreme object of state unity, he stamped out the beginnings of constitutional life both in Brandenburg and P. so effectively, that from his reign may be dated that absolutism which continued almost unbroken till the middle of the present century. At his death in 1686, he left to his son Friedrich a strongly organised state of 50,000 sq. miles, and a million and a half inhabitants. After much intrigue and bribery, P. was raised to the rank of a kingdom (1701) by the Emperor Leopold I., who thus procured the support of Friedrich's well-drilled battalions in his French wars. On the day of his coronation Friedrich I. established the famous order of the Black Eagle. Though he augmented P. by peaceable acquisition, he was a vain, pompous, extravagant, splendour-loving king, and strikingly contrasts with his son Friedrich Wilhelm I. (1713-40), who, harsh, tyrannical, arbitrary, given to outbursts of brutal rage, frugal even to parsimony, carrying his contempt of ceremony and display to learning and its professors, living in the plainest style, enjoying coarse practical jokes, and spending his evenings in his 'tobacco-college,' was still animated by a love of the *salus rei publicæ*, and of his 'Potsdam Guard,' a regiment of giants recruited (occa-

sionally by kidnapping) from all parts of Europe. This erratic ruler raised the army to 80,000 men, acquired the city of Stettin and part of Pommern from Sweden, encouraged immigration to such an extent as to increase the pop. to 900,000 (on an area of 5000 sq. miles), abolished for ever witchcraft trials, and left a treasure of nine million thalers (£1,350,000). Friedrich II. (q. v.), called Friedrich the Great, one of the most powerful of all European rulers, succeeded to this heritage, and after a long and eventful reign of a thoroughly despotic character, and throughout which the king displayed in singular union the highest qualities of the statesman and the general, P. was raised to the position of the rival of Austria in Germany, disputing with that power the sway over the minor states. The first Silesian War gained, and the second secured, to P. the whole of Upper and greater part of Lower Schlesien. In the Seven Years' War, Friedrich, with England for an ally, maintained his crown against the combined forces of Austria, France, Sweden, Russia, and Sachsen. He further extended his territory in the first partition of Poland by the addition of what was called West P., excluding the towns Thorn and Danzig. The vigour with which he carried on war was equalled by the zeal with which he strove to remove every vestige of its evil effects. The latter part of his life (1763-86) was spent in unremitting labours of peace—in aiding the ruined with gifts, stimulating immigration by bounties, simplifying and bringing jurisdiction within the reach of the poor, and by manifold ingenious schemes directing the energies of his people into new channels. His nephew and successor, Friedrich Wilhelm II. (1786-97), a weak king, acting under the dominion of favourites, joined Austria in the attempt to turn back the tide of the French Revolution, which ended in the disasters of Valmy and Jemappes; excited the jealousy of Austria by the acquisition of the larger part of Great Poland, with the cities Thorn and Stettin on the second partition of Poland (1793); and received New East P., with Warsaw, on the third partition (1795). Suspicious of the secret policy of Austria and Russia, he concluded the Treaty of Basel, by which France received all her possessions on the right bank of the Rhine. The gain of territory to P. during his reign was counterbalanced by the imposition of an enormous debt. P. temporised for selfish ends during the struggle with Napoleon, and Friedrich Wilhelm III. (q. v.) had the mortification of seeing his supremacy in N. Germany threatened by the institution of the Confederation of the Rhine (q. v.). Jealous of the independence of P., Napoleon forced Friedrich Wilhelm into the war which ended in the occupation of Berlin and the humiliating Peace of Tilsit (1807). By this treaty the better part of Prussian territory was lost, with no fewer than 5,000,000 subjects. The army was permanently reduced to 42,000 men, and the country saddled with an indemnity of 140,000,000 francs. But this bitter experience bore excellent fruits. Stein, one of the ablest of all statesmen, abolished serfdom, threw open civil offices to all classes, and induced the king to grant municipal rights to the towns. The school system was placed, mainly by the efforts of Wilhelm von Humboldt, on a basis which makes it even yet the envy of other nations. Under Gneisenau and Scharnhorst, the provision limiting the army was evaded by training bodies of men and disbanding them, while keeping the figure at 42,000 nominally. The *Tugendbund*, or League of Virtue, formed by men of all ranks, but especially by professors and students, stirred the people to the deliverance of the Fatherland. At last the struggle came, and the power of Napoleon was finally broken in the battle of Leipzig (1813). The Congress of Vienna gave to P., in addition to the territory lost at the Peace of Tilsit, the Grand Duchy of Posen, Swedish Pommern, the Duchies of Westfalen and Berg, and the country between Aachen and Mainz. The growth of a national sentiment, which showed itself in a fervent desire for unity and constitutional government, was strengthened by the war of freedom and the achievements of Germans in literature, art, and science. The Zollverein (q. v.) brought P. into closer commercial relation with various states. But it was not till the Revolution of 1848 that Friedrich Wilhelm IV. called together a National Assembly. The Assembly of Frankfurt, the opening of which raised the eager hopes of patriotic Germany, fell into contempt on the refusal by the Prussian king of the imperial title. Bismarck, the able minister of Friedrich Wilhelm Ludwig I., openly declared that a great German parliament could only be founded by 'blood and iron.' The antagonism between P. and Austria, brought to war heat in the

dispute over Schleswig-Holstein (1864), was finally and rapidly settled by Von Moltke at Sadowa in 1866. The chief authority in the Fatherland, for centuries in the hands of Austria, passed now to her rival, with the territory of Hannover, Hessen-Kassel, Nassau, and Frankfurt. Under the presidency of P. was formed the North German Confederation (q. v.), the constitution of which satisfied all but the 'National Liberal' party, whose leading aim was to bring in South Germany. The chief opponents of this party were the Democrats and Ultramontanes. Suddenly the Franco-Prussian War (see GERMANY) swept aside all political faction, and welded together North and South in one common Fatherland, over which, with loud acclaim, King Wilhelm was placed as Emperor. From the brilliant victories of France, Bismarck was called immediately to defend the united Empire against Social Democrats and Ultramontanes. Meantime the party of scholarly Roman Catholics, who, rejecting the dogma of Infallibility, were excommunicated in 1871, had formed the sect of Old Catholics (q. v.), who in 1877 had 21,797 Prussian adherents. The first great event in the conflict of Church and State was the passing of a bill (November 1871) making it penal to preach 'political sermons,' and this was followed in 1872 by the expulsion of the Jesuits. The Ecclesiastical Laws (1873), identified with the name of Dr. Falk, struck at every claim made by the Romish Church in its dealings with the state. They regulated the education of priests, their appointments, and their behaviour to other priests and laymen, while controlling the discipline of the Church, and enforcing by the penalty of heavy fines the filling up of vacant incumbencies. Within two years there were imprisoned five bishops and 1400 priests, while about 100 were driven out of the country, and fines imposed on great numbers. The Falk laws not only meet the temporary emergency of disaffection caused by the abolition of the Temporal Power, but assert the principle that priests must submit themselves to the influence of a lay German training. Later Acts have abolished convents, rendered civil marriages obligatory, and withdrawn state grants from recalcitrant Catholic bishops (1875). The Press Law of 1876 was mainly aimed at Socialism, which has developed so rapidly of late years. In 1877 there assembled at Gotha eighty-eight Socialist delegates, representing 171 local societies, numbering 30,335 members, and in the same year they registered 497,000 votes and returned twelve members to the legislature. The attempts of Hödel (May 1878) and Nobiling (June 1878) to assassinate the Emperor have been taken advantage of to bring forward a measure for the suppression of all Socialist journals, pamphlets, and meetings, by summary process, and while the parliamentary elections are pending (July 1878) Socialists are being prosecuted by hundreds. A correspondence which passed between Pope Leo XIII. and the Crown Prince (June 1878) only demonstrated the hopelessness of any attempt at reconciliation between the Vatican and the Empire. P. preserved strict neutrality during the recent Russo-Turkish war, but the final settlement of the Eastern Question was effected at Berlin by the Congress which was presided over by Prince Bismarck, and which concluded its labours 13th July 1878.

Prussia (Gr. *Preussen*), the largest and most north-easterly province in the kingdom of P., bounded N. by the Baltic, E. by Russia, S. by Russian Poland and Posen, and W. by Pommern and Brandenburg. Area, 24,880 sq. miles; pop. (1875) 3,199,171. It consists of the two former provinces (now administrative districts) of *Ost- und West-preussen*, and is mainly level land, interspersed with tracts of sandy heath and bleak morass. The coast-line is indented by the Gulf of Danzig, the Frische Haff and Kurische Haff, and the chief rivers are the Niemen, Pregel, and Vistula. Of the whole area the percentage of arable land is 48, of

forest 19, and of meadow and pasture 20. The principal crops are wheat, rye, barley, and flax. While cattle and sheep are bred extensively, special attention is devoted to the rearing of horses, of which the province possessed 541,510 in 1873. The industries, which are considerable, include brandy distilling, beer brewing, the spinning and weaving of linen, corn and oil-seed milling, iron smelting, engineering, &c. In 1874 there entered the ports 7237 trading vessels of 1,305,084 tons, and cleared 7144 of 1,288,935 tons. The largest towns are Königsberg, Danzig, Elbing, Tilsit, Memel, Thorn, Insterburg, Graudenz, and Braunsberg. The people, of whom two-thirds are German, comprise 2,202,913 Lutherans, 874,579 Roman Catholics, 41,057 Jews, 11,683 Mennonites, and 4682 Baptists.

Prussian Blue is a deep blue precipitate obtained by adding to prussic or hydrocyanic acid a slight excess of potash, then a mixture of ferrous and ferric sulphate, and finally treating the mixed precipitate of ferric and ferrous oxides, which results with hydrochloric acid. Its formula is Fe_4FeCy_6 . It also results from the action of the ferrocyanide of potassium upon ferric chloride, and forms, therefore, a useful analytical test for ferric salts.

Prussic Acid is the popular name of hydrocyanic acid. Its formula is HCN ; but in discussing the cyanogen compounds, of which this is the type, the radical CN is written ordinarily Cy . The acid is intensely poisonous, and is very volatile, boiling at $26^\circ.5\text{ C}$. It cannot be formed by direct union of its elements, but is usually obtained diluted by the action of sulphuric acid upon the cyanide of potassium. See CYANOGEN.

Pruth, a tributary of the Danube, rises near Mount Rusky, in the Carpathian mountains, in Austrian Galicia, and flows S. and S.E. in a narrow valley through the Bukowina, almost parallel with the Sereth, joining the Danube at Reni, 12 miles below Galatz. It forms the boundary between Moldavia and Russia from Bojana for about 130 miles, and receives on the right the Czeremosz. Near its influx into the Danube it forms the Bratysch Lake. The P. becomes navigable at Jassy, and has a total length of 390 miles.

Prynne, William, the Puritan confessor, was born at Swainswick, Somersetshire, in 1600, and in 1616 proceeded from Bath Grammar-school to Oriel College, Oxford. After taking his B.A. (1620), he entered Lincoln's Inn, where he formed a close friendship with the schismatical Dr. Preston, and wrote his *Perpetuities of a Regenerate Man's Estate* (1627), *Violence of Love Lockes* (1628), *Heathens Sickness, or a Compendious and Briefe Discourse proving the drinking and pledging of Healties to be sinfull and utterly unlawfull unto Christians* (1628), and other anti-Arminian treatises. The first of these Laud contented himself 'with burning in private, without any sentence passed against it;' but at length the four words, 'Women actors notorious harlots,' occurring on p. 1104 of the *Histrionic-Matrix, the Player's Scurge, or Actor's Tragædie* (1633), were construed, with an odd compliment to the queen, into a necessary reflection on her virtue. For this libel and other railings against stage-plays, huntings, 'devil's Christmas,' bonfires, Maypoles, 'cringing and ducking to altars,' and church music, which P. described as 'a bleating of brute beasts, where choristers bellow the tenor as it were oxen, bark a counterpoint as a kennel of dogs, roar out a treble like a set of bulls, grunt out a bass as it were a number of hogs,' he stood arraigned in the Star Chamber, February 7, 1633, and was sentenced to have his book burnt by the common hangman, to stand twice in the pillory and lose both his ears, to be put from the bar and degraded in the university, to pay £5000, and to suffer perpetual imprisonment. Four years after the infliction of this punishment, P. was again brought up with two others, Burton and Bastwick, to answer for fresh libels, when, to a repetition of his former sentence ('involving,' says Kennet, 'a cropping of the very remainder of ears'), was added the clause 'that he be stigmatised on the cheeks with two letters, S. and L., for Seditious Libeller,' but which P. interpreted as *stigmata Laudis*—the stamps of Laud. The account in Howell of how he, Burton, and Bastwick were, on June 30, 1637, pilloried and curtalsed like curs, is as pitiful as anything contained in Foxe or Challoner. From the castle of Mont-Ogueil, in Jersey, whither he had been shifted from Caernarvon, P. in 1641 addressed a petition to the House of Commons, which resulted in the reversal of both sentences and in his triumphal return to London, in time 'to strike proud Canterbury to the heart.' Of the £4000 voted him as compen-

sation, he never received a farthing, but he was returned by Newport to the Long Parliament, and created Recorder of Bath (1647). He got on, however, no better with the new than the old regime, and, 'rankled with a contrary heat,' was again imprisoned in 1650 and 1652, in the latter year being also deprived of his recordership. After the Restoration, which he had zealously promoted in the Convention Parliament, Charles II. proposed 'to keep busy Mr. P. quiet by letting him write against the Catholics, and pore over the records in the Tower,' with whose keepership he was accordingly intrusted. In July 1661 he for the last time incurred the censure of the House for a seditious libel, being *Sundry Reasons against the Corporations Bill*, and, having no longer stomach for the fight, thenceforth employed himself 'in clearing the Augean stable of our national antiquities' down to his death at Lincoln's Inn, October 24, 1669. 'Voluminous P.,' as Wood happily styles him, well earned the epithet by some 200 treatises, bristling with squadrons of authorities. A little over-parted in the great drama of his times, he played with wearisome painstaking and stubborn boldness, and the single light feature in his character is an occasional touch of cunning. See vol. iii. of Howell's *State Trials*, and *Documents relating to William P., with a Biographical Fragment by the late John Bruce* (edited by S. R. Gardiner for the Camden Society, 1877).

Przemysl, one of the oldest towns of Galicia, kingdom of Austria, on the San, an affluent of the Vistula, 55 miles W. of Lemberg by rail. It has several fine Gothic churches, and a ruined castle of the princes of P., who ruled a great Russian principality of that name. There are linen and leather industries. Pop. (1870) 15,185.

Przibram, a town of Austria, in Bohemia, on the Litawka, an affluent of the Moldau, 35 miles S.S.W. of Prague. It is the seat of a mining school, and in the vicinity are silver mines, the yield of which amounts to from £2000 to £2500 yearly. Pop. (1870) 9825.

Psalmana'zar, George, the name assumed by a notorious impostor, supposed to have been born in the South of France in 1679. After receiving a good education from the Jesuits, and holding a tutorship at Avignon, he commenced a vagabond life, now as an Irish pilgrim, now as a native of Formosa. In the latter character he met at Sluys one Innes, a knavish army chaplain, who, hoping thereby to advance his own preferment, baptized the soi-disant heathen, and brought him to London. Here P. found a patron in Bishop Compton, for whom he wrote a *History and Description of Formosa off the Coast of China* (1704), with maps of the island and copious specimens of the Formosan language, and by whom he was sent to Oxford to complete his studies. Detection or repentance led him in his thirty-second year to abandon the cheat, and he turned hack-writer, leading thenceforward a sober, studious life, which earned him Johnson's praises as a modest, pious, and amiable man. He died in London, May 3, 1763, leaving behind him an *Essay on Miracles by a Layman* (1793), and *Memoir of —, commonly known as George P., a reputed Native of Formosa* (1764).

Psalmody is the act or the art of singing religious songs in the worship of the Deity, coeval with society itself. Prizes were given at the Pythian Games in Greece to those who sang the best hymns to the gods. Julian the Apostate said the best hymns to the gods were composed by the gods themselves, or by men inspired by a divine spirit. And among the ancient Egyptians a chief part of their worship consisted of singing hymns to the gods. The name of P. is derived from the Psalms or sacred songs of the Hebrews, who are supposed to have derived their music from Chaldea. The Book of Psalms (q. v.) was the hymn-book of the second temple.

In the Christian Church, singing formed a part of divine service from the very first. The Psalms were sung (1) sometimes by one person alone; (2) sometimes by the whole congregation, led by a precentor; (3) sometimes alternately, by the congregation divided into choirs; (4) sometimes by one person singing one part of the verse and the rest joining in the close of it. As to the mode of singing, it was of two kinds: plain song, something like intoning, and a more artificial mode, with a variety of notes. The first to place P. on a popular footing was St. Ambrose (340-397), who partially introduced the Greek musical

system into the Church. But Pope Gregory the Great (540-604) is regarded as the actual composer and organiser of modern P., as well as the author of a regular system of music.

P. was a universal characteristic of the Reformation. Indeed the Lollards (q. v.), precursors of the Reformation in the 14th c., seem to have received their name from their constant practice of praising God with psalms or hymns. A great impetus was given to P. when the Psalms were rendered into verse, which was first done in the 16th c. by Marot (q. v.), the court-poet of France, who thereby unintentionally helped forward the Reformation. Sternhold published a metrical version of fifty-one psalms in 1549, and the remainder were translated by Hopkins, Whittinghame, &c. This version was supplanted in England about the beginning of the 18th c. by one made by Tate and Brady, and in Scotland about the middle of the 17th c. by one made by Rous. Among the Presbyterians of Scotland no hymns, chanting of the prose psalms, or anything but the metrical psalms, was permitted in P. till very recently.

Psalms, Book of, in the Hebrew canon is a collection of 150 songs of a religious character. The Greek *Psalmos* (a lyric poem) corresponds to the Hebrew title *mizmôr*, which occurs in the superscription of a number. In that of others the name is *shîr* (song), and the title of the book is *Tehillim* (songs of praise). The whole collection is divided, perhaps in imitation of the five-fold division of the Pentateuch, into five books, ending with (1) xli., (2) lxxii., (3) lxxxix., (4) cvi., and (5) cl. The first four are closed with a doxology—'Blessed be the Lord,' &c. (cf. xli. 13). The traditional view regarding the authorship of the P. is that they were all written by David, but the superscriptions of a number of them name other persons as their authors. Some critics, indeed, hold that no reliance is to be placed on the superscriptions as a clue to the authorship, since they are not authentic. Taking the superscriptions, however, for what they are worth, one psalm is ascribed to Moses, seventy-three to David, two to Solomon, twelve to Asaph (called a seer or prophet, 2 Chron. xxix. 30), eleven to the sons of Korah (a family of servants of the Temple, 1 Chron. ix. 19), one (lxxxviii.) to Heman the Ezrahite, a son of Korah (1 Chron. vi. 33), to whom it is also ascribed, one to Ethan the Ezrahite (1 KINGS iv. 31), and forty-nine are anonymous. The collection bears every appearance of having been formed gradually. By the best authorities it is thought that the first two books (i.-lxxii.) were compiled before the Captivity, and that the whole was completed by Nehemiah. Taken as a whole, these P. are the most wonderful expression of religious emotion that literature can show. There is not a height of rapture nor a depth of agony which they do not reach. The variety and richness of their sentiment, including every phase of hope, joy, fear, grief, faith, reverence, and gratitude that can move the human heart in its relations to God, make them, next to the words of our Lord himself, the most precious heritage of the Christian Church; nor is it conceivable that a day will ever come when they will cease to be a light to the feet and a lamp to the path, or will fail to pour balm into wounded hearts, give rest to weary souls, and inspire with heavenly faith those that are walking through the valley of the shadow of death. See Bleek's *Einführung in d. A. T.* (Eng. trans. 1869). The best commentaries are, in Latin, Calvin's (Gen. 1578); in English, Horne's (Oxf. 1771), Peirce's (Lond. 1860); in German, Hitzig's (Heidel. 1836; new ed. 1865), De Wette's (Heidel. 1836; new ed. 1856), Ewald's (Gött. new ed. 1866), Olshausen's (Leips. 1853), Hupfeld's (Gotha, 1855), Delitzsch's (Erl. new ed. 1867; Eng. trans. Edinb. 1873).

Psammetichus (hieroglyphic *Psmtck*), King of Egypt from 671 to 617 B.C., was the founder of the Saitic dynasty (the twenty-sixth of Manetho). On his father Necho being put to death by Sabacon, the Ethiopian usurper, P. fled to Syria, where he remained till restored by the inhabitants of the Saitic district. Here he reigned as one of the *Dodecarchy*, or federation of twelve kings, who after Setho's death ruled Egypt in common, until, according to Diodorus, P. having acquired vast wealth by trade with the Phœnicians and Greeks, was enabled to raise a large force of Arabian, Carian, and Ionian mercenaries, and with them totally defeat all his rivals at Momemphis (about 652). Hence he assigned to the Greek soldiers a settlement below Bubastis, making a number of Egyptian children live with them, who thus learned Greek, and from whom sprang the class of interpreters. To the Greeks, too, he gave the

place of honour on the right wing, as in his Syrian expedition. Indignant at this, 240,000 of the Egyptian soldiers left Egypt, and founded in Ethiopia the kingdom of the Automoli (deserters). P., after a siege of twenty-nine years, took Azotus from the Syrians, and by large presents averted a Syrian invasion (626 B.C.). He first gave free access into Egypt to foreign traders and emigrants, e.g., the Jews (Isa. xix. 18, Jer. xlv. 1), encouraging especially the Greeks, by opening to them the west branch of the Nile, and forming an alliance with Athens. P. courted the priesthood, building many sacred edifices—e.g., the propylæa of the temple of Vulcan, and the aula and portico before the temple of Apis at Memphis. Sculpture, too, was revived, and learning, especially the study of languages, was vigorously promoted, and a new style of handwriting, the demotic, was introduced.

Psitta'cidæ. See PARROT.

Pskov, or **Pleskov**, a government of European Russia, surrounded by the governments of St. Petersburg, Novgorod, Tver, Smolensk, Vitebsk, and Livonia. Area, 17,069 sq. miles; pop. (1870) 717,186 (10,000 Esthonians). P. is an undulating plain, watered by the Velikaia and Lovat, the surface being generally flat and sandy, with here and there hills and swamps. The climate is temperate. About one-third of P. is forest, and one-half is under cultivation, the chief product being flax.—P., the chief town, on the Velikaia, 178 miles S.S.W. of St. Petersburg by rail, is well built, with broad streets and strong walls. The finest buildings are the Kremlin, the Cathedral, the Government Buildings, and the Priests' College. P. is the seat of a Greek archbishop, and has forty-two churches and four monasteries. Russia leather, linens, and sailcloth are manufactured, and there is a large trade with Narva and St. Petersburg. At the close of the Middle Ages P. was connected with the Hansa, and had a pop. of 60,000. From 1509 it has belonged to the Russian Empire. Pop. (1870) 18,331.

Psoralea is a large genus of shrubby or herbaceous *Leguminosæ* of somewhat variable habit. They have pinnate or tripartite leaves; blue, white, or purple flowers in spikes or racemes, and one-seeded pods. *P. esculenta* of N. America possesses tuberous farinaceous roots, which are much used by the Indians for food, and bear the name of 'prairie turnips.' In Chili the foliage of *P. glandulosa* is infused as a medicinal tea, and the root employed as an emetic, &c. Seeds of the E. Indian *P. corylifolia* are rubefacient, and are specific for leucoderma; the pods yield an oil. P. is predominant in America and Cape of Good Hope. Its name, from Gr. *psoraleos*, 'scurvy,' has reference to a sort of glandular coating of many of the species.

Psoriasis (Gr. *psora*, 'a cutaneous eruption'), is a common chronic skin eruption, characterised by thickened patches of skin varying in size, covered by silvery scales, and with a red base. In the ordinary non-syphilitic P. the patches are situated chiefly on the outer sides of the limbs, the elbows, and the knees. There are several forms of P., as *P. guttata*, in which the patches are very small, as if they had been dropped or dredged on the skin. When the patches assume a circular shape it is termed *P. diffusa*, and when peculiarly obstinate *P. inveterata*. The causes of P. are very obscure, and although non-contagious, it is often hereditary. It is common to both sexes, all ages, and every condition of life, although it is more frequent in middle and advanced life than in childhood. The treatment consists in the administration of saline purgatives, a vegetable and milk diet, and abstinence from all stimulants; a warm bath should be taken daily. In the syphilitic variety, mercury in some form is necessary, and when the eruption is secondary, a rapid cure may be effected by fumigation. In non-syphilitic cases the best remedy is arsenic, which should be given till the physiological effects appear; or arsenic may be given in combination with mercury, as in Donovan's solution. Tar capsules have also been given with advantage. Tar in some form is the best local application, as the *unguentum pictæ*, or the Barbadoes tar. Sulphur and vapour baths are also often useful.

Psyche, in Homer means the departed spirit or ghost—the immortal part of man; from the time of Herodotus it is used to denote the soul in man, but the idea is first personified in Appuleius (q. v.). He tells us that a certain king had three

daughters, of whom P., the youngest, was very beautiful. To her were dedicated some of the altars of Venus, and this so excited the wrath of the goddess that she commanded Cupid to inspire her with love for a monster. But Cupid, becoming himself enamoured of her, bore her to a secret spot, where he visited her every night. Being told by her sisters that in the darkness she was nightly embracing some loathsome creature, P. at one of Cupid's visits lighted a lamp and beheld his beauty. A drop of hot oil from the lamp fell on Cupid's shoulder, and he fled with reproaches. P. then tried to destroy herself, and at last Venus entranced her with a sleep brought from Hades. Thus she slumbered until Cupid returned and touched her with the point of an arrow. Venus was reconciled, and Jove united the lovely pair.

Psychology is the science of mind based upon the facts of consciousness. The name first appeared in modern philosophy in the work of Goclenius entitled *Psychologia* (Marb. 1594). P. has been divided into empirical P. and rational P. The former has to do with the phenomena of consciousness; the latter with the nature of the soul. P. is in the present day mainly studied through physiology, the correlation of mind and brain chiefly engaging attention. See MIND, PERCEPTION, &c.

Ptarmigan (*Lagopus vulgaris*), a species of *Rasorial* birds belonging to the family *Tetraonidae*. The genus *Lagopus* also

Ptarmigan.

includes the Red Grouse (*L. Scoticus*), and is distinguished by having the legs and tarsi fully feathered. The P. is the smallest of British grouse. It occurs also in N. Europe, and is notable for the remarkable change in colour which its plumage undergoes in winter. In the latter season it is nearly all white; in summer its plumage becomes mottled with grey and black, so as to produce a colour which perfectly hides the bird from view, harmonising exactly with the tints of the stones and ground where it lives. The adult P. attains a length of 15 or 16 inches.

Pterichthys (Gr. 'winged fish'), a well-known genus of fossil Ganoid fishes belonging to the Old Red Sandstone series, and confined to Devonian rocks. They were first discovered by Hugh Miller, after whom the most familiar species (*P. Mulleri*) is named. Other species are *P. cornutus*, *P. latus*, &c. The P. presents a highly typical arrangement of the ganoid covering. The head and front part of the body were covered with great bony plates, whilst a back-plate and breast-plate also formed a buckler-like shield. These ganoid plates were firmly united by sutures. The tail was also covered with ganoid scales of smaller size. A dorsal fin of small size was developed, and the tail-fin, as in all ganoids, was *heterocercal* or unequally lobed. The ventral fins were small, but the pectorals were large, and have given origin to the name 'P.' They consisted of a strong jointed process, covered with small scales, and according to Owen they must have been used in enabling the P. to shuffle along the sandy bottom or sea-beach left dry by the receding tide. The teeth were small.

Pterocles. See GANGA.

Pterodactyl (Gr. 'wing-finger'), a genus of extinct *Reptilia*, forming the type of the order *Pterosauria*, and named from the extreme length of the outermost of the fingers, which formed a support for a *Patagium* (q. v.), or *wing-membrane*. This patagium consisted (like that of the bats) of an expansion of the skin of the body, and stretched from the finger along the sides of the body to the hind limbs, and between the hind limbs and tail. The P. was enabled by this membrane to support itself in the air, and to fly as perfectly as the existent bat. No living reptiles have a true power of flight. The little *Draco volans*, or flying dragon of the E. Archipelago, has a parachute-like expansion of the skin in the front region of its body, supported on several of the anterior ribs; but this membrane does not invest the reptile with powers

of flight, and merely serves to support it in its flying leaps from tree to tree. The P. remains occur in Mesozoic rocks, and are found from the Lower Lias to the Middle Cretaceous rocks inclusive. The lithographic slates (or Oolite) of Solenhofen in Bavaria contain P. remains in great abundance. Most P. are of small size, but some specimens must have measured over 20 feet in expanse of wing. *P. crassirostris*, *P. longirostris*, *P. medius*, &c., are familiar species. No outer skeleton of scales existed in these animals. Their jaws were long, and were provided with teeth. The bones were pneumatic or contained air, and the breast-bone bore a medium ridge keel to which the great pectoral or wing-muscles were attached. The coracoid bones of the shoulder were of large size, and the collar-bones were undeveloped.

Pteromys. See FLYING SQUIRREL.

Pteropoda (Gr. 'wing-footed'), a small class of *Mollusca*, closely allied to the *Gasteropoda* (q. v.). They are represented by certain small organisms of oceanic habits found chiefly in the Arctic Seas. They are popularly known as 'sea-butterflies,' and appear to approach the surface of the ocean chiefly at night. The genera *Clio* ('Whales' food'), *Hyalaea*, and *Cleodora*, include the best-known genus of this group. The shell when present is a delicate vitreous body of conical shape. The gills may be imperfectly developed. Their characteristic name is derived from the possession of two wing-like appendages or *epipodia*, borne on the sides of the neck, and by the movements by which they swim through the sea. They occur in such numbers in the Arctic Seas that they appear to form the chief food of the Greenland whale, which draws them in shoals into its mouth, where they are retained by the *baleen* or whalebone plates. In their development they pass through stages identical with the early stages of *Gasteropod* development. The adult *Pteropod* is, in fact, an immature *Gasteropod*.

Pteropus. See KALONG BAT.

Pterosauria (Gr. 'winged lizard'), an order of extinct reptiles represented by the *Pterodactyl* (q. v.), &c., and which possessed powers of flight. Their fossil remains are limited to Mesozoic rocks. The chief genera besides the *Pterodactyl* are *Ramphorhynchus*, which had no teeth in the front of either jaw, and *Dimorphodon*, which had large well-developed front teeth. The tail in the latter genus was probably abortive; that of *Ramphorhynchus* was long and slender.

Pterygotus (Gr. 'wing-shaped'), a well-known fossil genus of *Crustaceans* belonging to the order *Eurypterida*. *P. anglicus* attained a length of 6 feet. Its remains occur in rocks ranging from the Upper Silurian to the Upper Devonian. The front part of the body was covered by a carapace; two large compound eyes, and small single eyes were developed, and five pairs of legs were present. Thirteen segments succeeded the head, and the *telson* or tail-segment was frequently spinous. These extinct *Crustaceans* appear to be related to the living *Limuli* or King Crabs.

Ptolemaic System is the system of astronomy which was generally accepted by astronomers after the time of Ptolemy (q. v.). How much of the system is really Ptolemy's it is hard to say; but to him we owe its explanation, and probably much of its development and elaboration. The earth was supposed fixed in the centre of a huge sphere, the *primum mobile*, which carried the heavenly bodies along with it in its daily revolution. The annual motion of the sun and the monthly motion of the moon were accounted for by supposing these luminaries to travel in eccentric circles round the earth. The necessity for this was previously pointed out by Hipparchus. To explain the planetary motions, other complexities had to be introduced. Each planet was supposed to move uniformly in a circle (*epicycle*) round a point, which itself moved uniformly in an eccentric circle round the earth. Every planet required its own peculiar epicycle, and as observational astronomy advanced, new modifications and contrivances had to be introduced. The system, though cumbersome compared to the Newtonian system, is not to be regarded merely as a vain attempt to reduce all motion to uniform circular motion—the *perfect* motion of the ancients. It was an ingenious method for forecasting the positions of the planets. It was sufficiently accurate for the times, and abounded in beautiful geometrical applications. Even Copernicus had to introduce epicycles

into his system, when it became evident that assumed circular motion gave results not even approximately true. The Copernican system as first promulgated was hardly a logical refutation of the P. S.; an acute partisan of the latter could easily have held his own against a supporter of the former. The discoveries of Galileo, however, were irresistible to the candid mind, and the labours of Kepler and Newton secured the doom of the doctrine of the fixed central earth.

Ptolemaïs. See **ACRE**.

Ptol'emy I. (*Ptolemaïos*), surnamed **Soter** ('the Saviour'), born 367 B.C., was the son of Arsinoë, mistress of Philip of Macedon. He was the reputed son of Lagus, a man of humble rank, although Philip was probably his father. He became a great favourite at court, and a confidant of Alexander; but for encouraging the prince to seek in marriage the daughter of Pixodarus, King of Caria, Philip sent him into exile. Recalled by Alexander in 336, he followed that monarch through all his campaigns. At the death of Alexander, when his generals divided the empire among themselves, P. became governor of Egypt, and put to death Cleomenes, the former satrap. He had now to make sure his ground against Perdicas, an old colleague. A war broke out in 321, and Perdicas was slain. Marrying Eurydice, daughter of the regent Antipater, P. next seized Phœnicia and Cœle-Syria, and took possession of Jerusalem on a Sabbath. In subsequent struggles with Antigonus, the most powerful of Alexander's generals, he lost Phœnicia in 311, and Cyprus in the memorable sea-fight near Salamis in 306. Antigonus proclaimed himself king, and P. followed his example. For enabling Rhodes to withstand the attack of Demetrius, son of Antigonus, the Rhodians bestowed on P. the title of Saviour. On the death of Antigonus in 301, the struggle for mastery ceased. Syria, Palestine, and Cyprus fell under Egyptian sway, and the rest of P.'s reign was peaceful. He governed in a liberal spirit, restored to the Egyptians the rights of their castes and priesthoods, and fixed his capital at Memphis. He laid the foundation of Egypt's prosperity, and made Alexandria the first commercial city in the world. He likewise encouraged letters, and in his palace could have been found the great Euclid, Stilpo the Megarean, Theodorus the Cyrenian, Diodorus Cronus, Philetas the poet, and Zenodotus the grammarian. He corresponded with Menander, and Antiphrilus and Apelles painted for him. In 285 he announced that he had ceased to reign, and that his throne passed to his youngest son. The young king was hailed with enthusiasm, his elder brothers appearing at the coronation. The father died in 283.—**Ptolemy II.**, surnamed **Philadelphus**, the youngest son of the preceding and Berenice, was born in the island of Cos, 309 B.C. He had been educated with care, and developed his father's enlightened policy. But in order to secure his throne he put two of his brothers to death, an act which, some suppose, gained him the derisive name of Philadelphus. Others say that the title arose from his great affection for his sister Arsinoë, whom he married, after repudiating his first wife. He cleared Egypt of robbers, established traffic with tribes in Ethiopia, opened Southern Africa to Alexandrian merchants, constructed ports, and dug canals. He built and furnished magnificent museums, and gathered all the literary treasures procurable into the great Alexandrian Library, of which Zenodotus and the poet Callimachus were the first librarians. His court was the rendezvous of all men of talent. According to an ancient though long-discredited belief, the Septuagint (q. v.) or Greek version of the Hebrew Scriptures was drawn up at his command for the sake of the Alexandrian Jews. He built the celebrated lighthouse on the island of Pharos, and removed the ashes of Alexander to a magnificent mausoleum. He maintained a standing army of 200,000 foot soldiers and 40,000 cavalry, and a fleet of 15,000 vessels. He died 247, leaving colonies in various parts of his dominions, which comprised Cœle-Syria, Palestine, Cyprus, Lycia, Caria, the Cyclades, portions of Ethiopia, Arabia, and Syria.—**P. III.**, surnamed **Euergetes** ('benefactor'), eldest son of the preceding, came to the throne in 247 B.C. To avenge the murder of his sister Berenice, wife of Antiochus III., King of Syria, he marched to Antioch, ravaged Syria, and conquered Babylonia and Mesopotamia. He returned with immense booty, and restored to the Egyptians the idols Cambyses had carried off. By this act he earned the title of Benefactor. Polybius says he died a natural death in 222, but Justin says that he was

poisoned by his son and successor.—**P. IV.**, son of the preceding, was born 242 B.C. He was surnamed **Philopator** ('lover of his father'), some say derisively, on account of his parricide, but this can hardly be, as he adopted the name on his medals. He commenced to reign in 222, putting to death his mother Berenice, his brother Magas, and his uncle Lysimachus. His minister Sosibius instigated him to these and many other crimes, and, enfeebling his master by all sorts of debauchery, obtained all but the name of king. Roused by the success of Antiochus the Great, who threatened an invasion of Egypt, P. sent an army and a fleet against the Syrians in 218. These were defeated; but in the following year he commanded in person, and completely routed Antiochus at Raphia. Returning by way of Jerusalem, and being refused admittance into the sanctuary, he conceived a deadly hatred of the Jews, depriving those in Alexandria of all their privileges, and even persecuting them. Relapsing into a vicious life, he left the power in the hands of Sosibius and Agathocles, brother of his mistress. These men governed so badly that the Egyptians revolted. During this reign Egypt greatly deteriorated, and it was a day of joy when the king died, in 205.—**P. V.**, surnamed **Epiphanes** ('illustrious'), born about 210 B.C., was placed on the throne at the age of five. During his minority the power fell into the hands, first of Agathocles, and next of Sosibius, son of Sosibius mentioned above, and finally of Tlepolemos, a brave soldier but a poor statesman. Philip, King of Macedon, and Antiochus III., King of Syria, took advantage of P.'s youth to regain their conquered possessions. Philip reclaimed the Cyclades and the maritime towns of Thrace, while Antiochus obtained Cœle-Syria. At the intervention of the Romans a treaty was formed by which P. was to marry Cleopatra, daughter of Antiochus, and recover the Syrian provinces (199). Aristomenes became Egyptian prime minister, and the king was invested with full power (196). The coronation, which took place at Anactaria, gave rise to the inscription on the celebrated stone of Rosetta, the key to all hieroglyphs. For some time his reign was singularly peaceful, but, disregarding the wise counsels of Aristomenes, whom he caused to be put to death, he fell into habits of debauchery, and was poisoned in his thirtieth year.—**P. VI.**, surnamed **Philometor** ('lover of his mother'), eldest son of the preceding, ascended the throne in 181 B.C. He was then a minor, and his mother Cleopatra governed Egypt. After her death the power passed into the hands of two incapable ministers, Euxenus and Lenæus, who rashly engaged in a war with the King of Syria. The King of Syria defeated the Egyptians, and gained possession of P., upon which his younger brother was appointed at Alexandria to succeed him. But the King of Syria allowed Philometor to reign at Memphis, leaving the brother, Euergetes, at Alexandria. Euergetes at length drove Philometor from Memphis, and caused him to appeal to the Romans. At Rome he was received with honours, and an embassy which returned with him arranged that he should govern in Egypt, while Euergetes obtained Cyrene. Euergetes soon laid hold upon Cyprus also, and in this attempt the Romans to a small extent assisted him. He was taken prisoner at Lapethus, but liberated on condition that he contented himself with Cyrene. Then P. turned his arms against Demetrius Soter, King of Syria, in favour of the pretensions of Alexander Balas. He succeeded in placing this man on the throne, and gave him his daughter Cleopatra in marriage. Alexander was so little grateful as to connive at an attempted assassination of his father-in-law, and P. dragged him from the throne, took back his daughter, and made the son of Demetrius King of Syria. Alexander again struggled for the throne. In a battle between Alexander's forces and the Egyptians, P. fell from his horse and sustained such injuries that he died (146). It is said of this king that his humanity was great, and that he never put an Alexandrian to death for any offence.—**P. VII.**, surnamed **Euergetes II.**, or **Physcon** ('pot-bellied'), brother of the preceding, was raised to the throne in 146 B.C. He married his sister Cleopatra, widow of Philometor. His reign was one of cruelty and bloodshed. His conduct towards the Alexandrians was so bad that large numbers of them emigrated, and certain quarters of the town had to be peopled with foreigners. The incests and cruelties of the king were so outrageous that he was driven to Cyprus by his exasperated subjects, and only returned on suzerainty in 127. He died ten years after his restoration. His single virtue was a

love of letters, and he left a set of Commentaries (*Hypomnemata*) which is lost to us. There were as many as thirteen of the P. dynasty.

Ptolemy, properly **Clau'dius Ptolemæ'us**, the mathematician, astronomer, and geographer, lived at Alexandria, Egypt, during the early part of the 1st c. of the Christian era. We know him only through his writings, the importance of which in the history of science cannot be over-estimated. In how far his works are original or simply collections of what had been made out before his time, it is impossible to say. He himself expressly states that he largely availed himself of the work of his predecessors, especially of Hipparchus. Indeed it is from his *Almagest* that we gain most of our knowledge regarding the discoveries of Hipparchus. This work contains all that was then known of astronomy. The theory which it advocates is noticed under **PTOLEMAIC SYSTEM**. The great discoveries of Hipparchus (q. v.) are supplemented by the discovery of the evection of the moon, the disentanglement of which from the other lunar inequalities is the greatest triumph of ancient astronomy. The discovery was made by P. from the recorded observations of Hipparchus. There is little doubt that P., though a splendid mathematician, was a bad observer; but it is to his credit that he was the first, after a lapse of more than 200 years, who could appreciate the labours of Hipparchus. The 7th and 8th books of the *Almagest* are the most interesting to the modern astronomer, giving the longitudes and latitudes of 1022 stars. His great geographical work—*Geographike Hyphegesis*—was the standard treatise on the subject till the maritime discoveries of the 15th c. disclosed its deficiencies. He gives an estimation of the size of the earth, introduces an improved method of projecting a hemisphere upon a plane surface, and fixes all his places by latitude and longitude. There are other works ascribed to him bearing upon astrological subjects and upon the phenomena of the fixed stars; but his fame lives in his valuable treatises on astronomy and geography. He is the one authority among the ancients upon these subjects. The best edition of the *Almagest* is by Halma (Par. 1813–20). The catalogue of stars was published separately by Francis Baily in the *Memoirs of the Royal Astronomical Society* (1843). The best editions of the Geography are the *editio princeps* of the Greek text by Erasmus (1533), the Elzevir edition (1619), and the Latin versions of 1482 and 1490.

Pto'sis (Gr. 'a falling') signifies a drooping or falling of the upper eyelid, which may be the result of injury or of paralysis of the levator-palpebræ muscle. When P. is caused by paralysis it may be cured by treatment of the nervous affection on which the paralysis depends; but when this fails a surgical operation may be required to reopen the eye, and restore its power of vision.

Ptychodus, a fossil genus of *Elasmobranchiate* fishes allied to the Port Jackson Shark (*Cestracion Philippi*). Its remains occur in the Cretaceous rocks alone. The teeth were quadrate in shape, and had their summits thrown into folds or ridges of transverse shape.

Publica'ni (Lat. *publicum*, 'all that belong to the state'), were the farmers of the revenue of the Roman state, which never collected its own taxes, but sold them by auction through the censors. A company (*socii, societas, corpus*) of wealthy Roman citizens, never freedmen or slaves, bought up for a definite sum one, rarely more, of the provincial taxes, such as tolls, tithes, harbour dues, scriptura or rent of the state pastures, duties for the use of mines and salt works, &c., giving security for payment, and then collected the taxes for their own benefit. The usual lease was for five years (*lustrum*); from the time of Constantine only three. The responsible person in each company who contracted with the state was called *maniceps*, the chief agent at Rome, annually elected, *magister*, and his representative in the provinces, *sub magistro* (of Luke xix. 2). The underlings, often freedmen and slaves, who collected the taxes, behaved usually with shocking fraud and rapacity. Such were the 'publicans' of the New Testament. As early as the Second Punic War, after the battle of Cannæ, we read of the P. accompanying the state with loans; about fifty years later the companies included almost none but Equites (q. v.), who had almost all the public revenue in their hands, served as a public bank, and were justly regarded as the very foundation of the state.

Public Bur'dens, a term of Scotch law denoting the taxes and assessments upon land. They fall on the landlord, when there is no stipulation to the contrary, except the schoolmaster's salary, which is equally divided between landlord and tenant.

Public Health Act (38 and 39 Vict. c. 55). This important Act, which became law on the 11th of August 1875, repeals and embodies the Public Health Acts, the Local Government Act, the Nuisance Removal Acts, the Sanitary Acts, the Sewage Utilisation Acts, and Diseases' Prevention Act, either entirely or partially, as detailed in the first and second parts of the fifth schedule of the Act. It does not extend to Scotland or Ireland, nor to the metropolis, except where expressly stated. It contains 343 sections, and is divided into eleven parts as follows:—I. *Preliminary*, is almost entirely composed of definitions and titles. II. *Authorities for Execution of the Act*, provides for the division of the whole of England into rural and urban sanitary districts, describes the authorities, and defines their powers. III. *Sewerage and Drainage*, provides authorities with the necessary powers for constructing sewers and dealing with sewage, and confers on local authorities powers to enforce drainage where necessary. It enacts penalties for building houses without necessary accommodation; provides for the scavenging and cleansing of streets, the removal of filth, and the purification of houses. It provides for the supply, storing, and protection of water; regulates lodging-houses; defines nuisances; forbids the establishment of unhealthy trades in urban districts; the traffic in unhealthy or unsound meat; and contains provisions as to the prevention of infectious and epidemic diseases, and the establishment of hospitals and mortuaries. IV. *Local Government Provisions*, relates entirely to urban districts, and regulates matters concerning highways, streets, buildings, markets, public pleasure-grounds, and police. V. *General Provisions*, deals with contracts, the purchase of lands, byelaws, conduct of business, and the appointment and duties of the officers of local authorities. VI. *Rating and Borrowing Powers*, defines and makes provisions for meeting the expenses by rates; gives power to borrow for certain sanitary purposes, and provides for the audit of accounts. VII. *Legal Proceedings*, details the legal procedure for the prosecution of offences, the recovery of penalties, and lays down the manner in which notices are to be served. VIII. *Alteration of Areas and Union of Districts*, gives power to the Local Government Board regarding such matters for sewerage and general purposes, and for the purpose of appointing medical officers of health. It provides also for the constitution, expenses, &c., of port sanitary authorities. IX. *Local Government Board*, relates to the powers, orders, and proceedings of the Local Government Board. X. *Miscellaneous and Temporary Provisions*, concerns entry on lands, penalties for obstructing the execution of the Act, and compensation in certain cases; the clerk and treasurer of certain authorities, special district rates, main sewerage and district sewerage boards, &c. XI. *Saving Clauses and Repeal of Acts*, contains various saving clauses, and is followed by the schedules.

The Public Health (Scotland) Act became law on 15th August 1867. It contains 122 clauses, and is divided into eight parts. *Part I., Local Authority and Board of Supervision*, defines the constitution and powers of these bodies. II. *Removal of Nuisances*, gives power of entry to local authority or their officers, and details proceedings by local authority where nuisances are ascertained to exist. It also deals with the sale of unwholesome meat, the purity of water supply, and offensive trades. III. *Prevention and Mitigation of Diseases under Order in Council*, confers powers upon the board to carry out orders of the Privy Council, to appoint medical officers of health, to provide for the interment of the dead, for house to house visitation, and for all that may appear advisable for preventing or mitigating epidemic, endemic, or contagious diseases. IV. *General Prevention and Mitigation of Disease*, relates to the providing of hospitals, means of disinfection, the removal of patients to public hospitals, regulations as to lodging-houses and under-ground dwellings, penalties on persons suffering from contagious diseases exposing themselves, infected houses and clothing, and provision as to ships within the jurisdiction of the local authority. V. *Regulation of Common Lodging-Houses*, confers powers on the local authorities to make rules and regulations. VI. *Sewers, Drains, and Water Supply*, provides for the purchase, construction, and cleansing of sewers, and the utilising of sewage; the formation

of drainage districts, the trapping of sewers and the drainage of houses; the supply of water for burghs; special water-supply districts; the purchase of lands, &c. VII. *Assessments*,—provides for special drainage and burgh assessments. VIII. *Enforcement of and Procedure under this Act*,—states conditions under which a local authority may be proceeded against in the event of neglect of its duty. The P. H. (Scotland) A. has, in many respects, been a great boon to Scotland in the way of sanitary improvement; but its chief defect consists in its permissive nature. The only amendments to the Act of 1867 have been two short Acts giving an increased power of assessment with regard to water supply, and extended provisions with regard to sanitary loans. See *Spens' Sanitary System of Scotland* (1876).

Public-Houses, Law Regarding. See BEER ACTS; HOTELS; INNKEEPER LICENSING ACTS, &c.; and for Scotch Law, FORBES MACKENZIE ACT.

Public Schools, The, of England, may be defined as schools held under a trust for the advantage of the public. They vary, however, considerably in their character, two, Eton and Winchester, being collegiate foundations, with a provost, a warden, and fellows; others charges upon cathedral chapters, e.g., Westminster and Canterbury; others entrusted to the care of municipal companies or civic corporations, as St. Paul's, Merchant Taylors, and Ipswich; others, especially those of recent origin, proprietary institutions, like Marlborough and Cheltenham. Several are grammar-schools, founded in the 16th c. for the yeomanry of the surrounding district; and of these Harrow from its position, and Rugby from its wealth, have risen to be among the greatest schools in England. In some education is free, or offered at a reduced rate to a limited or privileged number of scholars, e.g., at Eton or Dulwich; in others, as Birmingham and Manchester, it is free to all alike. The education furnished by these schools is everywhere much the same, classics forming the general basis of instruction, but mathematics, modern languages, and natural science gaining increased importance with every year. That university distinctions are not necessarily dependent on wealthy endowments, is shown by the fact, recorded in the Commissioners' Report, that Westminster in ten years produced but 2 first-class men and 1 wrangler, whilst Shrewsbury furnished 14 first-class men and 7 wranglers in the same period—a fact which becomes intelligible when we consider that some of our ablest scholars have held the head-masterships of smaller schools, Valpy of Norwich, Donaldson of Bury, and Kennedy of Shrewsbury. The real great distinction amongst these schools is wealth, the annual cost of sending a boy to Eton being often brought up by personal expenses (school subscriptions, pocket-money, &c.) to considerably over £200. In the following list, which is for the spring of 1878, such personal expenses are not taken into account, and it should be mentioned that at most schools an entrance fee is demanded of from two to ten guineas.

Bedford Grammar School, founded in 1552, endowed by Sir William Harpur in 1566, and recently reconstituted, has 1 exhibition of £70 and 1 of £60, each tenable for 4 years at a university or other place of continued education. Terms for boarders, from £72 to £75; for day-boys, from £9 to £12. Masters, 16; boys, 274.

Brighton Proprietary College, established in 1847, has 8 Council Scholarships open to boys at the school and tenable for 1 year, viz., 1 of £20, 1 of £15, and 3 of £10 for boys under 15; and 1 of £25, 1 of £20, and 1 of £10 for boys over 15. There are also 3 Soames Scholarships of £50, and 3 Council Scholarships of £30, tenable for 3 years at either Oxford or Cambridge, and 1 Wakeford Attree Scholarship of £60, tenable for 2 years at Cambridge alone. Terms for boarders, from £72 to £75; for day-boys, from £8, 10s. to £11, 10s.; sons of clergymen at reduced rates. Masters, 14; boys, 200.

Charterhouse (q. v.), removed under the Public Schools Act of 1868 to Godalming in Surrey, 4 miles S.S.W. of Guildford by rail, possesses 30 junior scholarships of £65, open for competition to boys between 12 and 14 not at the school, and tenable up to 16; 10 junior exhibitions of £20; and 30 senior scholarships of £85 for boys between 14 and 16, tenable up to the time of leaving. There are also 5 exhibitions of £80, to be held for 4 years at a university or other place of continued education. Terms for boarders, £100 to £110; for day-boys, £30. Masters, 31; boys, 500 (the full number).

Cheltenham Proprietary College, established in 1848, has annual elections to 12 scholarships, viz., 6 of £40 for 3 years, and 2 of £20 for 2 years, open to boys under 13 at the school; with 2 of £40, and 2 of £20 for 3 years, open to boys under 16. There are also the Dobson Scholarship of £60, tenable for 1 year after leaving school, and the Wyllie Scholarship of £50, tenable for 3 years at Trinity College, Oxford. Terms for boarders, from £68, 10s. to £88, 12s.; for day-boys, from £17, 10s. to £21, 10s. Masters, 42; boys, 647.

Christ's Hospital (q. v.), has on an average 6 university scholarships annually, of £90 for 4 years. Masters, in London, 29; at Hertford, 8. Boys, in London, 682; at Hertford, 372.

City of London School, established by the corporation of London in 1834, is one of the wealthiest institutions in the kingdom, possessing 19 scholarships and exhibitions tenable at the school, and ranging from £20 to £25, with free education; besides 25 of from £22 to £60, tenable at a university or other place of continued education. Terms for day-boys, who alone fall within the school system, £10, 10s. Masters, 27; boys, 671.

Clifton Proprietary College, established in 1867, has 9 scholarships varying from £25 to £50, viz., 2 entrance scholarships for boys of 12, 2 scholarships for boys under 15 and 2 for boys under 16, 2 Guthrie Scholarships for boys under 17, and the Cay Mathematical Scholarship. Terms for boarders, from £98 to £86; for day-boys, £25. Masters, 42; boys, 604.

Dulwich College has 35 scholarships of £20 for boys between 12 and 14, of which 3 are tenable for 3 years, the rest during continuance at school; and 8 exhibitions of £50, tenable at an English university, or by 'a student of some learned or scientific profession or of the fine arts.' Terms for boarders from £68 to £81; for day-boys from £15 to £18, or if sons of residents in St. Giles, Camberwell, St. Luke, Finsbury, St. Saviour, Southwark, and St. Bodolph, Bishopsgate, from £12 to £15. Masters, 32; boys, 560. See DULWICH.

Eton College (q. v.) has 70 foundation scholarships, open for competition to boys between 12 and 15, and tenable up to 19. There are also the Newcastle Scholarship, of £50 for 3 years at Oxford or Cambridge; 2 Chamberlayne Exhibitions of £50 for 4 years; 3 Reynold's Exhibitions of £48 for 4 years at Exeter College, Oxford; 2 postmasterships of Merton College, Oxford, tenable for 4 years, &c. Terms for Oppidans, £150; for Collegers, free. Masters, 50; boys, 938.

Haileybury College, near Hertford, established in 1864, has 2 scholarships of £30 and 1 of £20, open to all boys between 12 and 14, whether at the school or not; 2 classical exhibitions of £50 for 4 years at Oxford or Cambridge; and 1 mathematical of £50 for 4 years at any place where mathematics form the staple of instruction. Terms for boarders, there being no day-boys, from £74 to £110, or 10 guineas less for sons of clergymen. Masters, 21; boys, 360.

Harrow (q. v.) has about 6 entrance scholarships yearly of from £30 to £60, open to boys under 14; and there are also 1 Gregory Scholarship of £100 for 4 years, 1 Spencer of £30 for 3 years, and 1 Botfield of £60 for 3 years, all tenable at either Oxford or Cambridge, besides 2 Sayer Scholarships of £52, 10s. for 4 years at Caius College, Cambridge; 2 Baring of £100 for 5 years at Hertford College, Oxford; 2 Neeld of £30 for 3 years at Oxford, and 1 Leaf at £70 for 3 years. Terms—for boarders, from £98 to £178, 10s.; for day-boys, £28, 10s., or with private tuition, £43, 10s. Masters, 32; boys, 512.

King Edward's School, Birmingham, founded in 1552, gives free education to boys above 8 whose fathers are inhabitants of Birmingham, Handsworth, Aston, Harborne, Edgbaston, or King's Norton, and has 10 Founder's Exhibitions of £30 for 4 years at Oxford or Cambridge, 3 Milward Scholarships of £50 for 4 years, 1 Leach Mathematical Scholarship (interest of £500 stock), and 1 James Exhibition of £30. Masters, 26; boys, 573.

King's College School, London, established in 1830, has 1 Forest Classical and Divinity Scholarship of £30 for 3 years, 1 mathematical of £30 for 3 years, and 1 Inglis for English literature of £20 for 1 year, besides 16 choral exhibitions, whose holders pay only half fees. There are no scholarships tenable after leaving school. Terms for boarders, from £88 to £94; for day-boys, who form the bulk of the school, from £24 to £30. Masters, 37; boys, 580.

Manchester Free Grammar School, founded in 1515 by Hugh Oldham, Bishop of Exeter, has 2 Shakespeare Scholarships of £20 for 2 years and 2 of £14 for 1 year, 20 Langworthy Scholarships

of £20 for 1 year, and 2 Walker Scholarships of £20 for 1 year. There are also 2 yearly scholarships of from £50 to £60 for 5 years at Brasenose College, Oxford; 5 exhibitions of £50 for 3 years at St. John's College, Cambridge; 1 Rickards Scholarship of £50 for 3 years at either university; 6 Brackenbury Scholarships of £45 for 3 years at Oxford; 2 exhibitions of £50 for 4 years at Wadham College, Oxford; and 3 exhibitions of £17 for 3 years at Owens College, Manchester. The education of the scholars, who are all day-boys, is free. Masters, 30; boys, 850.

Marlborough College has 15 yearly Foundation Scholarships of £30 for sons of clergymen between 10 and 15, whether members of the school or not, 2 Senior Scholarships of £50 for boys under 15, 1 Ireland Scholarship of £15 for sons of clergymen under 15, and 1 House Scholarship of £80 for boys under 14, all tenable during continuance at the school; besides 6 Junior Scholarships of £30 for 2 years, 2 Authors' Mathematical Scholarships of £15 for 1 year, and 2 Modern School Scholarships of £20 for 1 year. There are also 10 exhibitions of from £22, 10s. to £50 for 3 years at either Oxford or Cambridge. Terms,—for boarders, £85; for day-boys, £26. Masters, 34; boys, 565. See MARLBOROUGH.

Merchant Taylors' School, founded in 1561, has 6 Junior Scholarships of £15 for 2 years open to boys under 14, and 4 Senior Scholarships for boys under 16 of £30 during continuance at school. There are also 21 scholarships at St. John's College, Oxford, tenable for 7 years. Terms for day-boys, who alone are recognised by the school system, from £12, 12s. to £15, 15s. Masters, 21; boys, 500.

Repton Grammar School, 6½ miles S.S.W. of Derby, founded by Sir John Porte in 1556, has 1 yearly scholarship of £40 for 4 years, open to boys between 13 and 15, and 1 yearly exhibition of £50 for boys leaving the school. Terms for boarders—there being no day-boys—£87, 10s. Masters, 18; boys, 250.

Rossall School, near Fleetwood, Lancashire, founded in 1844, has 8 or 10 Entrance Scholarships annually, of from £10 to £40, 2 or 3 of them being Senior Scholarships (for boys under 15), tenable for 3 years, and the remainder Junior Scholarships (for boys under 14) tenable for 2 years. There are also 3 exhibitions of £50, and 3 of £30, for 3 years at Oxford or Cambridge. Terms for boarders—there being no day-boys—from £63 to £73, 10s., or 10 guineas less for sons of clergymen. Masters, 19; boys, 266.

Rugby (q. v.), besides its foundation benefits, has 9 public scholarships open to boys under 15, viz., 2 classical of £80, 2 of £50, and 1 of £20; 1 mathematical of £50 and 1 of £20; 1 French and 1 natural science, each of £20. There are also 3 Major Exhibitions of £60 and 3 Minor Exhibitions of £30, tenable for four years at any university in the United Kingdom or some other place of continued education. Terms,—for boarders, £120; for day-boys, £40. Masters, 27; boys, 460.

Sherborne Grammar School, founded in 1550, has 16 Foundation Scholarships of £22, 10s. (the fee for tuition), and one yearly exhibition of £40 for 4 years at either university. It is essentially a boarding-school, the terms being £78, 15s. Masters, 20; boys, 265. See SHERBORNE.

Shrewsbury Grammar School, founded in 1551, whilst possessing no scholarships tenable at the school, has 13 open to boys who are leaving it; viz., 4 Millington Exhibitions of £63 and 1 of £60, 2 Smyth's Exhibitions of £36, 1 Matthews' Exhibition of £40, 1 Taylor Exhibition of £23, and 2 others of £35, all tenable at either University; besides 1 exhibition of £10 tenable at Oxford alone, and 1 of £17, 10s. at St. John's College, Cambridge. Terms,—for boarders, £84; for day-boys, £21. Masters, 9; boys, 164.

St. Paul's School, founded in 1512 by John Colet (q. v.), has 77 Foundation Scholarships in the Classical and 76 in the Modern School, which confer on their holders exemption from all tuition fees, and 51 of which are awarded after competitive examination to boys between 12 and 14. Terms, for day-boys, of whom the school consists, £20. Masters, 9; boys, 180. Under a scheme approved by the Queen in Council, March 24, 1876, St. Paul's is hereafter to comprise a Classical School for 500 boys (a site for which, near the Addison Road Station, was purchased for £32,000 in June 1878), a Modern School for the same number, and a High School for 400 girls.

Tunbridge Grammar School, founded in 1552 by Sir Andrew Judd, according to a new scheme, is to have certain Judd Scholarships granting exemption from tuition fees for 2 years, and 4 Boarding Scholarships, open to boys under 14, of £50 for 4 years; besides

4 yearly exhibitions of from £50 to £100 for 4 years at any university or other place of higher education. Terms,—for boarders, £85; for day-boys, £21. Masters, 20; boys, 229.

University College School, London, established in 1832, has 1 Case Exhibition of £20, 1 Trevelyan-Goodall Art Scholarship of £20, and the Holloway Exhibitions, endowed from a bequest of £2000. There are no scholarships tenable after leaving the school, which is a day one. Terms, £25, 4s. Masters, 43; boys, 635.

Uppingham School, founded in 1584, has, besides its foundation benefits, 2 public scholarships of £50 and 2 of £30 for 3 years open to boys under 14, besides 2 scholarships of £50 for 2 years open to boys under 17. There are also 3 exhibitions of £60, £50, and £40 respectively, tenable for 3 or 3½ years at a university or other place of continued education, and a Mathematical Prize of £30. Terms,—for boarders, £110; for day-boys, £30. Masters, 24; boys, 300. See UPPINGHAM.

Wellington College, near Wokingham, Berkshire, founded as a memorial to the Duke of Wellington, gives free education to a certain number of orphan sons of commissioned officers in Her Majesty's army, or the army of the late East India Company. It further offers to boys between 12 and 14, whether members of the school or not, 2 scholarships of £50, 2 of £40, and 2 of £30, all tenable for 2 years; and to members of the school under 16, 2 of £50 and 1 of £40 for 3 years. There is another scholarship of £50 for 3 years, tenable at the school or at the universities, and 1 of £30 for 2 years, also tenable there, at Woolwich, or the universities. Terms for non-foundations, who, like the foundationers, are all boarders, from £80 to £135. Masters, 24; boys, 375.

Westminster School, founded by Queen Elizabeth in 1560, has 40 Queen's Scholarships, entitling their holders to free tuition, and open to all members of the school under 15; 2 exhibitions of £30 and 2 of £20 (or £50 and £30 in the case of boarders), tenable for 2 years, and open to boys between 12 and 14 whether members of the school or not; and 1 Mure Exhibition of £40 for boys between 15 and 17. There are also 3 junior studentships at Christ Church, Oxford, of £100 for 7 years; 3 exhibitions at Trinity College, Cambridge, of £40 for 3 years; and 2 exhibitions at either university of £50 for 3 years. Terms, for boarders, £100; for day-boys, £31, 10s. Masters, 21; boys, 196.

Winchester College (q. v.) has 70 foundation scholarships of £50, tenable up to 18, and open to all boys between 12 and 14, whether members of the school or not; besides 8 exhibitions of £50, and others of £21, for boys between 15 and 16, all tenable during good behaviour. There are 6 New College Scholarships, 1 Goddard Scholarship, and 1 Bedminster Exhibition. Terms for commoners, £107. Masters, 24; boys, 385.

To these may be added *Boteler Grammar School* (1526), with 6 masters and 100 boys; *King Edward's School* (1553), Broms-grove, Worcestershire, with 6 masters and 75 boys; *Durham Grammar School* (1541), with 11 masters and 140 boys; *King Edward VI's School* (1542), Great Beilhamsted, with 11 masters and 144 boys; *King's School*, Canterbury, with 10 masters and 125 boys; *Leamington Proprietary College*, with 9 masters and 126 boys; *King Edward VI's School* (1547), Norwich, with 13 masters and 121 boys; *Queen Elizabeth's School*, Ipswich, with 9 masters and 85 boys; *Radley College*, near Abingdon, with 12 masters and 133 boys; *Richmond School* (1567), Yorkshire, with 9 masters and 86 boys; the *Royal Naval School* (1833), at New Cross, Kent, with 12 masters and 161 boys; *St. Andrew's College* (1853), at Bradfield, near Reading, with 12 masters and 126 boys; and the *Stationers' School* (1838), with 12 masters and 190 boys. See *Report of Commissioners on Certain Colleges and Schools* (4 vols. 1864); *The Public Schools Calendar* (Lond. 1866); T. Markby, *Public Schools*, in the *Contemporary* for 1867; K. Staunton, *The Great Schools of England* (new ed. Lond. 1875); and C. E. Pascoe, *Handbook to the Principal Schools of England* (new ed. Lond. 1878).

Public School System of the United Kingdom. In England the education of the common people originated in a religious and philanthropic movement. Robert Raikes of Gloucester (1735–1811) founded the Sunday-school system, in which at first secular as well as religious instruction was given. In 1808 the British and Foreign School Society, and in 1811 the National Society for Promoting the Education of the Poor in the Principles of the Church of England, were established (see JOSEPH LANCASTER and ANDREW BELL). Popular edu-

cation was maintained by the unaided efforts of these agencies till 1833, when for the first time state aid was given to education in England, in the form of a grant of £20,000, to be divided equally between the two great societies, and to be devoted to the building of schools. Meanwhile, numerous and vigorous efforts to induce Parliament to adopt a national system all signally failed. Mr. Whitehead in 1807, Lord Brougham in 1816, 1820, and again in 1835, and Mr. Wyse in 1835 and 1837, were compelled to succumb to clerical and obscurantist opposition. At length, in 1839, action was taken, but only on a denominational basis, and in a supplementary form. The government of Lord John Russell prevailed on Parliament to appoint a Committee of the Privy Council specially to administer a public education grant. In the first year, the applications for aid amounted to £48,590, made in behalf of 58,302 children, and the sum voted by Parliament amounted to £30,000. The Committee did much to stimulate local effort in the establishment and maintenance of schools by offering a capitation-grant of ten shillings for every child to be accommodated; and great improvement was effected in the quality of education by the appointment of inspectors, and by the foundation of normal schools, or training colleges. In 1846 the Committee of Council took another and most important step. With the view of inducing a higher class of men to become teachers, annual augmentation grants and pensions were promised to all that obtained by examination certificates of merit, and whose schools were from year to year reported as efficient; and the local authorities were required to pay to the teacher double the amount of the public grant. With the view of maintaining a supply of well-trained teachers, the system of paid pupil-teachers was commenced, and pupil-teachers were induced at the close of their apprenticeship to enter the training colleges by the offer of Queen's Scholarships. Under the minutes of 1846, an immense impetus was undoubtedly given to education; but a strong feeling of dissatisfaction gradually arose in the country from the rapid strides of the expenditure, the huge multiplicity of agencies, and the growing deficiency of results. Notwithstanding the special grants to poor rural schools, begun in 1853, and in 1856 extended to poor town schools, many districts, and these of course the most necessitous, were still without schools; while the grant that in 1839 had amounted to £30,000, and in 1849 to £125,000, had in 1859 increased to £770,000. Complaints, too, were heard, that as the grants were earned by general efficiency, clever children received special attention, and those less intelligent were comparatively neglected. In 1860 appeared the Revised Code of Regulations, the work of Mr. Robert Lowe, the then vice-president of the Committee of Council, by which grants were offered on the average attendance and the individual examination of the scholars, and were to be paid to the managers, not to the teachers of the schools. The introduction of this Code gave a serious shock to the education of the country. Difficulty was experienced in recruiting the ranks of teachers, and the tone of good schools was lowered by cram taking the place of education, and by the consequent neglect of the higher subjects of instruction. Nor was the scheme justified by its economical success; for though the grants fell to £693,078 in 1865, they had risen in 1870 to £914,721. The deficiency of proper school accommodation, moreover, was still so great, that upwards of a million of children were unprovided for. To supply this want, Mr. Forster's Act (1870) was passed, which established as near an approach to a national system as the ecclesiastical condition of the country permitted. Where school districts voluntarily supply the requisite accommodation, the schools remain under private management, and obtain the Parliamentary grant, provided that intellectual and religious education are separated, and that no scholar is compelled to receive religious instruction. Where districts neglect to supply the requisite accommodation, or where direct application is made for the purpose, by order of the Education Department, school boards are elected to do the work, and are empowered to use the local rates. Board schools are placed under the management of the boards, with the restriction that no distinctive religious catechism or formula shall be taught; and boards are authorised to make bye-laws enforcing the attendance of children from five to thirteen years of age. This Act was supplemented in points of detail by the Elementary Education Act (1873), and by the Elementary Education (Orders) Act (1874). School boards have been formed in London, in 123 out of 223 boroughs, and in 1667 out of 2346 parishes, and

have under their jurisdiction 12,829,381 of the population. There are 1604 board schools, with accommodation for 556,539 children, and with an average attendance of 333,234. The Loan Commissioners have paid to school boards for works of a permanent character £5,152,274, and the amount of school rate for 1876 was £868,318. Bye-laws enforcing school attendance have been sanctioned for London, for 109 municipal boroughs, and for 612 civil parishes, comprising 11,221,563 of the population. Accommodation having been thus fully supplied, it became necessary to create extended compulsory powers with the view of filling the schools. This was done by Lord Sandon's Act (1876), by which school-attendance committees were to be formed by Town Councils in boroughs, and by Boards of Guardians in parishes which have no school board. These committees are armed with threefold compulsory powers, partly direct, partly indirect. It is illegal to employ any child under ten years of age, and to employ a child between ten and fourteen, who does not possess a certificate of proficiency, or of previous school attendance. A parent who habitually neglects his child may be fined, and a child habitually consorting with vagabonds or criminals may be sent to a day industrial school. Attendance committees have the same power as school boards to frame compulsory bye-laws; but, at the date of the last report, out of 106 borough and 412 rural committees only 27 had communicated with the Department on the subject. Special reference must be made to the work of the school boards of London and Birmingham. The Metropolitan Board has under its control 242 schools, with 163,008 places, and a staff of 1816 adult teachers, and 1959 pupil-teachers; while it has received from the Loan Commissioners for building purposes £2,080,480. —Under the New Code now in operation, grants are made in aid of elementary schools and of training colleges. (See TRAINING COLLEGES). Elementary schools may earn grants of various sums on the average attendance of the scholars, the number of infants present on the day of examination, the number of passes obtained by individual examination, and the results of the class examinations. The subjects of individual examination are reading, writing, and arithmetic; and of class examination, grammar, history, elementary geography, and plain needlework. Special grants are made for passes in the following higher subjects:—English literature, mathematics, Latin, French, German, mechanics, animal physiology, physical geography, botany, and domestic economy. The highest annual grant per scholar obtainable under the Code is 27s. Grants are also made in respect of pupil-teachers. (See PUPIL-TEACHERS.)—Some idea of the recent progress and present state of education in England may be obtained from the following statistics. In 1870, the schools inspected for grants provided for 1,878,584 scholars, or 8·5 per cent. of the population, and in 1877 for 3,653,418 scholars, or 14·88 per cent. From 1871 to the middle of 1877, the population between the ages of three and fifteen increased 414,000, or 6½ per cent.; during the same period additional accommodation was provided in efficient public elementary day-schools for 1,413,639 scholars, an increase of 70 per cent. In 1870 there were on the school registers the names of 1,693,059 children, or 7·66 per cent., and in 1877 the names of 3,154,973 children, or 12·85 per cent. In 1870 there were in average attendance 1,052,389, or 68·06 per cent. of the registered scholars; and in 1877, 2,150,683, or 68·1 per cent. In 1870, the scholars in average attendance who were qualified by attendance to earn grants on individual examination numbered 923,842, or 80·16 per cent.; and in 1877 they numbered 1,436,008, or 66·75 per cent. Of the scholars qualified for individual examination who were actually examined, there were, in 1870, 765,584, or 82·86 per cent.; and in 1877, 1,335,118, or 92·96 per cent. Of those individually examined in 1870, there passed in reading 91·66 per cent.; in writing, 88·93 per cent.; in arithmetic, 78·31 per cent.; the corresponding percentages for 1877 being 85·78, 78·89, and 69·97. In 1877 there were examined in the following specific subjects:—English literature, 44,790; physical geography, 18,936; mathematics, 3806; animal physiology, 13,032; mechanics, 584; Latin, 616; French, 1850; German, 51; botany, 913. The certificated teachers number 25,292, the assistants 5168, and the pupil-teachers 31,780. The total amount of the education grant for England, for 1876-77, was £1,880,640, of which there was paid to Church of England schools £1,019,218; to British, Wesleyan, and other schools, £283,286; to Roman Catholic schools, £94,419; and to board

schools, £316,906. The cost of administration was £163,791, of which £109,832 was paid for inspection. There are 121 inspectors, and 98 inspectors' assistants. The average salary of certificated masters was £115, 7s. 2d., and of mistresses, £68, 16s. 0d.

The famous parish schools of SCOTLAND were founded throughout that country by an Act of the Scottish Parliament in 1696 re-enacting a former statute of 1646. Under this Act the heirs were bound to provide a commodious schoolhouse, and an annual salary not above £11, 2s. 2½d., nor under £5, 11s. 1½d. In 1803, and again in 1861, improved provision was made for the supply of school-buildings, and for the support of the schoolmaster. By the latter Act, the schoolmaster was also released from the obligation to sign the *Confession of Faith*, and certain modifications were made on the *ad vitam aut culpam* tenure under which he held office. In 1839, the Parliamentary grants administered by the Privy Council Committee were made to Scotland, and from 1839 to 1870 amounted to £1,452,538. The action of the Privy Council in England during that period applied also to Scotland, except that payments under the Code of 1860 continued to be made to Scotch schools until 1873. In 1872, Lord Young's Act, the seventh attempt to establish national education in Scotland, became law. It vests the general administration of the system in a Scotch Education Department of the Privy Council. The local management of the schools is entrusted to school boards, established in every parish and burgh, and empowered to raise funds by a local rate. Teachers appointed under the Act hold office during the pleasure of the boards. Religious instruction may be given in the schools under specified regulations, and with the protection of a conscience clause. Every parent is bound under penalty of fine or imprisonment to teach his children between five and thirteen reading, writing, and arithmetic; and if he is too poor to pay fees, his parochial board must do so for him. Certain of the old burgh schools were also included in the Act under the designation of Higher Class P. S., and school boards were enjoined to administer them exclusively with a view to promote the higher education. These schools have no share in the Parliamentary grant, but their buildings are maintained, their examinations conducted, and allowances granted to their teachers on retirement, at the expense of the school fund. They are now 18 in number—Aberdeen, Arbroath, Ayr, Dumfries, Dunfermline, Edinburgh, Elgin, Glasgow, Haddington, Hamilton, Irvine, Leith, Montrose, Paisley, Peebles, Perth, Stirling.—The educational progress of Scotland under the Act of 1872 may be estimated from the following facts. In 1873, the schools inspected for grants provided for 294,072 scholars, or 8½ per cent. of the population; and in 1877, for 535,949 scholars, or 15 per cent. In 1873 there were on the school registers the names of 280,581 children, or 8½ per cent. of the population, and in 1877 the names of 472,668 children, or 13½ per cent. In 1873 there were in average attendance 220,508, or 7½ per cent. of the registered scholars, and in 1877, 360,413, or 76½ per cent. In 1873, of the scholars in average attendance, 134,483, or 60 per cent., were examined by the inspectors; in 1877, 249,661, or 69 per cent. Of those individually examined in 1873, there passed in reading, 97·8 per cent.; in writing, 91·4 per cent.; in arithmetic, 86·2 per cent.; the corresponding percentages for 1877 being 93·15, 88·05, and 80·58. In 1877, there were examined in the following specific subjects:—Mathematics, 1627; English literature, 10,265; Latin, 3958; Greek, 200; French, 1783; German, 78; mechanics, 62; chemistry, 217; animal physiology, 4019; light and heat, 133; magnetism and electricity, 646; physical geography, 9982; botany, 411; domestic economy, 6367. The certificated teachers number 4698, the assistants 289, and the pupil-teachers 4751. The total amount of the education grant for Scotland for 1877 was £482,017, 6s. 6d., of which public schools received £346,680, and denominational schools £106,695. There are 25 inspectors of schools, and 18 inspectors' assistants; and the cost of inspection was £21,691. The average salary of certificated masters was £135, 6s. 3d., and of mistresses, £71, 8s. 7d. In 1877 there were in all 2425 public schools, *i.e.*, schools under school boards. Since the Act came into operation, 858 new public schools have been built, and 500 old school buildings have been enlarged, the new accommodation thus provided being for 214,800 pupils. In addition, the Board of Education has, up till June 1878, sanctioned the erection of 243 new schools and 63 enlargements, providing together for 40,873 pupils.

The Board has sanctioned the application of 705 boards for leave to borrow, in all, the sum of £2,195,210, 9s. 9d., for the purpose of providing or enlarging schools.

After the conquest of IRELAND by the English, various statutes were passed to provide education for the Irish people, chiefly, however, with the view of proselytising them to the Protestant faith. In 1831, a united national and non-sectarian system of education for the lower classes was founded by Government. Its declared object was to afford a combined literary and a separate religious instruction to children of all religious persuasions; and its administration was vested in a Board of Commissioners, who now number twenty. The schools to which aid is granted are: (1) Vested schools, which are vested in the commissioners or in trustees for the purposes of the national system, and to the building, repair, and furnishing of which the Board has contributed; (2) Non-vested schools, the property of private individuals, to which the Board contributes aid only in the form of salaries, books, and requisites; and (3) Model schools which belong wholly to the Board. Concessions have repeatedly been made to the demands of denominationalists, and at the present time the fundamental principle of the system is carried out in its integrity in the model schools alone. The local government of the schools is entrusted to patrons or managers, subject to the approval of the Board. Teachers are arranged in three classes, the salaries ranging, for males, from £58 to £32 per annum; and for females, from £48 to £32. The wretched condition of Irish teachers recently engaged the attention of Parliament, and the National School Teachers Act (1875) was passed with a view of obtaining increased local contributions in response to special State grants, but all efforts to render the Act effective have failed. On the 31st of December, 1876, there were 7334 national schools in operation, of which 2127 were vested, and 5207 non-vested. The number of registered scholars in *bona fide* attendance was 596,427, and the average daily attendance 416,586. The number of registered scholars which made at least one attendance was 1,032,215, of whom 79·4 per cent. were Roman Catholics, 9 per cent. Episcopalians, and 10·8 per cent. Presbyterians. The model schools numbered 29, with a gross attendance of 16,029, of whom 4599 were Roman Catholics, 5449 Episcopalians, and 4755 Presbyterians. The workhouse schools were 158 in number, with 12,790 registered scholars. The number of teachers under the Board was—principals, 7072 (males, 4411, females, 2661); assistants, 3205 (males, 742, females, 2463); junior assistants, 127; work-mistresses, 327. There were also 4280 paid monitors. The total income of the teaching staff was £638,508, 16s. 8d., of which 27·6 per cent. was locally provided, and 72·4 per cent. paid by the State. The amount of the Parliamentary grant was £645,949.

Scotland.—*Reports of Committee of Council on Education, 1840-73*; *Reports of the Scotch Education Department, 1875-77*; *Reports of Board of Education for Scotland, 1873-77*; *Reports of Royal Commissioners, 1864-68*, nine volumes. Ireland.—*Reports of the Commissioners of National Education, 1833-77*; *Report of the Royal Commission, 1870*, six volumes.

Pub'na (*Pubná*), the chief town of the district of the same name, Bengal, British India, on the right bank of the Ichamutti, a channel which joins the Ganges and the Brahmaputra, 130 miles N.E. of Calcutta. Pop. (1872) 15,730. It conducts a considerable trade in jute and rice.—The district of P., which lies at the angle formed by the junction of the two great rivers above mentioned, has an area of 1966 sq. miles. Pop. (1872) 1,211,504, of whom 70 per cent. are Mohammedans. The staple crops are rice and jute. Besides the two great bordering rivers, the whole country is intersected with navigable watercourses. In 1876-77 the total exports were valued at £2,205,000, including jute £863,000, rice £142,000, oil-seeds £276,000; the imports were valued at £2,324,000, including piece-goods £421,000, salt £360,000, sugar £126,000. The trade is conducted both by country boats and by steamers. The manufactures are gunny, indigo, and paper. P. has for the last few years been the scene of a combination among the cultivators to resist enhancement of rent.

Puck's (*pakha*), a word in universal use in Anglo-Indian phraseology, signifying complete, substantial, perfect of its kind, the contrast in every sense of *kutcha*. A P. appointment

is one that is confirmed; P. news is authentic; a P. house is built of brick or stone. The word is derived from a Sanskrit root, signifying 'ripe, mature, cooked'; cf. Gr. *pepō*, 'I cook.'

Pückler-Muskau, Hermann Ludwig Heinrich, Fürst von, was born of an ancient family at Muskau in Lausitz, October 30, 1785. After studying law at Leipsic (1800-1803), he entered the body-guard at Dresden, and subsequently travelled in Austria, France, and Italy, returning to Muskau to succeed his father in 1811. Here he lived in retirement until the war of 1813, when he entered the Russian service as major. He became adjutant to the Duke of Weimar, and a lieutenant-colonel. In 1815 he returned to private life, and soon after visited England, where he remained more than a year. After returning to Muskau he began to form his extensive and celebrated park-gardens, which he has himself described in his *Andeutungen über Landschaftsgärtnerei* (Stuttg. 1834). In 1817 he married the Countess of Pappenheim, but was separated from her in 1826. In 1822 he was elevated to princely rank by the king of Prussia, and in 1828 he again visited England, remaining there and in France for a year. Afterwards he travelled through Algeria and the N. of Africa, Greece, Egypt, and part of Asia. On his return he lived at Muskau, until he sold that property in 1845. He died at Branitz, February 4, 1871, without issue. As a writer, P. was first known by his *Briefe eines Verstorbenen* (4 vols. Mun. 1830, and Stuttg. 1831). This is a diary of travel in England, Wales, Ireland, France, Germany, and Holland, and contains vigorous painting of manners and customs. His other works are *Tutti frutti*; *aus den Papieren des Verstorbenen* (5 vols. Stuttg. 1834); *Jugendwanderungen* (Stuttg. 1835); *Semilasso's vorletzter Weggang*; *Traum und Wachen*; *aus den Papieren des Verstorbenen* (3 vols. Stuttg. 1835); *Semilasso in Africa* (5 vols. Stuttg. 1836); *Der Vorläufer* (Stuttg. 1838); *Südöstlicher Bildersaal* (3 vols. Stuttg. 1840); *Aus Mehemed-Ali's Reich* (3 vols. Stuttg. 1844); *Die Rückkehr* (3 vols. Berl. 1846-48). P.'s literary remains (letters and diaries) have been edited by Ludmilla Ausung-Grimelli (8 vols. Berl. 1874, *et seq.*), who has also written a biography of P. (Hamb. and Berl. 1872-74). See also Petzoldt's *Fürst H. von P.-M. in seinem Wirken in Muskau und Branitz, sowie in seiner Bedeutung für die bildende Gartenkunst Deutschlands* (Leips. 1874).

Pudd'ing, under this term is embraced an endless variety of food preparations which occupy an important though subsidiary place on the dinner-table. It is possible to classify the varieties of P. under three heads, meat P., fruit P., and sweet P., but all manners of combinations are made according to the skill and daring of the cook. Sweet P. embraces the leading kinds commonly eaten, and the monarch of all is the plum P., which is known and appreciated in every place where the English language is spoken. Plum P. within itself embraces the leading ingredients which go to the composition of all puddings—currants, raisins, suet, almonds, flour, bread, milk, spices, sugar, eggs, wine, and brandy. Rice, sago, tapioca, arrowroot, and similar starches are much employed as the bases of P. which are simply made with addition of milk, eggs, and flavouring essence, and baked in a P. dish.

Pudd'ing-Stone. See CONGLOMERATE.

Pudd'ling. See IRON.

Puebla, or La Puebla de Los Angeles, a city of Mexico, capital of a state of the same name, stands on a tableland 7137 feet above the sea-level, 76 miles S.E. of the city of Mexico. It was founded by the Spaniards in 1531, and its fine Doric cathedral, noted for the splendour of its interior, was commenced in 1552. The city, which stands at the foot of Mount Popocatepetl, and not far from the river Tlascala, is regularly built and well paved. The houses are flat-roofed, and many are three stories high, and profusely ornamented. There are 69 churches, 3 hospitals, 15 elementary schools, 20 religious houses, a theatre, a public library, and a museum. P. is one of the most important commercial towns of the Confederation, is connected by rail with Jalapa, Mexico, and Vera Cruz, and has large cotton and woollen manufactures. The Mexicans under Ortega were here besieged by the French under Forey and Bazaine from the 18th March to the 14th May 1863. Pop. 67,571.

Puerperal Fever is a disease belonging to the so-called zymotic class, the proximate cause of which is some peculiar

poison to which lying-in women are liable by contagion, or which is, under certain circumstances, developed in the puerperal state. The type and the symptoms of P. F. may vary, but the poison is an essential factor in its causation. In some instances peritonitis is the leading symptom; in others, metritis; in others, phlebitis; and, in the most fatal cases of all, sudden collapse from the intensity of the poison, without any local lesions being discoverable after death. P. F. is due to a peculiar poison of the nature of which we are ignorant; but the mortality from this cause has of late years been greatly reduced, chiefly as the result of the more advanced knowledge which modern hygiene has developed in regard to the laws relating to the spread of zymotic diseases generally. The aggregation of patients in lying-in hospitals of defective construction is a cause of greatly increased maternal mortality; and should the poison of P. F. once become developed, decimation of parturient women has not unfrequently been the result. There is some reason for supposing that the puerperal poison may be developed from other poisons of a similar kind, and that the cause is less specific in its nature than a septic influence operating upon the peculiar conditions of the puerperal state. The great danger which a woman incurs who, during the puerperal period, is exposed to contagious diseases, such as typhus and scarlet fever, is clearly recognised in the etiology of the disease. Smallpox contracted under similar circumstances is almost invariably fatal. P. F. is an eminently contagious disease.

Treatment.—The nature of the treatment to be adopted, in cases of P. F., must depend upon the type of the disorder, and also upon the stage at which the case is seen. Indiscriminate blood-letting is to be deprecated, but depletion is applicable when the earliest symptoms indicate acute inflammation of the peritoneum, of the uterus, or of both; but if the patient has passed the acute stage, bleeding is most injurious, and more especially in asthenic cases. When the bowels do not respond to an ordinary dose of medicine, it should be supplemented by an enema. Ipecacuanha has been recommended by some and calomel by others, but the latter is more efficacious when combined with opium. Blisters to the abdomen have been tried, but without any very satisfactory results. The external application of warm poultices or turpentine fomentations will be much more beneficial. When the type of the disease is asthenic, stimulant and tonic regimen should be prescribed from the first. Quinine, in doses of from 15 to 30 grains in the day, has been found beneficial.

Puerperal Ma'nia may be developed during pregnancy, after parturition, or during nursing; but the disease is invariably one of exhaustion, debility, and prostration. The symptoms of P. M. do not differ materially from those which are exhibited by patients who are subjects of the same disease unconnected with the puerperal state; but there are certain peculiarities which distinguish the disease from ordinary cases of acute mania, the chief difference being that P. M. is essentially a disease of exhaustion and not of inflammation. The symptoms are most accurately and graphically described by Dr. Rambotham as follows:—'In P. M. there is almost always, at the very commencement, a troubled, agitated, and hurried manner, a restless eye, an unnaturally anxious, suspicious, and displeasing expression of face; sometimes it is pallid, at others more flushed than usual; an unaccustomed irritability of temper, and impatience of control and contradiction; a vacillation of purpose or loss of memory; sometimes a rapid succession of contradictory orders are given; or a paroxysm of excessive anger is excited about the merest trifle. Occasionally one of the first indications will be a sullen obstinacy, or listlessness, or stubborn silence.' In cases where there is no hereditary predisposition, the prospect of recovery is favourable. 'Within three weeks,' says Dr. J. B. Tuke, 'or more frequently earlier, the mania gradually subsides, and is replaced by a state of dementia, generally accompanied by delusions, which almost invariably assume the form of mistaken identity. These gradually disappear, leaving a haziness of apprehension, and a state suggesting the idea of awaking from a dream. The patient can now generally be induced to work, and otherwise employ herself. From that moment you may look with almost certainty to her recovery.'

Puerto Bell'o, a port in the United States of Colombia, has an excellent harbour, which was discovered and named P. B. by Columbus in 1502. The town dates from 1584, and was a

place of much importance till 1739, when it was bombarded and taken by Admiral Vernon. Since then it has decayed, and its present pop. does not exceed 1300.

Puerto Cabell'o, a seaport of Venezuela, on an island in the Golfo Triste. It is the outlet of a rich agricultural and cattle-raising country, and the port of clearance for the copper obtained from the rich mines of Aroa, the ore being shipped at the neighbouring port of Tucacas. The imports at P. C. in 1876 amounted in value to £1,078,495, and the exports to £1,535,757. The chief exports are cotton, sugar, indigo, coffee, cocoa, and hides. Pop. (1869) 12,000.

Puerto de Santa Mari'a, commonly called *El Puerto* ('the port'), a seaport of Spain, province of Cadiz, in a richly productive district, on the Bay of Cadiz, and at the mouth of the Guadalete, 9 miles S.W. of Xeres by rail. It is the chief place of export for the Xeres wines, and characteristic of the town are the Bodegas in which the wine is stored, lofty buildings with very thick walls, pierced by narrow apertures. The Calle Larga, about a mile long, is the finest street, and the town is now girt by beautiful promenades. P. supplies drinking water to Cadiz, with which place it has communication three times daily by steamer. The May bull-fights of P. are among the most celebrated in Spain. In 1874 the total export of wine was 2,036,006 gallons, of which 1,126,461 were to England, including 835,401 to London. P. also manufactures leather, soap, hats, brandy, and liqueurs. Pop. 17,300. P. is the *Portus Menesthei* of the Romans.

Puerto Principe, a town in Cuba, W. Indies, 10 miles inland from its harbour, Las Nuevitass (on the N. coast of the island), but connected with it by railway. It was originally founded by Velasquez (1514) close by the sea, but has been thrice removed further inland. Pop. 30,000. Las Nuevitass exports tobacco, sugar, and molasses.

Puerto Rico, a Spanish island in the W. Indies lying E. of Hayti, and belonging to the group of the Great Antilles. It has the form of a parallelogram, and is 100 miles long by 40 broad. Area 3550 sq. miles, estimated pop. (1877) 635,000, rather more than half of whom are whites. (See *Consular Report*, 1877.) The interior of the island is occupied by a broad mountain mass with an average height of 1600 feet, but the highest summit of which rises to 3686 feet. On the S. and E. the mountains descend with steep slopes to the sea, but on the W. and N. the descent is much more gradual, and there is a fertile plain 5 to 10 miles wide between their bases and the sea. From the central chain many spurs run N. and S., separated by fertile valleys, which are abundantly watered and well wooded. Many small streams flow from the central watershed on all sides, of which the chief are the Manati, Loisa, Tiabajo, and Arecibo on the N. The soil is remarkably fertile, and the higher districts are well suited for European products. The climate is healthy, and more favourable for Europeans than that of any other of the W. Indian islands. The principal crops are sugar, tobacco, coffee, and cotton, of which the finest qualities are produced. Cattle and sheep are also extensively reared. P. has great commercial activity, through the ports of San Juan, Ponce, and Mayaguez, in spite of heavy taxes and obstructive customs regulations. The means of communication within the island are still of the worst description, and public works are almost unknown. In September, 1876, the island was visited by a severe hurricane, which did much injury to property and destroyed many of the crops. For some years previous to 1876, severe droughts have materially interfered with the productiveness of the island, especially in the rich Guayama and Ponce districts. P. is independent of imported labour, with its vast population. Slavery is now quite extinct, the three years' term of enforced contract for the *libertos*, or freed slaves, having expired in April 1876. The relative wealth of P. may be seen by the fact that while its area is less than one-sixth that of Ceylon, it produces two-thirds as much; and though considerably less than Jamaica, it more than doubles it in the value of its products.

The total value of its exports in 1876 was:—Sugar, £988,834; molasses, £184,991; coffee, £1,178,949; tobacco, £197,157; cotton, £3179; hides, £13,702; rum, £498; cattle, £71,810; fruit, £2927; wood, £4032; total, £2,646,077. The total value of the imports for the same year cannot be ascertained, as they are included in those of Cuba. In 1876 there entered its ports,

in the direct trade from and to Great Britain and the British colonies, 143 vessels of 18,858 tons, with cargoes estimated at £199,468; and cleared 116 vessels of 18,577 tons, with cargoes valued at £259,330; and in the carrying trade in British vessels from and to other countries, there entered 173 vessels of 35,707 tons, and with cargoes valued at £89,112; and cleared 214 vessels of 41,377 tons, and cargoes with value estimated at £264,836.

P. was discovered by the Spaniards in 1493, and has since remained uninterruptedly under their rule. The government is administered by a captain-general, with an adviser for civil affairs. Police and municipal affairs are subject to two courts of Cabildo, and in each of the seven departmental towns is an alcalde mayor.

Puff Adder (*Viper* or *Clotho arietans*), a species of *Viperine* snakes, belonging to the family *Viperidae*, and distinguished by its habit of inflating the skin of the neck when irritated or alarmed. It occurs in S. Africa, and attains a length of 4 or 5 feet. The head is short, flattened, and even broader than is usual in the *Viperidae*. The P. A. is of a brown hue variegated with darker patches, and with white markings. It is a deadly reptile, and lies concealed amidst sand with its head protruding, but is said to be readily killed by oil of tobacco or tobacco-juice.

Puff Ball, from resemblance to a powder-puff, is a name that has been adopted for a genus of Fungi called *Lycoperdon*. *L. giganteum*, the giant P. B., has in the young state a soft and smooth outer covering like kid-leather, becoming a dingy olive when old. It occurs locally in pastures, attaining a very large size; and when quite young is one of the best fungi to eat, if cut into slices and fried. The dry mass of threads and spores is used as a styptic, and the fumes have the effect of chloroform. The genus is represented abundantly in most countries, *L. calatum*, or the collapsing P. B., and *L. gemmatum*, the warted P. B., being the most common in Britain.

Puff Bird. See BARBET.

Puffendorf, Samuel, was born at Chemnitz, in Saxony, January 8th, 1632. The son of a Lutheran clergyman, he studied theology and afterwards law at Leipsic, and in 1656 repaired to Jena, where he devoted himself to the study of the Cartesian philosophy, under the influence of Erhard Weigel. From Jena he went to Copenhagen as tutor in the family of the Swedish ambassador. At Copenhagen he occupied his leisure in the composition of a work on general law, to combine the principles of Grotius, Hobbes, and others with discussions of his own, and the result was the *Elementa Jurisprudentiæ Universalis*, published at the Hague in 1660. This book, harsh in style, but original and profound, was dedicated to the Elector-Palatine Karl Ludwig, who created at Heidelberg a chair of the law of nature and of nations, placed Puffendorf in it, and entrusted him with the education of his son. P.'s lectures drew crowds, and revived the languishing prestige of the University. His next work was *Severini a Monarchano De Statu Imperii Germanici* (Geneva, 1667), in which he severely criticised the constitution of Germany. It was quickly translated into the principal European languages, and was forbidden circulation in Austria, where it was burned by the hangman. P.'s greatest work followed, *De Jure Naturæ et Gentium*. This was published in 1672 at Lund, whither he had betaken himself two years before to avoid German persecution. Subsequently the King of Sweden appointed him Councillor of State and royal historiographer, and he removed to Stockholm. Of his other works only two are ever referred to now—*Commentarii de Rebus Suecicis ab Expeditione Gustavi Adolphi usque ad Abdicationem Christianæ* (Utrecht, 1686); and *Commentarii de Rebus Gestis Frederici Wilhelmi Magni, Electoris Brandenburgici* (Berlin, 1695). P. died October 26th, 1694, at Berlin, where he had latterly lived in the court of the Elector of Brandenburg. The best edition of the *De Jure* is that of Leipsic (2 vols. 1744). There is an English version by Kennet (Lond. 1749); but Barbeyrac's French translation (Amsterdam, 2 vols. 4th, 1712), with notes, is most used.

Puffin (*Fratercula* or *Alca arctica*), a species of *Natatorial* or swimming birds, belonging to the *Alcida* or auks, and common on many British coasts. It attains a length of 13 inches, and breeds in April and May. The colour is a general black or very dark brown variegated with white. The wings

are represented by mere rudiments, but although useless for flight they are serviceable in swimming and diving. The P. lays a single egg of white colour, the egg being deposited in some deserted rabbit-burrow. The beak of the P. is large, and somewhat ungainly. Hence the name of 'Coulter Neb' applied in Scotland to this bird from the resemblance of the bill to the 'coulter' of a plough. As in other auks, the legs in the P. are placed far back on the body, so that in a sitting posture the bird appears erect.

Pug Dog, a variety of dogs usually kept as pets, notable for the breadth of the muzzle and for the black snout. The hair is short, and in pure-bred dogs is of a yellowish colour mixed with black. Pug dogs resemble the bull-dogs in appearance. They are as a rule of gentle disposition and frolic with children. Foreign species of P. D. may have long silky hair.

Pughe, William Owen, born at Llanfihangel-y-Pennant, in Merionethshire, August 7, 1759, at the age of seventeen came to London, where he found a patron in Owen Jones (q. v.). With him he edited the poems of Dafydd ap Gwilym (1789), and at his cost produced a Welsh and English Dictionary (2 vols. 1793-1803), a work, says Williams, 'ruined by hobby-horsisms, a horrid cacophony, and a barbarous orthography.' P. also wrote a *Cambrian Biography* (1803), translated into Welsh the *Paradise Lost* and other poems, and was editor of the *Cambrian Register* (1796-1818) and a Welsh magazine, *Y Greal*. He was a Fellow of the Society of Antiquaries, a D.C.L. of Oxford (1826), and one of Joanna Southcott's 'four and twenty elders.' In 1806 he returned to Wales, and died at Talylylyn, near Dolgelly, June 4, 1835.

Pu'gilism (Lat. *pugilatus*), fighting with the fists for money, according to the rules of the English prize-ring. Ancient pugilists fought with the cestus, strips of leather wound round the fist and the lower part of the arm, and sometimes with knobs of metal over the fist. The right arm was chiefly used to strike, and the left to ward off blows. Wrestling was not allowed. For many centuries the fist has played a leading part in single-handed encounters in England, but it was in the reign of George I. that P. developed the extraordinary and widely-extended popularity which characterised it for a century and a half. Broughton, for eighteen years champion of England, laid down about 1740 regular rules for P., in order to secure fair-play, which have not been greatly altered since. He is also said to have invented boxing-gloves. Jackson, champion in 1795, is esteemed as the most scientific boxer on record, and his classrooms in Bond Street were thronged with the golden youth. Lord Byron and Shaw the Life Guardsman among others first learned to use their fists under this master, who insisted as necessities of good boxing upon personal contempt of danger and self-confidence, accuracy in judging distances when striking, and great activity of limb as well as arm. The Regent was a warm patron of the 'noble art,' and the allied sovereigns, as well as the Emperor Nicholas were entertained on their visits to this country with exhibitions of this national sport. See article BOXING. But about twenty years ago the ring degenerated into a thoroughly vile state, and this brutal amusement is now viewed with such thorough aversion, that no prize-fight could take place without prompt and severe punishment. Professional pugilists, as may be imagined, are of a low class and character; and though the training they are obliged to undergo is of the most healthful description, they are exceptionally short-lived. With the stakes, sometimes very high in amount, which they win, they frequently retire to start public-houses, or to take chairs in back parlours where fisty encounters form the amusement of a 'Harmonic' evening. The ring has an extensive slang peculiar to itself, and its members are familiarly known as chickens, crushers, &c., by their admiring votaries. See Egan's *Boxiana*, or *Sketch of Ancient and Modern P.* (5 vols. Lond. 1818), *Fistiana* (Lond. 1863), *American Fistiana from 1816 to 1873* (New York, 1876). *Bell's Life*, London, and Wilkes' *Spirit of the Times*, New York, are the principal pugilistic papers in this country and America, and in their columns long and detailed accounts of all the great matches are given.

Pugin, Augustin, an architectural draughtsman, born in France in 1762, came to London after the Revolution, and was engaged for some time in the office of Nash the architect. He afterwards opened an architectural studio and school. P. published a number of works which did much to develop a widespread

taste for medieval architecture in this century; e.g., *Specimens of Gothic Architecture* (114 plates, 1821-23), *Architectural Illustrations of Normandy* (1825-28), &c. He died December 19, 1832. — **Augustin Welby Northmore P.**, a distinguished architect, son of the preceding, born in London, March 1, 1812, was educated at Christ's Hospital. Possessing a decided genius but erratic temperament, he became a proficient in various kinds of artistic work, and led a roaming life till 1834, when he joined the Roman Catholic Church and became one of its most devoted adherents and ablest adorners. His treatise on *Gothic Furniture and Iron and Brass Work* appeared in 1835. Such works as *Contrasts* (1836), *True Principles of Pointed or Christian Architecture* (1841), *Apology for the Revival of Christian Architecture* (1843), were published at the time of the great Tractarian movement, and his eloquent advocacy of Gothic architecture caused his services to be eagerly sought throughout the country. He refused, however, to lend his ecclesiastical services except to those of his own communion. He designed a vast number of Roman Catholic churches and buildings, including five cathedrals. Among his secular designs, the internal mouldings, fittings, furniture, and decorations of the Houses of Parliament hold a high place. He published a *Glossary of Ecclesiastical Ornament* in 1844 and a work on *Floriated Ornaments* in 1849. He served as a juror in the Great Exhibition of 1851. His heculean labours and probably his religious asceticism brought on an attack of mental aberration in 1852, and he died at Ramsgate, 14th September of that year. See *Recollections of A. W. N. P. and his father A. P.* by B. Ferrey (1861). — **Welby P.**, eldest son of the preceding, born in 1834, succeeded to his father's practice, and is well known as the architect of St. Michael's Priory, Belmont; the church of St. Peter and Paul at York; the magnificent mansion of Scarsborough Hall, Lancashire, &c. For the erection of the church of Notre Dame de Dadezeille he received from the Pope the Order of St. Sylvestre. He died at Ramsgate, 5th June, 1875.

Pulci, Luigi, a famous Italian poet, was born at Florence 3d December 1431. He enjoyed the friendship of Lorenzo de Medici and Poliziano, and produced his best work *Il Morgante Maggiore* (Ven. 1481) at the bidding of Lorenzo's mother, Lucrezia Tornabuoni. It is a mock-romantic epic in twenty-eight cantos on the Quixotic deeds of Rinaldo and the giant Morgante. P. also wrote a number of sonnets. He died at Florence in 1487. His poems are written in a pure and rich Tuscan, but their versification is harsh and unequal. The best edition of *Il Morgante Maggiore* is that published, with a biography, at Florence 1732 and Milan 1806. — P.'s two brothers, **Bernardo** and **Luca**, have also made themselves known by their poetical efforts, the former by an elegy on the death of Cosmo de Medici and a poem on the passion of Christ; the latter by a pastoral romance, *Driadeo d'Amore* (Flor. 1479), and an epic romance, *Il Cirisso Calvaneo* (Flor. 1490), which was probably the first in the Italian language.

Pulex. See FLEA.

Pulicat (Palicat), Lake of, an extensive inlet of the sea, or salt-water lake, between the districts of Chingleput and S. Arcot, on the Coromandel or E. coast of the Madras Presidency, British India. The lake is 33 miles in length from N. to S., and 11 miles in breadth where widest; it receives the drainage of 6700 sq. miles. It contains several large islands, on one of which is the town of P., often mentioned in the history of the wars in the Carnatic. An important line of water communication leads through the lake into the district of S. Arcot. There is a good anchorage 2 miles off the sandy beach that separates it from the sea.

Pul'kova, a village 9 miles S. of St. Petersburg, the seat of the Imperial Nikolai Observatory (founded in 1838), whose valuable library contains an almost complete collection of the MSS. of Kepler. P. lies at the foot of the P. mountains, which slope steep down to the Neva valley, and afford a magnificent view of St. Petersburg. Pop. 600. See Piazz Smyth, *Three Cities in Russia* (2 vols. Lond. 1862).

Pulley is a simple machine consisting of a wheel movable about an axis, and having a groove cut in the circumference, over which a cord passes. The axis is supported by the *block*, which may be either fixed or movable. A single P. serves

merely to change the direction of motion; but if the cord is passed under a second P. and then fixed to the block of the first, a certain *mechanical advantage* is gained, in virtue of which a mass may be raised by the action of a force less than the weight of the mass. In this particular case suppose the upper P. fixed, and a mass *M* attached to the free extremity of the cord. Let also a mass *W* be attached to the lower P. It is required to know what relation must exist between *M* and *W*, so that there may be equilibrium; it being postulated that the system is frictionless. There will be equilibrium when the work which *M* would do in falling through a certain height is equal to the work done upon *W* in raising it through that height through which the lower P. moves when the free extremity of the cord is depressed through the former distance. Now, if the lower P. is raised through, say, one inch, each segment of the cord connecting it to the upper P. is shortened by the same amount, therefore the portion of the cord going round the pulleys is shortened by twice that amount, and therefore the free extremity falls through a distance of two inches. But the work which P. does is the product of the weight of *M* into the height through which it falls; and the work done upon *W* is the product of its weight into the height through which it is raised, and this height is, as we saw above, equal to *twice* the former height. Hence, for equilibrium, the weight of *M* : weight of *W* :: 1 : 2 or the weight of *W* = twice the weight of *M*. By such an arrangement, then, it is possible to balance one force by another half its value; and by exerting a slightly greater force than the latter, it is possible to raise the former. By increasing the number of pulleys, the mechanical advantage is increased. There are various ways of arranging pulleys, which are known by special names and are applied to special purposes; but in all cases the advantage gained may be theoretically calculated by the application of the principle of work done. Practically, of course, the rigidity of the rope and the friction of the bearings considerably diminish the mechanical advantage. The various modifications usually known as systems of pulleys are given in detail in all text-books on elementary mechanics.

Pulmonaria, Pulmonifera, names applied in zoology (1) to the higher group of the *Arachnidans*, including the spiders and scorpions which breathe by means of *pulmonary sacs* or *lung sacs*, and (2) to the section of the class *Gasteropoda*, represented by the snails and slugs, which breathe air directly from the atmosphere. Air is admitted to the pulmonary sacs of the Arachnidans by apertures called *stigmata* or *spiracles*; and by a special aperture to the pulmonary sac or chamber of the Gasteropods.

Pulo Nias, the largest of a chain of islands lying off the W. coast of Sumatra. Area, 2751 sq. miles; pop. estimated (1878) at 500,000. The surface is mountainous, rising in the S. and S.W. to 2000 feet. The chief rivers are the Modyjeja on the N., the Solu and Idanoi on the E., and the Moioo and Nojo on the W. Earthquakes are frequent. The temperature ranges from 68° to 75° Fahr. The products are maize, sweet potatoes, sago, rice, and cocoa-nuts. The Dutch E. India Company in the 17th c., and the English in 1820, concluded commercial treaties with Nias chiefs, and in 1857 the whole island was taken possession of by the Dutch Government, who have yet (1878) only one fixed settlement therein—viz., at Gunong Sitoh on the E. coast. See Verbeek and Nagel in the *Jaarboek van het Koninkrijk in Ned. O. Indië* (1874 and 1876).

Pulo-Penang. See PENANG.

Pulpit (Lat. *pulpitum*, Gr. *logoson*) in Greek and Roman theatres was the part of the stage nearest the orchestra, and elevated above it, from which the actors spoke. In the Christian Church sermons were first delivered from the altar steps, and this place was named P. This name was next given to the elevated stage in churches, monastery-refectories, cloisters, &c., formerly in the first always placed in the nave, attached to a wall, pillar, or screen. Of the ancient wooden and stone pulpits in England, the former are usually polygonal, having panels adorned with feathering, tracery, &c. After the Reformation the number of wooden pulpits here was immensely increased. The pulpits of Continental churches are often very large and most elaborately adorned with architectural and sculptured ornaments, especially the crucifix.

Fulque, a species of beer or fermented liquor prepared in Mexico and Central America from the juice of the *Agave Americana* and allied species. The juice is obtained in abundance by removing the flowering stem when it is on the point of expanding. P. is not a pleasant beverage to those unused to its peculiar smell and flavour. A spirit is also distilled from it.

Pulse, the name applied to the movement of the *arteries* or bloodvessels originating from the left ventricle of the heart, and carrying pure blood throughout the body. The muscular force of the left ventricle of the heart in propelling blood through the vessels is somewhat impeded by the capillary circulation—that is, the jet or flow of blood cannot pass at once and directly onwards into the smallest bloodvessels. Hence part of the force is expended on the elastic and contractile walls of the arteries, with the result of producing the movements which constitute the P. of each bloodvessel. When the artery is affected by the forcible contraction of the left ventricle, it increases in both length and diameter, but owing to the muscular and contractile structure of these walls the bloodvessels recoil after the ventricular contraction has passed away. The P. calculated as arising from any one particular part of the heart is not perceptible at the same time in all the arteries. The carotid P. in the neck, for instance, will be felt before the radial at the wrist, and the radial in its turn before the P. say in the dorsal artery of the foot. The differences in the time of pulsation of the arteries naturally vary with the distance from the heart. Probably, however, the greatest difference between the P. of any two arteries is not greater than the one-sixth or one-eighth of a second. By means of an instrument called a *sphygmograph*—consisting of a lever moved by the P. and of a clock-work arrangement causing a card to move whilst a second lever is made to trace a line (corresponding to the P.) in the card—the graphic 'form' of the P. can be ascertained. A healthy P. gives a tracing in which a short firm up-stroke exists with a slanting but firm down-stroke. A wavering and indented down-stroke, on the other hand, would indicate a weak P. The P. is affected by the various circumstances which modify the action of the heart; hence the value of the P. as a symptom of disease. Age, sex, mental condition, disease, temperament, and even posture, influence the heart's action and produce variations in the P. In some persons the P. appears to exhibit constitutional peculiarities with which the sphygmograph has made us familiar.

Pulse (Lat. *puls*, Heb. *phul*), a pottage of meal and peas; but is now limited to the seeds of various *Leguminosae* cultivated for food. Of such, *Phaseolus* furnishes some of the most useful. *Cajanus* yields a P. in great and general esteem in India, forming in some districts the prevailing article of diet of all classes. *Dolichos*, *Labiab*, *Cicer*, and *Canavalia* also furnish important P. See KIDNEY-BEAN, CHICK-PEA, and PIGEON-PEA. The ordinary peas and beans may also be termed P.

Pultava, or **Poltava**, a government of S. Russia, bounded N. by Kiev, S. by Kherson and Ekaterinoslav, E. by Kharkov, and N. by Tchernigov. Area 19,261 sq. miles; pop. (1870) 2,002,118. P. belongs to the basin of the Dnieper, whose chief affluents are the Sula, Psiol, Vorskla, and (on the S. frontier), Orel. Except on the swampy flats on the left banks of the river the land is very fruitful, and yields abundant fruit, corn, tobacco, and pasturage for cattle. Seven per cent. of the surface is covered with forest.—P., the capital, on the right bank of the Vorskla, consists of an old part in the middle, with additions grouped around it in the form of a fan. It has a cathedral and twelve other churches. A monument commemorates the battle of 8th July 1709, in which Karl XII. of Sweden was decisively defeated by the Russians. The fair held at P. from the 20th to the 31st July is the third greatest mart for the internal trade of Russia. In 1871 the goods sold were valued at £2,448,800. Pop. (1870) 33,979.

Pultusk, a town of Russia, in the Polish government of Lomza, on the river Narev, 31 miles N. of Warsaw, has the castle of the Bishop of Plock, and a pop. of (1870) 7916. P. was (1703) the scene of a victory of Karl XII. of Sweden over a Saxon army under General Steinau, which was almost entirely taken prisoner; and here the French under Lannes, after a sharp action, compelled the Russians under Bennigsen to retreat (26th December 1806).

Puma, or Cougar (*Felis* or *Leopardus Concolor*), a species of Feline Carnivorous animals occurring in N. and S. America,

Puma.

and by some naturalists named the 'American Lion.' In general appearance the P. resembles a lioness. It has no mane, and its colour is reddish brown above and white below. The average length of the animal is from 6 to 8 or even 9 feet. It is stealthy in its habits, but seldom or never openly attacks man. It effects great destruction in sheepfolds, and climbs and swims with facility. By American farmers the P. is named the 'Panther,' or 'Painter.'

Pumice (Lat. *pumex*, orig. *spumex*, 'what is spit or spumed out'), the name of the light cellular ejections of a volcano. It is very porous, has a fibrous appearance, and is so light as to float on water. Being almost wholly composed of silica and alumina, it is much used for polishing and cleaning purposes. The chief localities where it is abundant are the islands of Lipari, Ponza, Ischia, and Vulcano, lying in the Mediterranean, to the N. of Sicily.

Pumpkin, or Pom'pion. See GOURD.

Pumps depend for their action upon fluid pressure. There are various kinds of P.—air-pump, suction-pump, force-pump, &c., named according to the purpose for which they are used, or the principle upon which they work. The structure of the air-pump is described under that heading. The ordinary suction pump consists of a hollow water-tight cylinder, in which a movable piston fits, provided with a valve opening upwards. At the lower end of the cylinder, which dips into a reservoir of water, is another valve, also opening upwards. The piston is worked by a convenient lever handle. Suppose, to begin with, that the tube contains only air. When the piston is pushed down, the increased pressure will force a certain quantity of air out by the only possible outlet, the valve on the piston. If the piston is now raised, the pressure of the air on the tube is diminished, and the constant atmospheric pressure exerted upon the external surface of the water in the reservoir forces water through the lower valve into the tube. This water once in cannot escape again, because the lower valve opens only upwards. A second down and up stroke of the piston is followed by the influx of more water into the tube; and at length, after several strokes have been given, the column of liquid reaches above the lowest position of the piston, which then raises this upper portion during its up stroke to the opening in the side of the tube by which the water escapes. The true agent in the suction pump is therefore the pressure of the atmosphere. The water in the tube rises simply because a partial vacuum is formed above it by the motion of the piston. If it were possible to form a perfect vacuum, the water would rise to a height of about 33 feet, since the pressure of the air can support a column of water that height. Practically, however, suction P. are useless for depths exceeding 24 or 25 feet; consequently for greater depths other methods must be adopted. The force-pump is employed instead. It differs from the suction-pump in having the discharge pipe entering *below* the piston, which has no valve. A valve opens upwards as before into the piston tube, and a second valve opens outwards into the discharge pipe. When the piston is pressed down, the compressed air is forced through this valve into the discharge pipe. When the piston is raised, water pours in from below to fill up the partial vacuum. When the piston is again forced down, this water is pressed out by the side valve into the discharge tube. By a succession of strokes as much water is forced into the discharge pipe as may be required. In both these simple P., it is evident that the water is discharged in a series of jerks. For many purposes this is objectionable; and to remedy this fault various schemes have been devised. In the simplest double action force-pump, half the water which in the single action pump would be wholly forced into the discharge pipe, finds its way into the tube above the piston partially filled by the piston rod. When the piston is raised this quantity of water into the discharge pipe. In this way water is being forced out

during both the up and the down stroke. There are many modifications of this principle, one of which, invented by Worthington of New York, merits special notice. In it the piston works horizontally in a chamber which is provided with a number of ingress and egress valves. Whatever the position of the piston, the chamber is divided into portions, which, during the reciprocating motion of the piston, are varying continuously in volume. The portion at that end towards which the piston is advancing at any instant is of course diminishing in volume, and the water in it, therefore, is being forced out by the egress valves, its ingress valves being closed. At the same time, the other portion, which is increasing in volume, is being filled, because of the diminishing pressure, by water pouring through the ingress valves from the reservoir. This water during the return stroke is then forced out, while the other portion of the chamber is filling. The old-fashioned hand fire-engine is a double action force-pump. It consists of a cylinder, in which the shaft CD works with a rocking motion. When C is moving down, the valve *c* is shut, and the water in E escapes by the valve *a*. D is at the same time moving up, and forces the water in the upper portion through the discharge-pipe B. Simultaneously the pressure is diminishing in F, and therefore the valve *d* is forced open by the intruding water from A. During the reversed stroke *a* and *d* are closed, and *b* and *c* are open, and water is impelled through B as before. This modification is due to Bramah. In the *centrifugal* P. of Appold, Gwynne, Bessemer, and others, water is introduced at the centre of a wheel which rotates in a cylinder; and by this rotatory motion the fluid is driven out to the circumference along the vanes of the wheel, and thus gains sufficient tangential velocity to impel it along the discharge pipe. In all P. there is always great loss, arising mainly from the velocity of the liquid and the friction of the bearings. The Archimedian Screw (q. v.) is a kind of pump which works by gravitation.

Pumps.

Pun (variously derived from Fr. *pointe*, 'a point or witticism,' and Old Eng. *punian*, 'to bruise') is defined by Addison (*Spectator*, No. 61) as 'a conceit arising from the use of two words that agree in the sound but differ in the sense.' It constitutes, according to Wendell Holmes, the crime of 'verbiage, i.e., violent treatment of a word with fatal results to its legitimate meaning, which is its life.' But though most good and great writers concur with him in reprobating this '*sottise des gens d'esprit*,' it has been indulged in at all times and by all manners of men. Aristophanes' comedies are only less full of *double entendres* than a modern burlesque; Cicero *bores* one with his everlasting jokes on *Verres*; Elizabeth, rallying *Burleigh* on his *burlesqueness*, remarked that he would make *less stir* in our realm than my Lord of *Leicester*; grave Puritans *baited* the Pope's *bull*; and Shakespeare, ever faithful to nature, makes some of his characters punsters, as others are liars and braggadocios. Even Dr. Samuel Johnson, although he said that 'the man who would make a P. would pick a pocket,' himself fell into the fault which he had often condemned in others, and was guilty of one P., and that of a very heinous character. Those who have a taste for criminal literature, and would read of the exploits of those deliberate and professional punsters, Sydney Smith, Hook, Hood, Montmaur, and the Marquis de Bièvre, may study Rowley's *Puniana* (2 vols. Lond. 1874) and L. Larchey's *Les Joueurs des Mots* (Par. 1866). Then, as an antidote, let them turn to pp. 12, 15, and 293 of Holmes' *Autocrat of the Breakfast Table* (new ed. Bost. 1877).

Pu'na, the name given in S. America to the bleak tablelands of Peru and Bolivia, whose elevation above the sea-level varies from 12,000 to 18,000 feet. Their surface is stony, and devoid of vegetation, while animal life is represented only by the condor and rare specimens of the vicuña. The *Despoblado*, or unpeopled region of Peru, called also the Black P., has an average breadth of 150 miles, and is crossed only by certain tracks or trails, which are strewn with the skeletons or desiccated bodies of men and

animals that have perished in traversing this inhospitable region. Caverns, and a few wretched huts of refuge furnish the only shelter from the piercing winds which sweep over these dreary plains. The lower P. of Bolivia supports a scanty Indian population.

Punch, a tool of steel for piercing holes in various materials, or for cutting out shapes or designs by percussion or pressure. In its simplest form, as used by blacksmiths and other operatives for perforating thin metal plates, the P. is a short piece of solid steel, with a flat point, and it is driven through the plate to be perforated by striking the head with a hammer, there being a hole in the anvil or other support directly under the plate to receive the pieces punched out. In many cases the P. has its lower end in the form of a hollow cylinder with cutting edges, adapted for cutting out wafers, lozenges, paper discs, &c.; while in others the end of the P. is shaped as a letter, number, or ornamental design. A saddler's or shoemaker's P. has lever arms like pincers or pliers. Powerful punching-machines, worked by hydraulic or steam power, are in use for perforating boiler-plates, &c., for the reception of rivets or screws, and in connection with these machines, Kennedy's new spiral P. has recently been introduced into this country. This P., instead of being flat-ended, has its point constructed in a helical form, which cuts with a shearing action; and experimental tests on the tensile strength of steel boiler-plates perforated with the ordinary flat P. and with the spiral P. have yielded results greatly in the favour of the latter. P. is also the name given to an instrument used by die-sinkers in forming duplicate copies of an original coin or medal die. See DIE-SINKING.

Punch, the principal character in the favourite puppet-show of *Punch and Judy*. The name, though perhaps crossed in its orthography with the English word *punch*, is probably a diminutive of the Italian *Policinella* or *Pulcinella*, which is said in Gallani's *Neapolitan Vocabulary* to have been called after Puccio d'Aniello, a buffoon of Acerra, whose eccentricities became a common subject for dramatic treatment in Naples, the character being made the medium of local and political satire. The original puppet *Policinella* had a face like the ancient comic mask, the nose being like the beak of a bird. His functions were similar to those of the Vice of the old moralities and the clown of later date. He was a roguish chatterbox and an amorous cynic. The drama of *Policinella* owes its origin to Silvio Fiddo, an Italian comedian, who about the year 1600 made P. the perpetrator of a domestic tragedy followed by supernatural retribution, in a play of a broadly farcical character. *Policinella* was originally straight and erect in body, but in his travels through France and England he lost much of his personal comeliness. From a young and joyous Don Juan he was transformed into an obese and humpbacked Falstaff, and on his appearance in this country he threw away the gay satire of Italy for the rough practical humour of England. In the reign of Queen Anne he became a public and highly popular character. The *Tatler* and *Spectator* frequently prattled about him. A letter in No. 14 of the latter, purporting to come from the sexton of St. Paul's, Covent Garden, complains of the show outside thinning the congregation. In addition to his own legitimate drama, he played as clown in many other puppet-shows. Since then he has been a perpetual pet of the nursery, and the acknowledged prince of puppets. Two men are usually engaged in the street exhibition, one carrying the theatre, and the other the box of puppets. The forefinger is used to move the head of the puppet, and the second finger and thumb the arms. A full account of the history of P., with the words of his *Tragical Comedy or Comical Tragedy*, taken from the lips of a famous showman by Mr. Payne Collier, with 24 illustrations by George Cruikshank, is published under the title of *Punch and Judy* (5th ed. 1870). A similar show has been popular in China for many years.

Punch is an intoxicating beverage, now much less frequently seen than was the case about the beginning of this century. It is composed of alcoholic liquor, hot water, and sugar, flavoured with acid fruit juices. For spirits, wine is sometimes substituted, sometimes both are used, and the beverage becomes a complex preparation like modern American 'drinks.' Rum P. is a staple beverage among sailors. Scotch 'toddy' is a form of P. made with whisky, generally, however, without any fruit juice being employed.

Punctuation (Lat. *punctum*, 'a point'), the art of dividing written composition into sentences and clauses by stops or points, so as to bring out the sense and relation of the words, and help the reader to a proper enunciation. A method of P. is said to have been devised by the grammarian Aristophanes (3d c. B.C.), but the present system was the invention of the early printer Manutius (q. v.). To him we owe the period, colon (Gr. 'limb'), semicolon, and comma (Gr. 'segment'), the marks of interrogation and exclamation, the parenthesis and dash, as well as the hyphen, apostrophe, and quotation marks, which are sometimes, though improperly, included in P. These points are used almost everywhere in the same manner, the chief exceptions being that in Greek a turned full-stop (·) supplies the place of the semicolon, which stands for the sign of interrogation, and that in Spanish the marks of interrogation and exclamation precede the sentence.

Pundit (*pandit*), the Indian title for a learned Brahmin, especially one who makes some branch of Sanskrit learning his special study, and teaches it. Study and instruction form one common religious duty, and the same word is applied to the student and the teacher. The P. is highly respected; he is abundantly supported by charity or endowments, and demands no remuneration. Some of the students of the Veda are able to repeat the whole by heart, numbering more than 10,000 lines; others apply themselves especially to logic. P. has, in some cases, become a proper name.

Punica. See POMEGRANATE.

Punishments of officers and soldiers in the army and navy are detailed in the Mutiny Act, the Articles of War, and the Queen's Regulations. The commanding officer has only the power of reprimanding a commissioned officer, who must be tried by a court-martial. He may be sentenced to death, degraded, or cashiered, or in the navy placed at the bottom of the list of officers of his grade. The men for minor offences may be admonished, imprisoned for short periods, undergo punishment drill or stoppage of leave and pay. For more serious offences, when they are tried by court-martial, they may be dismissed the service, imprisoned, or be sentenced to penal servitude, or death. The extreme penalty of the law takes the form of shooting if for an offence against discipline, or by hanging if for a heinous crime. Flogging has been abolished except when on active service in the army, but is still occasionally resorted to in the navy. A non-commissioned officer can only be reduced to the ranks and punished by sentence of court-martial.

Punjab (*Panjab*, 'the area between the five rivers,' cf. Doab), a province on the N.W. frontier of British India, bounded S. by Scinde and Rajputana, N. by the upper ranges of the Himalayas, E. by the river Jumna, separating it from the N.W. Provinces proper, and W. by the Suleiman mountains, which shut off Afghanistan; area, 103,748 sq. miles, of which only 34,438 are cultivated; pop. (1868) 17,596,752, of whom 53 per cent. are Mohammedans, strongest in the N.W. and W.; 35 per cent. Hindus, chiefly in the N.E. and E.; and 6 per cent. Sikhs, centering round Lahore and Amritsar. Ethnically the Juts or Jats (q. v.), supposed to be of Scythic origin, number more than three millions, the Rajputs nearly one million, Brahmans 800,000, Pathans (q. v.) or Afghans 700,000, Gujars 500,000. This is apart from dependent and feudatory states and the frontier tribes. The native states, of which the chief are Cashmere, Bhawalpur, and Pattecala, are 36 in number; estimated area, 104,000 sq. miles; pop. 5½ millions; revenue, £1,800,000; military forces, 50,000 men; tribute to British Government, £28,000. The frontier tribes, of whom the principal are the Swatees, Afreedees, and Wazirees, and who are all either Pathans or Beluchees, are estimated to number 130,000 fighting men. The P., as an administrative unit, under a Lieutenant-Governor of its own, is divided into 10 divisions, 32 districts, and 132 *tahsils* or subdivisions. This tract, however, is in every direction more extensive than the old province known to geography and to history. This latter was strictly limited to the area watered by the five rivers, the Sutlej, Beas, Ravi, Chenab, and Jhelum. But the kingdom acquired by conquest after the second Sikh war of 1849 extended across the Indus to the borders of Afghanistan, and N. up towards Chinese Tartary; while in 1858, after the Mutiny, a slice of Hindustan proper, including the capital of Delhi, was added to

the P. The climate is liable to extremes of heat and cold, and the rainfall is scanty. The soil is a vast expanse of alluvial clay and loam, everywhere covered or sprinkled with sand. Agriculture, therefore, is largely dependent upon irrigation, which is applied by the Persian wheel. Apart from the rivers and private canals, there were, in 1873-74, 991,000 acres irrigated; the total outlay by Government has been £1,827,000; and the net revenue (direct and indirect) £171,000, or more than 9 per cent. on capital. The chief Government canals are the Baree Doab and W. Jumna systems. The staple crops are—in the spring, wheat, barley, pulses, oil-seeds, vegetables, tobacco, and poppy; in the autumn, millets, maize, rice, cotton, sugar-cane, and indigo. Out of a total cultivated area of 19 million acres, nearly six millions were in 1874 under wheat, and more than four millions under *jowar* and *bajra*, the two kinds of millet. In Kangra district there were in the same year 28 tea-gardens, covering 3390 acres, and producing 526,000 lbs. The domestic animals are oxen, buffaloes, horses, camels, goats, sheep, and donkeys. The mineral products include iron, copper, antimony, gold, and lead; salt, saltpetre, and alum; building stone of all kinds, marble, slate, sulphur, petroleum, and coal. The total annual value of the manufactures is estimated at £5,300,000. The most important are cotton, silk, and shawl weaving; gold and silver lace, leather, iron, steel, jewellery, pottery, and glass. Careful statistics of all branches of trade are now collected. In 1874-75, the total imports were valued at £11,339,000, the exports at £5,612,000. The English piece-goods imported were alone valued at £7,000,000 sterling, of which much is redistributed from Delhi. The exports of grain of all kinds exceeded the imports by 131,000 tons; horns and hides were exported to the value of £1,043,000; *pashmina* or shawl goods were imported to the value of £233,000. There is a large transit trade with Central Asia, and also down the Indus to Kurrachi. The commercial centres are Delhi, Lahore, Multan, Amritsur, and Peshawur. Delhi has a pop. of 154,000, Amritsur 133,000, but Lahore with 98,924, the former capital of Runjeet Singh, is the seat of the British Government. In 1873-74 the imperial revenue was £3,458,000, of which about £2,000,000 came from land and £867,000 from salt; in addition, there were local receipts to the amount of nearly £1,000,000. The military force consists of 18,000 European and an equal number of native troops, with 97 guns under the commander-in-chief; and the P. frontier force of 12,000 men, maintained at a cost of £360,000, under the orders of the Lieutenant-Governor, for the control of the hill tribes. The police number 20,000 men, costing £300,000. There are altogether 1921 educational institutions, Government and aided, attended by 103,000 pupils, at a total cost of £124,000. The languages spoken are Hindustani, Punjabi, a dialect derived from the ancient Sanskrit, and akin to Hindi and Pushtu (q. v.), the language of the Afghan frontier, which has been ascertained to belong to the Iranian or Zend branch of the Aryan family. The length of roads, metalled and unmetalled, is 20,000 miles; of water communication, 2470 miles; and of railways, 687 miles were open at the close of 1875. Two important lines of rail are not yet (1878) finished—from Lahore to Peshawur, and from Multan to Kurrachi in Scinde. There are about 4000 square miles under the management of the forest department, the most valuable trees being deodara and other varieties of pine; in 1873-74 the receipts were £73,000, giving a net revenue of £13,000. The land settlement is made direct with the cultivators, grouped together in their indigenous village communities; the assessment is usually for a term of 30 years, and there are altogether about 2,000,000 cultivating proprietors, with recorded rights. The history of the P. is representative of the different races who have conquered India, and the plains between its rivers form the 'cockpit' of Hindustan. In 327 B.C. Alexander the Great advanced as far as the Sutlej, and the Græco-Bactrian dynasty founded by his general, Seleucus, which lasted till about 126 B.C., has left many remains. A Hindu dynasty was then restored, and the P. was at one time a stronghold of the Buddhists. In 1021 Mahmud of Ghuzni made Lahore the capital of a subject province; and the Mohammedans continued predominant, in successive waves of Tartar and Afghan conquest, until Runjeet Singh (q. v.) established a Sikh (q. v.) empire at the beginning of the present century. After his death, the recklessness of the *Khalsa* or Sikh army forced on a collision with the British; and after the second Sikh war, the P. was

permanently annexed, and the Maharajah Dhuleep Singh, the infant son of Runjeet, received a pension of £50,000 a year, which he now enjoys as a Christian country gentleman in Norfolk. A picked staff of civilians and military officers was chosen for the new administration, which has been of the most effective character. Even during the Mutiny of 1857-58 the civil population remained loyal throughout. The Bengal sepoys were either disarmed or promptly punished for rebellion, while the warlike Sikhs and Pathans reinforced the British army before Delhi. The chief names associated with this brilliant chapter in British annals are the Lawrences, Henry and John, Sir H. Montgomery, Sir H. Edwardes, Generals Nicholson and Abbot, Sir R. Temple, and Lord Napier. The P. is still administered as a non-Regulation province. It has recently (1878) been proposed to separate the outlying districts beyond the Indus, and form them into an independent frontier administration, together with the adjoining province of Scinde. See *Annual Blue Books on the Moral and Material Progress of India* (London); *Annual Administration Reports of the P. Government* (Lahore); Cunningham's *History of the Sikhs* (Lond. 1853); General Cunningham's *Ancient Geography of India* (Lond. 1874); *The Rajas of the P.* by Mr. Lepel Griffin (Lahore, 1870); *Handbook of the Manufactures and Arts of the P.* by Mr. Baden Powell.

Punjnud, the name given to the stream which conveys the united waters of the Punjab into the Indus. These rivers are the Sutlej, Beas, Ravi, Chenab, and Jhelum. The total course of the P. is about 60 miles, in a S.W. direction, and it falls into the Indus opposite Mittunkote.

Punkah, the Indian name for a fan, derived from a Sanskrit word, meaning 'feather.' It is of two kinds—(1) The hand-fan, which is greatly in use among natives, and is not made to close like its European copy. It is sometimes highly ornamented, of peacocks' feathers, with a gold or silver handle, and it figures largely in state ceremonials. (2) The machine for cooling the air of rooms, universally used by Europeans. This consists of a framework fixed in the ceiling, from which depends a fringe or curtain. The framework moves on hinges, being set in motion by a rope pulled by a person outside. One of the grievances of Indian life arises from the fact that the 'P. puller' will fall asleep during the hot nights.

Punnah (*Pand*), the capital of a native state of the same name in Bundelcund, Central India, 110 miles S.W. of Allahabad. It is handsomely built of sandstone along the side of a tank, and contains many Hindu temples.—The state of P., which lies between the N.W. and the Central Provinces, has an area of 2555 sq. miles; pop. 183,000; revenue £50,000. The country is a tableland among the Vindhyan Mountains, and yields iron and diamonds.

Punt (Dutch *pont*, Fr. *ponton*), a small open boat of oblong form, flat-bottomed, and usually with square ends. It is mainly used in shallow waters, as on rivers and marshes, and is generally propelled by poles.

Pu'pa (Lat. 'a girl'), the second stage in the *metamorphosis* of insects. The P., or *chrysalis*, as it is also named, is quiescent and enclosed in a *cocoon* or in the larval skin. In some insects, however (e.g., grasshoppers, &c.), the P. is not enclosed, but active, and only differs from the adult by not having wings. The period during which insects remain in this state varies considerably.

Pu'pil. See AGE.

Pu'pil, Artificial, the name applied to an arrangement effected by oculists, in cases of disease of the eye, or where the vision is from whatever cause imperfect, with the view of rendering the pupil capable of adjusting itself perfectly to the admission or seclusion of light-rays. The formation of an A. P. is attended with difficulty. The pupil itself is the aperture in the *iris* (see EYE) through which the light-rays pass, the muscular fibres of the iris contracting or expanding so as to vary the size of the opening.

Pupilage, or Pupillarity. See AGE.

Pu'pils Protection Act. This is a Scotch 'Act of Sederunt' (see ACTS OF SEDERUNT), regulated and amplified by 13 Vict. c. 51, for the protection of the property of pupils (see AGE), and of those absent from Scotland, or of mental incapacity

(see CAPACITY, LEGAL). Under these Acts, every *Judicial Factor* (q. v.) must give security for his pecuniary transactions, and for performance of his general duties, regarding the estate of his pupil.

Pupil-Teachers are boys and girls in primary schools who are, in the first place, pupils, but who are also partly occupied in teaching. The English Elementary Education Act of 1870 requires that P.-T. be not less than thirteen years of age; that they be duly presented for examination to the inspector; and that they acquire certain certificates. Their engagement is for five years, at the end of which time they may be admitted into a training college. Their salary for the first year is about £10, and is increased at the rate of some £2, 10s. yearly. In 1874 there were in England and Wales 27,321 P.-T.

Puppets (Lat. *pupus*, 'a child,' Fr. *poupée*, 'a doll'), stage figures usually made of wood, worked by the hand or by wires or other mechanism. Their use is doubtless as old as the drama itself. The fantoccini (Ital. *fantino*, 'an infant') or puppet shows of Italy were very famous, and it was probably from this country that they were introduced into France and England. The old English name for puppet is motion, and motion plays were common before the institution of the regular theatre. Ben Jonson in his *Bartholomew Fair* makes Lanthorn Leatherhead convert the story of Hero and Leander into a motion play. From this writer's works we infer that two kinds of puppet shows existed at his time, one with dialogue and the other in dumb show. Even when theatres were firmly established in London, puppet shows continued to be held with *éclat* in Fleet Street and Holborn, where they frequently parodied the efforts of the legitimate drama. Old Testament stories and the lives of saints furnished a favourite field for puppet display—*David and Goliath*, *Noah*, and *The Prodigal Son* were extremely popular shows, while that of *Nineveh with Jonas and the Whale* is mentioned by Jonson and twenty other authors. The unfortunate P. suffered persecution like their friends the actors at the hands of the Puritans. Goldsmith refers to the show of *Solomon's Temple* in *She Stoops to Conquer*. Dr. Johnson declared that the play of *Macbeth* might be acted satisfactorily by P. alone, and a man named Henry Rowe acted upon his suggestion with some success. Puppet shows on scriptural subjects were long in vogue in Germany, where Dr. Faust was also a favourite hero. Goethe in the opening chapters of *Wilhelm Meister* makes the hero weary his beloved Mariana with a recital of his delight in P. to which he owed his earliest dramatic instincts. Towards the end of the 16th c. there were popular marionette (or puppet) theatres in France, and so late as the 18th c. they were a favourite amusement to the aristocracy of that country. Under this name of Marionettes (q. v.) some very ingenious puppet exhibitions are still made. There is a history of puppet plays in England in Cruickshank's *Punch and Judy* (5th ed. 1870).

Purāṇa (*Pitrāṇā*, from a Sanskrit word, meaning 'before, old'), the especial designation of a class of religious works in India, which rank second to the Vedas, and form the basis of the popular belief of the Hindus at the present day. They are 18 in number, with as many more minor or upa-puranas; and though they refer to, and evidently embody earlier works, none of them can be traced back in its present form for more than 1000 years. They are divided into three classes, each containing six books: (1) The *Rājasa P.*, relating to Brahma; (2) the *Sattvika P.*, relating to Vishnu, the most important class; (3) the *Tamasa P.*, relating to Siva. As opposed to the Vedas and other more ancient Sanskrit writings, they represent an exoteric teaching for the general community, and aim at spreading, in a sectarian form, the worship either of Vishnu or Siva. Their invariable form is that of dialogue, in which the chief speaker is usually Lomaharshana, who is represented as conveying the doctrines of his preceptor Vyasa, the supposed arranger of the Vedas and author of the Mahabharata. The earliest P. is assigned conjecturally to the 9th c., the latest to the 17th c. A.D.; but to the Hindus all alike are shrouded in the remotest antiquity. See *Collected Works* of W. W. Wilson (vols. iii. and vi. Lond. 1864), and Dr. John Muir's *Original Sanskrit Texts* (5 vols. 1858-70).

Purbeck, Isle of, the name given to the district of country which lies to the S. of Dorsetshire, and is bounded on the N. 260

by the river Frome and Poole Harbour. In early times it was a royal deer forest. At the present day it is of great interest to geologists. See **PURBECK BEDS**.

Purbeck Beds constitute the upper members of the Jurassic or Oolitic Period, and are so named from the locality of greatest development. They overlie the Portland Beds, attain a thickness of 290 feet, and consist of argillaceous limestone alternating with schistose marl. The fossils are mainly freshwater, comprising cycads and conifers in the lower strata, and abundant and characteristic shells in all. Groups of marine shells, resembling the Kimmeridge and Portland fossils, occur near the base of the middle strata, thus indicating a gradual change of conditions towards the close of the Oolitic Period. Near the top, an impure freshwater limestone known as Purbeck Marble is quarried. It was formerly used for decorating the interior of churches, its ornamental appearance when polished being derived from the presence of *Laludina* shells in great abundance.

Purcell, Henry, one of the greatest of English composers, born in London in 1658, was the son of a gentleman-musician attached to the court. As a chorister in the Chapel-Royal, he was trained by Captain Cook and Pelham Humphrey, and he seems to have had some lessons from Dr. Blow. He became organist of Westminster Abbey at the age of eighteen, and during the next few years produced many anthems and choral works, which attained amazing popularity. About 1690 he began to write for the stage. Among his best compositions in this department were his music to *The Tempest* (1690), *King Arthur* (1691), and *The Indian Queen* (1691). One of his last works was a *Te Deum and Jubilate* (1694), a magnificent hymn. He died of consumption, 21st November 1695, and was buried under the organ at Westminster Abbey. A large collection of his songs and duets (*Orpheus Britannicus*) was published in 2 folio vols. after his death. Many of his odes, glees, catches, &c., are still favourites. An original and vigorous musician and thoroughly English in style, he was our first great song-writer. See Essay prefixed to a collection of his church-music by V. Novello (1826-36).

Purchas, Samuel, born at Thaxted, Essex, 1577, was educated at St. John's College, Cambridge, and in 1604 was appointed vicar of Eastwood in Essex. This position he resigned to his brother, and proceeded to London with a view to literary work. Receiving the rectory of St. Martin's, Ludgate, and being also made chaplain to Archbishop Abbot, he gave his whole attention to the collection of works of travel, and in 1613 he produced a thick folio entitled *P. his Pilgrimage, or Relations of the World, and the Religions observed in all Ages, and Places discovered from the Creation unto this Present*. A greatly enlarged edition, with maps by Mercator and Hondius, appeared in 1625. More than 1300 authors were laid under contribution for this work. In 1616 the manuscripts of Hakluyt fell into the hands of P., and continuing Hakluyt's plan, P. in 1625 produced four folio volumes—*Hakluytus Posthumus*, or *P. his Pilgrimes*. Vols. iii. and iv. relate to America, and contain the earliest narratives of English explorers of the W. P. is at pains to make it clear that the *Pilgrimage* is his own work, as to plan and language, while the *Pilgrimes* is simply compiled in the words of others. P. was buried in St. Martin's, Ludgate, 30th September 1626. Some say that he died in prison under debt contracted in the publication of his valuable books; but, according to Anthony Wood, he died in his own house. P. also wrote *Microcosmus*, or *the History of Man* (1619), and *The King's Tower and Triumphant Arch of London* (1623). He is a quaint, garrulous, metaphorical writer; and his immense stores of knowledge have been very useful to later authors.

Purchase, in English law. If an estate come to a man from his ancestor without writing, that is a *descent*; but when it comes by will or gift, that is a *P.*

Purchase System, in the British army, was the arrangement according to which promotion of officers was for many years regulated. It was of ancient standing, though not formally recognised till the reign of Queen Anne, and was finally abolished by royal warrant of 20th July 1871. Under this system first commissions were given to gentlemen whose names were on the commander-in-chief's list, and to cadets

from Sandhurst, on their passing the required examinations, and paying the price of a commission. Exceptions to the latter condition were made in favour of cadets who passed high examinations at Sandhurst, and sometimes to young men whose fathers had distinguished themselves. Regimental commissions had fixed regulation prices, varying from £450, the price of an ensigncy in the infantry, to £7250, that of a lieutenant-colonelcy in the Life Guards; but in addition to this there was an over-regulation price according to the popularity of a regiment, contrary, indeed, to law, but sanctioned by long and universal usage, which sometimes exceeded the regulation price. On an officer retiring he received the regulation price of his commission from Government, and his place was filled in the regiment by the senior qualified officer of the next grade who was prepared to purchase it. When a vacancy occasioned several steps in the regiment, the price of the retiring officer's commission was made up by the various officers who were promoted, each subscribing the difference between the price of a commission in the rank they were promoted to, and that of the one they previously held. Officers who were too poor to purchase remained till they became senior of their rank, and held that position till a death vacancy or 'non-purchase step,' such as the appointment of the colonel to be a major-general, or the augmentation of a regiment, gave them promotion. Little can be urged in favour of the P. S. Its advocates were wont to compare the prices paid for commissions with the cost of a university education, and the fees required in entering the learned professions, and to say that it worked well, and that the officers of the army were drawn by it from the classes best fitted to be leaders of men. It stimulated, also, a rapid flow of promotion, and the poor officer benefited in the long run pecuniarily, as he was able, on his retirement after a number of years, to realise the commission of the higher rank he had been promoted to, although he had not purchased it. But there can be no doubt of the radical injustice of promoting officers according to the weight of their purses, and that, by the frequent sacrifice of the able man to the rich man, much injury was done to the efficiency of the service. The portions of the army which were not subject to the P. S. were the 19th, 20th, and 21st regiments of cavalry, the 101st to the 109th regiments of foot, and the artillery, engineers, and marines. The Army Regulation Act, 34 & 35 Vict. c. 86, provided for the compensation of officers who held saleable commissions at the time of the abolition of purchase. By the Regimental Exchanges Bill, 1875, an arrangement was made rendering legal the payment of money between officers who, on account of health or other reasons, might wish to make exchange of regiments or station among themselves, which is the only relic of the P. S. now in force. For the system of officering the army which now obtains, see PROMOTION.

Purified (from Fr. *pur*, 'for,' and *fil*, 'a thread'), or **Purified**, in heraldry, garnished or decorated with a rich bordure, as of fur. The word has a place in the older English literature, e.g.:—

'I saugh his sleeves *purified* atte honde.'—*Chaucer*.

'*Purified* with gold and pearl of rich assay.'—*Spenser*.

Purgation. See ORDEAL.

Purgatives are medicines which produce evacuation of the bowels. Various divisions of P. have been proposed by different authors. Dr. H. C. Wood proposes the following as the most convenient:—(1) *Laxatives*—Medicines which simply unload the bowels, and are not able to cause active purgation, even when given in very large doses, as tamarinds, manna, magnesia, and sulphur. (2) *Purges*—Medicines which purge actively, but are not capable of acting as poisons, even in very large amount, as castor-oil, hydrargyrum, rhubarb, aloes, senna, and saline P., as salts of magnesium, potassium, and sodium. (3) *Hydragogues*, which produce very large watery stools without much irritation. In overdoses, medicines of this class assume some of the characters of those of the next. (4) *Drastics*, which cause great irritation of the alimentary mucous membrane, and in overdoses are violent poisons, as jalap, colocynth, scammony, podophyllum, elaterium, gamboge, croton-oil, black hellebore, &c. See CATHARTICS.

Purgatory, according to the Roman Catholic doctrine, is a state of suffering into which all those pass who die in the peace of the Church without being perfect. The design of the suffer-

ing, which is popularly supposed to be produced by material fire, although it is not so stated authoritatively, is expiation and purification; the duration and intensity being proportioned to the guilt and impurity of the sufferers. The time during which any soul remains in P. may vary from a few hours to the whole period till the day of judgment. It may be shortened as well as the sufferings alleviated by the prayers of the living, especially by the sacrifice of the Mass. And it is thus in the power of the Church to remit the sufferings of P., partially or altogether.

This doctrine was developed from certain ideas and practices which prevailed in the early Church, and more than all from the universal practice of offering prayers for the dead. This was done for various reasons. 1. From a belief in the immortality of the soul—that the deceased were not extinguished, but were still alive. 2. It was believed that the true happiness or final misery of the departed did not begin till after the resurrection and the general judgment. Till that time they were secluded in some invisible place (Gr. *Hades*, Heb. *Sheol*, see HELL), with the exception of martyrs, who went at once to Paradise. Hence, in offering prayers for the dead, it was desired that they might be brought to 'the glory of the resurrection' and 'the perfect fruition of happiness in heaven.' 3. It was conceived that all men die with some taint of frailty and corruption, and in prayers for them it was desired that God would deal with them not in strict justice but according to his mercy. 4. Again, according to the Millenarian ideas, which were almost universally held in the Church during the first two centuries, it was believed that the righteous dead would rise to take part in the Millennium (q. v.), some sooner some later, according to their merits and preparedness for it. Hence prayers were offered for them that they might be privileged to take part in 'the first resurrection.' In short, as has been said, 'the belief in a lasting desire after a higher degree of perfection, which death itself cannot quench, degenerated into a belief in P.' When the belief in the Millennium began to fade, as it did after the 2d c., the belief in the necessity for an intermediate state in the region of the dead seems to have increased. There came in, too, from the East and from Greek philosophy, the ancient ideas about the purifying properties and functions of fire (cf. Zech. xiii. 9, 1 Cor. iii. 13, 1 Pet. i. 7, Rev. iii. 18). The first idea which prevailed in the Church, however, regarding a purifying fire (Lat. *ignis purgatorius*), was that it would have to be endured by all at the last day. According to Augustine (354-430) it was located in Hades, i.e., the intermediate place of the dead. The first to set forth the doctrine of P. as an article of faith was Gregory the Great (540-604), who was also the first to propound the idea of deliverance from it by intercessory prayer, masses, &c. Such ideas were confirmed by lapse of time, and as these masses and ecclesiastical indulgences were paid for, the doctrine led to flagrant abuses in the Church; so that it was one of the chief doctrines attacked at the Reformation, and rejected by Protestants. See Neander's *Geschichte der Christlichen Religion und Kirche* (Eng. trans. Lond. 1858), Hagenbach's *Lehrbuch der Dogmengeschichte* (Eng. trans. Edinb. 1847), Hodge's *Systematic Theology* (Edinb. 1873).

Purification has been regarded by most Eastern nations from ancient times as necessary for the removal of certain kinds of uncleanness, which, without such P., cut off the unclean person from public worship. Such was the case among the ancient Egyptians; among the Persians, some of whose purificatory rites are preserved by the Parsees (q. v.) to this day; and among both ancient and modern Hindus and Hebrews. In the Mosaic Law the different forms of uncleanness requiring P. were (1) that caused by contact with dead bodies, both of man and beast; (2) the uncleanness of leprosy; and (3) that produced by both diseased and normal functions of the human organs of generation (Lev. xi.-xv., Num. v. 1-4). The lower grades of these could be removed by simply washing with water, but the higher needed sacrificial expiation also (Lev. xv.). The uncleanness caused by contact with a corpse was specially intense, and therefore required an extraordinarily stringent P., by means of a wash specially prepared with sacrificial rites (Num. xix.). A still more stringent law applied to the priests. They had to undergo P. when first set apart for the priesthood (Lev. viii.), and again every time they approached the altar of God (Ex.

xxx.). See Kitto's *Cyclop. of Bib. Lit.* (3d ed. Edinb. 1876), Ewald's *Alterthümer des Volkes Israel* (Eng. trans. Lond. 1876), Kurtz's *Der Alttest. Opfercultus* (Eng. trans. Edinb. 1863).

Purification of the Virgin Mary is a Holy-day observed by some churches on the 2d of February in memory of the presentation of Christ in the Temple (Luke ii. 22-24, Lev. xii.). When first introduced (about the beginning of the 6th c.) it seems to have been in honour of Christ himself, having been called *Hypapante* (Gr., from *hypantaō*, 'I go to meet'), in reference to the meeting with Simeon (Luke ii. 25-35). Other names for it were the Feast of St. Simeon, the Presentation of the Lord, and Candlemas (q. v.). In the Greek Church it was always reckoned among the Festa Dominica.

Puritans were the popular party in England in the 16th and 17th centuries, corresponding to those who in other countries brought about the Reformation. In England, however, the authors of the Reformation were Henry VIII., Elizabeth, the Protector Somerset, and Archbishop Cranmer, and not the people. As first carried out by Henry, the Reformation was to consist simply of a transfer of the Papal supremacy to himself; all the Catholic rites and doctrines were to be retained. It was only by force of circumstances that the Government was driven at last to join the Protestants, and consequently the smallest possible concessions were made to their demands. The Reformation as completed under Elizabeth was essentially a compromise; and the Church of England 'continued to be, for more than a hundred and fifty years, the servile handmaid of monarchy, the steady enemy of public liberty.' The P. were the champions of religious liberty; and to them alone it was due that religion and liberty were not totally dissevered.

To Elizabeth the most important and valuable part of Protestantism was the Royal supremacy, and the basis of her policy towards the Church was the Act of Supremacy (1559), which placed all ecclesiastical jurisdiction in the hands of the State, and the Act of Uniformity (1559), which prescribed a course of doctrine from which no variation was legally permissible. In consequence of her rigorous enforcement of uniformity by means of an ecclesiastical commission, her reign is stained by cruel persecution. This persecution at last drove some of the P. from the Church (1567), and the first Presbyterian congregation was formed at Wandsworth, 1572. When the sect of the Brownists, who were afterwards known as the Independents, was formed (about the end of the century), there were three parties of P.—the moderate P. within the Church; the Presbyterian or Calvinistic party, who wished to have the Church modelled on that of Geneva; and the Separatists or Independents, who took up the position that a national Church at all is contrary to the Word of God. The Millenary petition, which was presented to King James on his accession (1603) by 800 Puritan clergymen, was not Presbyterian, and only asked for certain reforms in ecclesiastical matters. But James was as much opposed to any such changes as Elizabeth. Besides, he chose to confound the P. with the Presbyterians (as is yet done by High Church writers), by whom he had been withstood in Scotland. Hence, although he agreed to a conference between the P. and the Conservative party at Hampton Court, the former got no redress of their grievances. The High Church tendencies which prevailed under Charles I. (1625) drove a great number of moderate clergymen who had hitherto conformed to the law of the Church to side with the P. When the Church of England fell with King Charles (1649), the character of Puritanism necessarily changed, because the old grounds of contention had ceased to exist. From this time, accordingly, the P. are lost among the Presbyterians (q. v.) and the Independents (q. v.).

The peculiar tenets of the P. were briefly these: 1. That it did not belong to the State, but to the Church, to restore religion to its purity and dignity. 2. That the Holy Scriptures were the only source from which rules could be derived for regulating the Church, all the principles of Church government being therein laid down. 3. That the Church of Rome had become so corrupt as to have forfeited the rights of a true church. 4. That it was wrong to impose as necessary things those which Christ himself had left free, and that such rites as tend to superstition cannot be regarded as indifferent, but ought to be avoided as impious and profane. See *Works of the Reformers* (Parker Soc., Camb. 1841-54); Foxe's *Book of Martyrs* (1563); Strype's *Ecclesiastical Memorials* (2d ed. 1725-37; *Lives of Cranmer,*

Parker, &c.; Burnet's *History of the Reformation* (1679 seq.); Hallam's *Constitutional History of England* (1867); Neal's *History of the P.* (1732 seq.); S. R. Gardiner's *First Two Stuarts and the Puritan Revolution* (Lond. 1876); and Bayne's *Chief Actors in the Puritan Revolution* (Lond. 1878).

Purl, a drink prepared by heating ale or beer, adding to it a proportion of bitters, and strengthening the mixture with spirits. It is considered a tonic by those who indulge in hard drinking.

Purlin, in architecture, is a piece of timber placed on the main rafters of a roof, and supporting the common rafters.

Purmurende, a town of the Netherlands, province of N. Holland, between the two great polders of Purmer and Beemster, 10 miles N. of Amsterdam by the celebrated N. Holland Canal. Situated in a district noted even in Holland for the perfect system and productiveness of its dairy-farming, P. is a great market for cheese (1,500,000 lbs. yearly), butter, eggs, cattle, &c. Pop. (1873) 4545.

Purneah, the chief town of the district of the same name, in Bengal, British India, on the left bank of the Surah river, a tributary of the Ganges, 283 miles N.W. of Calcutta. Pop. (1872) 16,957. It is an unhealthy place, which has decreased in importance since it was the residence of a Mahomedan Nawab. The district of P., which stretches from the Ganges to the Nepal frontier, has an area of 4957 sq. miles. Pop. (1872) 1,714,595. The W. part has been devastated by changes in the course of the Kosi river, and there are wide tracts of uncultivated pasture land. The crops are rice, oil-seeds, tobacco, jute, and wheat, which are largely exported down the Ganges. Indigo has been extensively cultivated for the last 100 years under European management. There are manufactures of blankets, gunny, and paper; and a specialty of inlaid metal-ware, of zinc mixed with copper. In 1876-77 the registered exports were valued at £496,000, and the imports at £640,000, chiefly piece-goods. The principal marts are Dulaganje and Caragola.

Purple (Fr. *pourpre*, Lat. *purpura*, Gr. *porphyrios*), a secondary colour compounded of red and blue, in which the red predominates. In painting, the tint is produced by mixing red and blue pigments, but certain purples are used direct, the chief of which is *madder P.*, a lake in which madder is the colouring ingredient. The Tyrian P. of antiquity, prepared from the *murex*, was a colour of great renown. P. of Cassius is an exceedingly rich colour, prepared from the chlorides of gold and tin, and used for giving a rich ruby tone to glass as well as for porcelain painting. P. is the colour of imperial and royal distinction.

Purple Emperor (*Nymphalis* or *Apatura Iris*), a species of butterflies found in Britain and attaining a large size—some measuring from 2 to 3 inches in expanse of wings. The P. E. is frequently to be found hovering near the top of oak trees. It derives its name from the preponderance of purple in its colours.

Purple Wood or **Purple Heart** of Guiana is the heart-wood of two leguminous trees named *Copaifera pubifera* and *C. bracteata*, and is exported from that country to Europe in small pieces, principally for the manufacture of gun ramrods. It is of a fine grain, and a peculiar puce colour. Trinidad P. H. is *Peltogyne paniculata*.

Purpura, or the **Purples**, is a disease in which the blood or the capillary vessels throughout the system, or both, are altered. Small round spots of a dull red or deep purple colour, due to ecchymosis of the cutaneous capillaries beneath the cuticle, are visible on various parts of the surface. P. is frequently accompanied with hæmorrhage from mucous membranes, and extravasations of blood within the substance of the several viscera. The lungs, the brain, the liver, and the alimentary canal are most frequently affected. The spots of P. generally appear first on the legs, and afterwards on the thighs, arms, and trunk of the body. The colour of the spots is not altered by pressure, and they may be distinguished from flea-bites by the absence of a central puncture. The spots are first bright red, in a day or two they become purple, afterwards brown, and finally they assume a yellowish tint. Sometimes

all these varieties of colour may be seen on a patient at the same time. The disease is generally ushered in by languor, faintness, and gnawing pains at the pit of the stomach. The tongue is coated with a viscid fur, and the complexion is sallow, dingy, or bloated, with swelling underneath the eyelids. In some cases there is giddiness or lightness of the head, or palpitation and irregular action of the heart with a tendency to syncope. The causes of P. have not been well ascertained; but it most frequently appears under the long use of a poor diet, much sedentary occupation, mental distress and anxiety.

Treatment.—Free evacuation should be first effected, and continued until the febrile symptoms disappear. The diet should consist of boiled rice with whey, or the light subacid fruits, as grapes, oranges, strawberries, baked apples, and the like, animal food being avoided. Tamarind water, or water acidulated with sulphuric acid, may be freely used. When the spots have disappeared and hæmorrhage has ceased, light soups should be given and tonics administered. During the hæmorrhagic stage, oil of turpentine, administered in moderate and repeated doses, has been recommended. The tincture of larch bark in fifteen drop doses may be taken every hour, or eight or ten drops three times a day, afterwards increasing the dose according to circumstances.

Purpura, a genus of *Gastropodous* Molluscs belonging to the Whelk family *Buccinide*, and represented by the Common Purple Whelk (*P. lapillus*) of the British coasts. They are the animals which supplied the famous Tyrian purple dye. The Purple Whelk of the British coasts has a whitish shell banded with brown. In this genus the aperture of the shell is of moderate size and is notched in front, while the inner lip of the shell-opening is flat.

Purpure, in heraldry, the colour purple, represented by diagonal lines drawn from the sinister to the dexter side of the shield.

Purpurin, one of the chief colouring matters of Madder (q. v.). It crystallises in red needles from the solution in alcohol of the red precipitate which results from treating with sulphuric acid fermented madder previously boiled in a strong solution of alum.

Purre. See DUNLIN.

Purroah, or **Peruah** (properly *Panduah*), a ruined city in the district of Maldah, Bengal, British India, 24 miles N.E. from Gür, and 197 N. from Calcutta. It was the capital of an independent Mahomedan kingdom of Afghans in Bengal, in the 14th c., when the seat of government was temporarily transferred from the neighbouring metropolis of Gür. The ruins are extensive, and have never been thoroughly explored, being overgrown with jungle, the haunt of man-eating tigers. It is now only inhabited by two confraternities of fakirs, who are the attraction of annual pilgrimages. There are ruins of many mosques and palaces, constructed out of carved stone fragments of Hindu buildings evidently brought from Gür. Among these is the Adinah Masjid, the best example of Pathan architecture in India. See Fergusson's *History of Indian Architecture* (Lond. 1876).

Purse-Grab, or **Robber Crab** (*Birgus latro*), a species of *Decapodous* crustaceans belonging to the section *Anomura* (q. v.), or that represented by the hermit-crabs. In the genus *Birgus* the abdomen is of firm consistence, and has two rows of appendages. The thorax is heart-shaped. These crabs inhabit the Indian Ocean. They can endure removal from their native waters for an extended period, their gill-structures presenting some analogies to those of the land-crabs. A large specimen of the P.-C. may attain a length of 2 feet; the general colour is light brown. The P.-C. is noted for the dexterous manner in which it opens the shell of the cocoa-nut, smashing one end of the nut, and then extracting the substance by means of its claws.

Purser (Gr. *byrsa*, 'purse'), the title formerly of the officer in the Royal Navy who acted as treasurer and purveyor. Since 1844 the name has been changed to Paymaster (q. v.).

Purslane (*Portulaca*) is the type genus of *Portulacaceæ* (q. v.), and is familiar in the common P. (*P. oleracea*), a dwarf glabrous annual that has been cultivated from very early times,

but is not now so much esteemed as formerly. It is more or less naturalised in many warm parts of the world; and may be seen also in English culinary gardens. The properties are antiscorbutic, the young shoots and succulent leaves being used in salads, as a potherb, and for pickling. Sea P. is the common name for *Obione*, and water P. for *Peplis Fortula*.

Pursuer. See PLAINTIFF.

Pursuivant (Fr. 'follower'), in heraldry, an officer of the third or lowest degree in the College of Arms. It was originally an order of probation, from which were taken the heralds and kings-at-arms. In the Herald's College there are four pursuivants—*Rouge Croix* (of St. George), the most ancient; *Blue Mantle*, founded by Edward III. or Henry V.; *Rouge Dragon*, called after the 'red dragon,' dexter supporter to Henry VII.'s shield; and *Portcullis*, named after a badge of that king. The pursuivants of the Herald's College of Scotland are six, viz., *Dingwall*, *Bute*, *Carrick*, *Ormond*, *Kintyre*, and *Unicorn*.

Pus. See SUPPURATION.

Pu'sey, **Edward Bouverie, D.D.**, a nephew of the first Earl of Radnor, born in 1800, passed from Eton to Christ Church College, Oxford, where he took a first-class in classics (1822), obtained an Oriel fellowship, and was appointed Regius Professor of Hebrew, with a Christ Church canonry (1828). Along with Newman he was one of the chief promoters of the religious movement variously known as Anglo-Catholicism, Puseyism, and Tractarianism (q. v.), himself writing Nos. 18, 66, 67, and 69 of the *Tracts for the Times* (1833-41). A university sermon on the Eucharist (1843) led to P.'s suspension for three years, but at the end of that period he from the same pulpit quietly resumed the thread of his suspended argument, and has since laboured unhindered by pen and word of mouth for the restoration in the English Church of its 'primitive purity.' Among P.'s writings, besides translations from St. Anselm, Avrillon, Scupoli, &c., are *Doctrine of the Real Presence Vindicated* (1855); *History of the Councils of the Church* (1857); *Nine Sermons preached in the University of Oxford*, 1843-55 (1859); *The Minor Prophets, with a Commentary* (6 parts, 1862-77); *Church of England a Portion of Christ's one Holy Catholic Church: an Eirenicon* (1865); *Lenten Sermons* (1874); and *Advice on Hearing Confession* (1878).

Pushkin, Alexander Sergeivitch, a celebrated Russian poet, was born at Moscow, May 26, 1799, entered the 'Eton of Russia,' the imperial lyceum newly opened at Tsarsko Selo, in 1811, where he read and wrote much poetry; in 1817 became a clerk in the Foreign Office, and soon afterwards a member of the Arzamas Club, founded by Bloudoff in 1815. In 1820 the publication of his first poem of any length, *Ruslan and Ludmila*, provoked a literary controversy much like that which Wordsworth's *Ballads* raised in England, and called from Jukovsky the confession that he was 'outstripped.' Some bold utterances in unpublished poems led (1820) to his exile from St. Petersburg to Bessarabia, and afterwards to New Russia, during which he wrote *The Caucasian Prisoner* (1823), *The Fountain of Bakhtchiserai*, and *The Gipsies* (1824). In the autumn of 1824 he was suffered to return to his estate of Michaelovsky, in Pskov, where he wrote, besides a number of lyrics, the first half of *Eugène Onegin*, *Boris Godunoff*, and *Count Noulinc*. From 1826 P. was free to reside in any part of the empire. In that year he completed *Onegin* at Moscow, and produced *Pollava*, the greatest and most finished of his poems. For four years after his marriage (1831) with Nathalie Nikolaevna Gontcharoff, he lived in happiness. A number of anonymous letters in which his wife's name was coupled with that of one Dantès, an illegitimate son of Heekern, the Dutch Ambassador, being attributed by P. to Heekern and Dantès, led to a duel on the 27th January 1837, in which P. was mortally wounded. He died the next day. His wife and children were provided for by the Emperor Nicholas. The early years of P.'s literary life coincide with the energetic epoch in the history of modern Russia, when, compelled to exert her utmost strength against a powerful enemy, she first learned her own greatness. The full exponent of that period of transition, he scorned the 'affectations of classicism,' the 'weak offspring of a foreign school,' and for 'the cuckoo notes of elegists' employed a language of truthful simplicity.

There is a complete edition of his works in 6 vols. (1859-60). See Annenkoff, *Materials for the Biography of P.*, and *P. in the Reign of Alexander*; Gerdel, *Russian Poets*; and Galachoff, *History of Russian Literature*.

Pushtu (*Pakhtu*), the vernacular name of the language spoken in Afghanistan, and by the border tribes of the Dera Jat within the Punjab, British India. It was long supposed to be of Semitic origin, and thus to give a support to the cherished theory that the Afghans represent the lost tribes of Israel. But the labours of Dorn, Raverty, Trumpp, Bellew, &c., have now established that it belongs to the Indo-European family, being most closely allied to the Zend or Iranian branch, but having borrowed much from the Sanskrit. It forms a regular subject of examination for British officers at Lahore. The name has been plausibly connected with the Paktyes of Herodotus. See *Original Letters and Papers of the late Viscount Strangford upon Philological and Kindred Subjects* (Lond. 1878). For a list of P. proverbs, &c., see *Bannu, or Our Afghan Frontier*, by Mr. S. S. Thorburn, C.S. (Lond. 1876).

Pus'tule, Malignant. See MALIGNANT PUSTULE.

Pus'tular Diseases include those cutaneous diseases which are characterised by *pustules*, or circumscribed elevations of the cuticle containing pus. A certain degree of inflammation of the derma, greater than that which exists in the eczematous group of diseases, gives rise to the formation of pus, producing an elevation of the epidermis to a limited extent, termed a *pustule*. A true pustule contains pus from the first moment of its formation, and in this respect is essentially distinguished from a vesicle. Strictly speaking, there are but two P. D., viz., Impetigo and Ecthyma (q. v.), but the term is frequently loosely applied to various diseases which are at first papular or vesicular, and which afterwards become pustular.

Putchuck is the Bengal name for the root of *Aplotaxis Lappa*—the Costus of the ancients—an herb belonging to *Compositæ*, and found in the mountain-slopes of Cashmere. It is there collected in large quantity for export, the chief demand being for China, where it is used as an aphrodisiac, as well as for incense.

Puteaux, a town of France, department of Seine, on the left bank of the Seine, opposite the Bois de Boulogne. A favourite residence of Parisians, it has also thriving industries. Pop. (1872) 9491. Baron Rothschild's model farm is in the vicinity.

Putlogs, in architecture, short pieces of timber used to support the scaffold boards. They are placed at right angles to the wall, with one end resting on the ledges of the scaffold, the other in 'putlog-holes' (Lat. *columbaria*) left for them in the wall.

Put'ney, a town of England, in Surrey, 5½ miles W.S.W. of the Waterloo terminus, on the S. bank of the Thames, which is here spanned by a wooden bridge 805 feet long. It has two churches, St. Mary's and St. John's (1859), almshouses, a convent, Jesuits' College, &c., and numerous villas have risen up round the Heath. Thomas Cromwell and Gibbon were natives of P., which is now a great boating place, being the point from which the university boat-race starts. Pop. (1871) 9439.

Putrefaction (Lat. *putris*, 'rotten,' and *facio*, 'I make') is the term used to denote certain chemical changes which spontaneously take place in dead animal matter, during which offensive gases are evolved. Immediately life ceases a general metamorphosis and decomposition of the highly complex elements of organic bodies takes place, and they are successively reduced to definite and simple compounds. The presence of warmth, moisture, and air is requisite for complete decomposition, and the change can only be prevented by the absence of such conditions. In the dry, sandy deserts of Egypt, bodies of dead animals are reduced to a fine powder, and in the frozen snows of Siberia antediluvian elephants have been discovered in an edible condition. P. proceeds with great rapidity under water at 50° F., and in the air at 77° F., and much more rapidly in animal than in vegetable matters. The P. of dead bodies takes place with variable rapidity, but it does not commence until after the cessation of cadaveric rigidity, and generally about the third day, though in some cases it may have advanced rapidly within sixteen hours after death. The process of P. is

in principle identical with fermentation, but in detail it is slightly different. According to the investigations of Schröder, Pasteur, Tyndall, and Lister, the process of decomposition depends upon the spores of some organism gaining access to the substance, and P. can be arrested for an indefinite length of time by destroying such organisms in the substance, and preventing by a variety of means their ingress. The gases evolved during P. are injurious to health. There are many instances in which gravediggers have been attacked by serious symptoms after exhuming a body, and there can be no doubt that putrid emanations have occasionally caused death. Putrid substances, when confined in small places, such as dissecting-rooms, cesspools, &c., are extremely dangerous, and putrid vapours, though dissolved in water, are none the less hurtful. When putrid emanations are introduced into the circulatory system, fatal effects immediately follow. The blood becomes very thin, owing to diminution of fibrine and increase of free alkali. The products of P. produce disease, *sui generis*, but evidence is certainly contrary to the belief that putrefying organic matter is capable of originating epidemics.

Putrid Fever. See JAIL FEVER and TYPHUS FEVER.

Putteesala (*Pitidlia*), the capital of the native State of the same name, in N.W. India, in political connection with the Punjab Government, on a hill stream called the Kasilla, 23 miles S.W. of Umballa, and 1023 N.W. of Calcutta. It is a walled town, well built of brick, and clean. The Rajah's palace is in the citadel.—The State of P., which is much scattered, mostly lies between Ferozpur and Umballa, and on the hills around Simla; area, 5412 sq. miles; pop. about 1,586,000; revenue, £440,000; army, 8000 men, together with a contingent of 100 men furnished to the British for general service. No tribute is paid, but a *nuzzarana* or relief is due on the succession of collateral heirs. P. forms the most important of the Cis-Sutlej States founded by the Sikhs in Sihind during the last century. It has always been faithful to the British, from whom it has received large accretions of territory. In 1830, the sanitarium of Simla, with the adjoining hill territory, was ceded to the British in exchange for 3 villages in the plains. During the Mutiny of 1857 the Rajah kept open the communication on the Grand Trunk Road, and was rewarded with a grant of land yielding £20,000 per annum. The late Rajah, who died in the summer of 1876, at twenty-three years of age, shortly after having entertained the Prince of Wales, was an enlightened ruler. He had introduced the British system of civil and criminal procedure. He presented £7000 to the University College at Lahore; and in 1873, offered £10,000 on the occasion of the report of famine in Bengal. He was also well known as a connoisseur of precious stones. In 1875, Lord Northbrook laid the foundation-stone of a college at P. town. See *The Rajahs of the Punjab*, by Lepel Griffin, B.C.S. (Lahore, 1870).

Puttenham, George, born about 1530, educated at Oxford, distinguished himself at the court of Edward VI. by composing an eclogue entitled *Elphine*, travelled on the Continent, and on his return became a gentleman-pensioner of Queen Elizabeth. P. mentions a dozen of his own works; but only two of these have reached us. *Partheniades*, a set of twenty little adulatory pieces, was offered to the Queen as a birthday gift in 1579. The other work extant is its author's best—*The Art of English Poesie, in Three Books; the first of Poets and Poesie, the second of Proportion, the third of Ornament*. This book was published anonymously in 1589, but as early as 1605 was attributed to P. It is full of curious matter, and is of peculiar interest for its disquisition on shaped figures, as the lozenge, or rombus; the fuzie spindle, or romboides; the triangle, or triquet; the square, the pilaster, the taper, or piramis, rondel, egg, &c. P. says an Eastern traveller informed him that the fashion of writing verses in these forms was brought from the courts of China and Tartary. The *Partheniades* and *Art of Poesie* were reprinted, with notice of the author, by Hazlewood in 1811. The *Art* also forms one of Arbei's excellent reprints (1869).

Putty, used by glaziers, is a plastic mixture of fine dry whiting and linseed oil. For special purposes, as where the lap or hold is very narrow, a small quantity of white-lead is added. The ingredients are well kneaded, and after lying for some hours the mass is worked up in small pieces till perfectly smooth. Ochre, lampblack, or other pigment, is employed to colour it. P. may be softened by spreading over its surface a thin compo-

sition of pearl-ash and slaked lime. Plasterer's P. is thoroughly mixed the white lime formed into a paste with water.

Putty Powder is an oxide of tin, and is much used in polishing hard substances, particularly glass for optical purposes. It is best prepared by dissolving metallic tin in diluted nitro-hydrochloric acid, and precipitating the oxide with diluted ammonia. The precipitate is then thoroughly dried, exposed to a white heat in a crucible, and ground for use. Commercial P. P. is usually a mixture of oxidised tin and lead in equal parts.

Pay (Catalonian *puig*, probably from the Celtic *puech*), a name given in Auvergne and the Cevennes to the conical volcanic mountains so common in these districts.

Puy, Le, or Le-Puy-en-Velay, the chief town of the department of Haute-Loire in France, 70 miles S.W. of Lyons, at the confluence of the Borne and Dolaison with the Loire, is a very ancient city, and one of the most picturesque in France. It is the seat of a bishop, and its cathedral, a building of the 10th or 11th c., contains a famous miracle-working image of the Virgin. The present image is modern, the ancient one, said to have been an Isis figure brought from Egypt in the 8th c., having been burned at the Revolution. Near the town is the *Rocher de St. Michel*, a natural basalt obelisk 265 feet in height, surmounted by a chapel of the 10th c. On the basaltic mass of the *Rocher de Cornuille* stands a colossal statue of *Nôtre Dame de France*, cast from cannon taken at Sebastopol. The town is the centre of a great lace manufacture, employing 70,000 people in the surrounding districts, and producing over 10,000,000 francs' worth of lace in the year. Pop. (1872) 19,233.

Puy de Dôme, the most central department in France, bounded on the N. by Allier, on the W. by Creuze and Corrèze, on the S. by Cantal and Haute Loire, and on the E. by Loire. Area 3108 sq. miles; pop. (1876) 570,207. The Allier, a tributary of the Loire with its own tributary the Doré, flows through it northward. In the W. is the great volcanic chain of the Auvergne mountains, with the peak of P.-de-D. 4790 feet high, and the even higher peaks of the Mont-Dore groups. There are many warm springs in the mountains, which are rich in iron, coal, lead, antimony, arsenic, and good building-stones. Only about a fourth of P.-de-D. is cultivated land, rye being the principal product. Cattle and sheep breeding is much practised, and the principal industries are mining and the manufacture of paper and oil. The chief town is Clermont-Ferrand.

Puzzuola'na. See POZZUOLANA.

Pyæ'mia (Gr. *pyon*, 'pus,' and *hæma*, 'blood') is usually defined as an affection of the mass of the blood, characterised by a peculiar form of fever, and resulting in the formation of abscesses in various parts of the body. The cause of P. is probably due to the absorption into the blood of putrefying matter, and it is possible that some molecular change in the blood itself may cause spontaneous P. There are two forms or modifications of P. described—(1) the systemic affection, termed *septicæmia*; and (2) the true P., characterised by local changes or 'secondary deposits.' Much diversity of opinion has existed regarding the essence of P., but it is now generally admitted that it consists in the imbibition, by the blood, of matters in a state of putrefaction, which act as a ferment on the blood, and cause it to stagnate in the capillaries, resulting in the formation of secondary deposits.

P. is distinguished from traumatic fever in that the temperature maintains itself above the normal, and is exacerbated from time to time when the rigors take place, falling again as the sweating goes on. In more advanced stages, the disease may be recognised by the occurrence of visible deposits or internal inflammation. In P., the prognosis is, as a general rule, bad; but cases of recovery do take place, more especially in spontaneous P. The treatment of P. resolves itself into prophylaxis. All that can be done is to support the patient's strength, and treat the symptoms as they occur.

Pycnogonum, a genus of lower *Arachnidans*, belonging to the order *Podosomata*. *P. littorale* is a familiar species found amongst seaweed. The legs number four pairs, and the abdomen is narrow and linear in form. The legs contain prolonga-

tions of the viscera, and the mouth is formed on the suctorial type. No distinct breathing organs are developed, but the heart is present. The legs are provided with hooks adapted for enabling these animals to adhere to the seaweed amidst which they live.

Pygmies (Gr. *pygmæ*, a measure of length, $\frac{1}{3}$ inches, being the distance from the elbow to the knuckles), a diminutive race, the Lilliputians of the ancients, placed by Homer on the shores of Oceanus, by Ctesias and Pliny in India, and by Aristotle in Ethiopia. Their vain attack on Hercules, and ceaseless warfare with the cranes, formed the theme of countless stories. See GIANTS AND DWARFS.

Pym, John, born at Brymore, Somersetshire, in 1584, of a good family dating from the reign of Edward I., was a gentleman-commoner at Broadgate Hall, now Pembroke College, Oxford, (1599-1602), and there by his fine accomplishments earned from the poet Fitz-Geoffry the title of '*Phæbi delicia*.' He quitted Oxford without a degree, and entering one of the inns of court, soon attracted the notice of the Earl of Bedford, to whom he probably owed his post in the Exchequer. In the 'Addled Parliament' (1614) he sat for Calne along with Eliot and Wentworth, like whom he joined the Country party; and again, after six short years of married life, in that of 1621, when he seconded Coke's motion to remonstrate with his majesty on the prevailing discontents. With eleven other members, he also carried to Newmarket the Commons' demands for a war with Spain and a Protestant match. 'Bring stools for the Ambassadors,' cried James ironically, as the deputies entered his presence; and the session of 1621 closed with P.'s imprisonment. He was foremost, however, in promoting the impeachment of Buckingham (1626), and in the Parliament of 1628 stood second only to Eliot, whom in the debate on the Petition of Right he supported with the eloquence of a Bacon and the irony of a Mirabeau, but whom he opposed in the matter of Rolle, rightly preferring the kingdom's liberties to a member's privilege. In the Short Parliament (1640), 'when men,' says Clarendon, 'gazed on each other, looking who should begin (much the greater part having never sat before), P. brake the ice' by a two hours' exhortation 'to see how much work they had to do to satisfy their country.' And lastly, in that Long Parliament, on whose eve he had ridden through England's length, rousing the voters to their duty, he moved the impeachment of Strafford, his old ally of twelve years back, whom on their rupture P. had promised never to leave while his head was on his shoulders. His promise kept, and supplemented by the fall of Laud, he set himself to 'sweep the house from floor to roof,' by reforms which, ending in the Grand Remonstrance, led to the attempted arrest of the five members, and thence to the outbreak of civil war. Placed at the head of the Committee of Safety, P. turned his knowledge of finance to good account, held bravely out when Essex seemed faltering and Hampden had fallen on Chalgrove field, was arranging terms with Scotland, and had just accepted the lieutenancy of ordnance, when on December 8, 1643, he died at Derby House. 'King Pym' was buried royally in Westminster Abbey, whence at the Restoration his body was cast out into a pit in St. Margaret's churchyard, with Blake and Dorislaus and Cromwell's mother. Clarendon speaks of him as 'the most popular man, and the most able to do hurt, that have lived at any time;' and Mr. Gardiner says: 'It would be hard to find in the course of English history another man so fitted to his special task. A Conservative by nature, and instinctively opposed to the reception of new and unaccustomed ideas, he was the very man to head a revolutionary movement of which the object was to preserve as much as possible of the existing system in Church and State. To that task he brought untiring energy, great capacity for business, and knowledge of finance, combined with a delicate tact which enabled him to guide a large and fluctuating body of men.' See J. Forster's *Eminent British Statesmen* (vol. iii. Lond. 1837), Goldwin Smith's *Three English Statesmen* (Lond. 1867), and S. R. Gardiner's *Puritan Revolution* (Lond. 1876).

Pyne, Madame Louisa Bodda, an English soprano, was born in 1832, and made her first appearance in the opera in 1849. She was joint-lessee along with Mr. Harrison of Covent Garden from 1858 till 1862, and also the prima donna of the English Opera Company there. Wallace's *Lurline* and Benedict's *Lily*

of Killarney were produced under her auspices. She has since sung at concerts, and made operatic tours in the provinces. She is married to Mr. Frank Bodda.

Pyracon'tha. See CRATÆGUS.

Pyramid, in geometry, is a solid figure formed by drawing right lines from every point in the periphery of a plane polygon to any point outside its plane. Every side is therefore a triangle, having its vertex at the apex of the P.; and the number of sides will equal the number of sides of the polygon which forms the base. According to the form of the base different forms of P. correspond, which are distinguished by name. Thus we have the triangular P., the square P., the hexagonal P., etc. The triangular P. is ordinarily called the tetrahedron. The cone is the limiting form of P., as the sides are increased indefinitely in number, and diminished indefinitely in magnitude. The volume of a P. is one-third the volume of the prism which stands upon the same base and is of the same altitude; hence pyramids upon equal bases and of the same altitude are equal. The word is undoubtedly of Egyptian origin, but its derivation is very obscure. De Sacy regards it as denoting an edifice set apart for some religious purpose; and it is agreed almost universally that the remarkable structures known as the Pyramids of Egypt were originally sacred edifices. By extension the word has come to mean any object bearing a resemblance to these architectural works of antiquity.

The pyramids of Egypt number in all about seventy; but of these only three deserve particular notice on account of their magnitude. These, with six smaller ones, constitute the group known as the pyramids of Gizeh, 10 miles W. of Cairo. The Great P. was the sepulchre of the Cheops of Herodotus, and is also called the Cheops or Khu-fu P. It is 449 feet high, and its square base, each side of which is 746 feet long, rests upon Nummulitic limestone, about 100 feet above the level of the Nile. Its original height was 480 feet, but it has been much spoiled by the removal of the external stones for building purposes. The sides, which look directly to the cardinal points, are inclined to the horizontal at an angle of 52°, and the summit, from which a splendid view is obtained, is now a flat, square space, with a side of nearly 35 feet. There are three chambers, reached by galleries which branch from a main gallery opening at the middle of the N. side. The largest and highest chamber is 34 feet long, 17 broad, and 19 high. It is 300 feet below the apex, and contains a sarcophagus of red granite. The lowest chamber is below the base of the P., and the main duct leading to it is inclined to the horizontal at an angle of 26° 18'. This inclination has given rise to the supposition that it served to mark the meridian passage of some bright polar star. About 4000 years ago, a person stationed at the bottom of the gallery would observe the meridian passage of γ Draconis. This fixes the date of the Great P. at 2123 B.C. According to Sir G. C. Lewis, however, in his treatise on the *Astronomy of the Ancients*, there is no sufficient historical reason for placing any of the pyramids at an earlier date than the building of Solomon's Temple, 1012 B.C. The second P., that of Chephren or Schafra, is nearly as large as the Great P., and stands on higher ground. It has two openings, one on the N. and one on the S. side, and bears evidences of having been increased in size at different times after its first erection. The third P., that of Mykerinos or Menkera, is less than half as high as the first two, but in beauty of execution it surpasses those. The royal mummy found in it is now in the British Museum. Near this P. are three smaller ones, which are supposed to be the tombs of relatives of the king. At Abu-Sir, Sakkarah, Dashur, El-Metanich, &c., are other interesting P.-groups. They are much smaller structures than those of Gizeh, but contain many valuable inscriptions in hieroglyphics. Pyramids are not confined to the Old World, but are found in Mexico. That of Cholula has a larger base than the Great P. of Cheops, but it is truncated, and not nearly so high. Its four sides face the cardinal points, and on its summit stood the temple of Quetzalcoatl, the god of the air. At Teotihuacan are two large pyramids dedicated to the sun and moon, and a number of small ones supposed to have been dedicated to the stars. The labour necessary to erect these immense structures must have been prodigious, seeing that machinery was unknown. The huge stones were probably raised to the proper height by being drawn up long inclined planes upon rollers. See Dunsen's *Egypt's Place in Universal History*; Gliddon's

Ancient Egypt, Piazza Smyth's *Our Inheritance in the Great P.*, Bonwick's *P. Facts and Fancies*, and Prescott's *Conquest of Mexico*.

Pyramus and Thisbe were two lovers in Babylon, whose story has been told in Ovid's *Metamorphoses*. They found means of escaping the jealousy of parents by conversing through a hole in the wall which separated their houses, and agreed to meet at the tomb of Ninus. Thisbe arrived there first, and, terrified by the sight of a lioness rending an ox in pieces, fled to a cave, casting aside her mantle. The lioness soiled the mantle with blood, and Pyramus, approaching, imagined that Thisbe had been devoured, upon which he fell on his sword. Thisbe, emerging from the cave, found her dead lover, and killed herself with the same sword. This scene was enacted beneath a mulberry tree, the fruit of which, before white, has ever since been of the colour of blood.

Pyrenees (Span. *Pirineos*, from Basque, *pyrr*, 'fire'), the mountain-system which separates France and Spain, extending from Cape Creuz on the Mediterranean to the S.E. corner of the Bay of Biscay, with a length of 267 miles and a breadth of 13 to 69 miles, and covering an estimated area of 12,756 sq. miles. The system is made up of two great parts, both of which have the same general direction, but do not form a continuous line. The P. are divided into three regions, East, West, and Middle P.—(1) The East P., 130 miles in length, begin near Cape Creuz and continue in an unbroken wall of granite to the source of the Tech, rising in Monte Castabon to 8085 feet, and N. of the main ridge, in the Aspres ridge in Monte Canigou to 9140 feet. Further W. are Pic de Carlitte (9583 feet), Pic de Pedroux (9290 feet), Pic de Serrère (9551 feet), Pic Siguer (9528 feet), Pic de Montcalm (10,105 feet), and Pic de Mont Ronch (9402 feet). Between two of the spurs is the valley of Andorra (q. v.). (2) The Middle P., 69 miles in length, extend in two parallel chains, of which the northern rises in Pic du Midi de Bigorre to 9440 feet, and in Pic d'Arbizon to 9290 feet. In the southern chain the chief peaks are Puig d'Anehou (Maladetta, 10,848 feet); Pico Batoua (9961 feet); Vignemale or Villamana (10,798 feet); the three-crested Monte Perdido (11,001 feet), which, with Marboré (10,673 feet) and Cylindro (10,917 feet), forms the three *sorores* or *sorellas*, the central mass proper of the P., and the Pico Taillou (10,323 feet). W. of Vignemale, the general height sinks to 5250 feet, but rises in Pic du Midi d'Ossau to 9467 feet, and in Pessa Colorado to 9477 feet. (3) The West P. extends 64 miles in a single chain descending to the W. from Puerto de Gabadaille to St. Jean de Luz, with a height varying from 5250 to 2130 feet. The highest point is Pic d'Anie (8218 feet), and the range terminates in the splendid granite cone of Mont Aitchuria (2485 feet). The chief valleys of the P. are transverse. The head is termed a *col* or *port*. The principal are the valley of Aran, from which the Garonne flows to the N. through a cleft; the valley of the Fluvia, 27 miles long, containing near Olot and Castelfolit lava streams and 14 volcanic cones with craters; the valleys of the Bidassoa and Baztan ('garden'). There are many narrow clefts without vale-bottoms, which communicate through rocky passages called *labats*. They usually begin on the height in circular basins, sometimes of considerable size and depth, which form lakes often at such a height as to be frozen eight to nine months of the year. Among these valleys the principal are the Orla de Gavarnie at the foot of Monte Perdido, from which flows the Gave de Pau, the Val de Ter, Val de Llohergat, Val de Segre, 92 miles long, Val de Andorra, and Val de Tena. The passes across the P. are nearly 100 in number, but of these only 7 are practicable for waggons and 28 for mules. The chief are those of Col de Pertus, over which runs the road from Perpignan to Barcelona, and by which Hannibal and Julius Caesar crossed; Port de Canfranc; and Port de Salo, over which runs the road from Toulouse to Lerida. Some of the highest are those of Viella (8225 feet), through the Maladetta, the Port d'Oo (9856 feet), and the Brèche-de-Roland (9200 feet). Metamorphic rocks compose the great mass of the P., with red sandstone and Alpine limestone, and primitive rocks, chiefly granite and gneiss. Towards the middle of the range micaceous schist is found. Iron-ore is abundant, and copper, lead, and silver have been found. Excellent marble is obtained. The region of perpetual snow, which begins on the N. side at 8954 feet, and on the S. at 9998, contains no great ice-fields and few glaciers. The limit of trees in the Port de Canfranc is 4593 feet,

near Panticosa 5906 feet, and in the E. P. 7349 feet. To the S. it becomes higher. On the northern declivities middle European vegetation is found. On the S. side, considerably above the limit of trees, are found the box, and higher the *Pinus pyrenaica* and *abies*; in the W. the *Pinus sylvestris*, *Quercus ilex*, and *Troja*. But in general the vegetation is not rich.

Pyrenées-Basses, a department occupying the S.W. corner of France, and of which the S. consists of the western Pyrenees and their spurs. In the N. are fertile undulating plains. The department is watered by the Adour, which in the latter part of its course forms the boundary between P.-B. and Landes, and to which flow from the Pyrenees the Nive, Bidouze, Gave de Pau, and the Gave d'Oloron, formed by the Gave d'Ossau and Gave d'Aspe. The Pyrenees have here no longer snow-clad peaks, but rather wooded summits, separated by richly-cultivated valleys. Along the Gave de Pau is fine arable land. The chief productions are wines, flax, hemp, maize, and rye. In the highlands, the breeding of cattle and horses is the principal employment. The chief industries are weaving, tanning, and the manufacture of paper, glass, and ironwares, while there is considerable export of wood, turpentine, tar, iron, wine, brandy, wool, hams, pigs, and horses, chiefly through Bayonne and St. Jean de Luz. The chief minerals found are coal, peat, lignite, anthracite, rock-salt, marble, sandstone, and slate. There are many mineral wells, of which the most frequented are those of Cambo, Salies, and Biarritz. Area, 2943 sq. miles. Pop. (1876) 431,525.

Pyrenées-Hautes, a department of France E. of the Pyrenées-Basses, containing within it the loftiest part of the Pyrenees range. In the N. the surface is level and fertile, but in the S. it consists of steep mountains, with jagged, glacier-covered summits, separated by valleys covered with alternate meadow and wood. Many *gaves*, or mountain streams, with cascades, flow into the Adour and Garonne. The chief of these are the Gave de Pau, in its upper course flowing into the Adour, and the Neste, Gers, and Baise, which join the Garonne. The climate is mild, though sudden and destructive storms are frequent in the highlands. The chief crops are the ordinary cereals and leguminous plants, besides flax and fruits—including mulberries, figs, and grapes. Cattle, horses, pigs, sheep, and poultry, especially geese, are reared. There are some manufactures of linen, cotton, and woollen stuffs, paper, cutlery, nails, hides; and the chief minerals found are iron, copper, zinc, lead, manganese, nickel, cobalt, marble, slate, and granite. The principal mineral wells are those of Barèges, Cauterets, Saint-Sauveur, and the sulphur wells of Viscos. Area, 1749 sq. miles. Pop. (1876) 238,037.

Pyrenées Orientales, a frontier department of France, having E. the Mediterranean and S. the Pyrenees. A marshy and unhealthy plain extends along the coast, which has a length of 45 miles, and the interior is traversed by two ranges of mountains, one running from W. to E., dividing the Tet from the Gly, and the other starting from Mount Canigou and running S. and E., separating the Tech and Tet basins. The Segre, a tributary of the Ebro, drains the S.W. The climate is excellent and the soil generally rich and fertile. Mulberries, pomegranates, olives, and oranges, growing on the hill-slopes, indicate the Mediterranean vegetation. Much Roussillon wine is produced, two-fifths of which is exported, the most esteemed kinds being those of Rivesaltes, Collioure, Salces, and Saint-Nazaire. Numbers of horses, mules, and cattle are exported, and considerable quantities of fish, with which the coast-sea abounds. There is little mineral wealth, but mineral springs are frequent, the chief being at Amélie-les-Bains, Vernet, Graus, d'Oilet, Vinca, and Moligt. Area, 1592 sq. miles. Pop. (1876) 197,940.

Pyrites, in mineralogy the name given to a group of metallic sulphides or arsenides, of which iron P. is the most important. It is a brittle, bronze-coloured ore, crystallising in cubes or related forms, but occurring also massive. It is of great industrial importance as the source of sulphate of iron and the sulphuric acid of commerce. See IRON. The name P. is derived from the Gr. *pur*, 'fire,' since the ordinary iron P. strikes fire with steel. *White iron P.* and *magnetic P.* are recognised varieties. *Arsenical iron P.* contains the arsenide as well as the sulphide.

It crystallises in rhombic prisms, is silver-white in colour, and also brittle. It is known as mispickel, and is ordinarily found associated with ores of silver, lead, iron, or copper. *Auriferous P.* contains a small quantity of gold. *Copper P.* is a brassy-yellow, iridescent mineral, crystallising in tetrahedra and octahedra. It yields easily to the point of a knife, and does not strike fire like iron P., with which it is usually associated. In composition it is a double sulphide of copper and iron. It is extensively worked for copper in Sweden, Cornwall, the Hartz, and other localities where it occurs, and is besides the chief source of sulphate of copper, the blue vitriol of commerce. See COPPER. *Variegated copper P.* is a variety which tarnishes rapidly on exposure. It contains a much greater percentage of copper than the ordinary kind. *Nickel, or capillary P.*, is brassy-yellow in colour, occurring usually in delicate capillary forms, but sometimes in rhombohedra. It is found in Bohemia, Saxony, and Cornwall. *Tin P.* is steel-grey or yellowish, occurring massive or in cubes. It is a triple sulphide of tin, copper, and iron, which are present in the proportions 27, 30, 13. It is very rare, and has been found in Cornwall, where from its frequently bronze appearance it is known as *bell-metal ore*.

Pyrütz, an old walled town of Pomerania, kingdom of Prussia, 25 miles S. by E. of Stettin. It was an important stronghold of the Wends, of whom there are many interesting traces, including five high wall-towers. Here Otto of Bamberg baptized the first Pomeranian converts in 1124. P. has a trade in agricultural produce and some woollen and leather industries. Pop. (1875) 7443.

Pyrola and **Pyrolacææ**. See WINTER GREEN.

Pyroligneous Acid is the crude acetic acid obtained by the destructive distillation of wood. The first acid liquor consists chiefly of P. A., wood naphtha, and acetone. The two last boil at 65° C. and 56° C. respectively, and distil over first, while the first boils at 117°. The various tarry impurities which are still present in the P. A. must be got rid of in order to prepare pure acetic acid. See ACETIC ACID.

Pyroligneous Spirit. See PYROXYLIC SPIRIT.

Pyrolusite is an iron-black mineral, crystallising in small rectangular prisms, and sometimes occurring fibrous, radiated, massive, or reniform. It is the binoxide of manganese. See MANGANESE. It is extensively worked in Thuringia, Moravia, and Prussia, and is used for discharging the brown and green tints of glass. Usually associated with it is *Psilomelane*, which differs from P. in containing some barium or potassium, and is distinguished by its superior hardness. By some it is regarded as merely an impure variety of P.

Pyromancy, among the Greeks a species of divination by the flames of a sacrifice, good-luck being betokened by the quick consuming of a victim, and evil by the opposite.

Pyromania is an involuntary, motiveless impulse to destroy by means of fire. It is doubtful whether there is any such distinct form of mental disease; but there is undoubtedly a powerful disposition in many lunatics to destroy articles by fire, and also to commit suicide by such means.

Pyrometer is the name applied to any instrument which is capable of measuring temperatures higher than those indicated by the ordinary mercurial thermometer. In Muschenbrock's original apparatus (1730), the change of temperature was shown by the expansion of a metal rod. This, and the various improvements effected by Desaguliers, Ellicott, Graham, Smeaton, and others, hardly deserved the name of P., for they were unable to measure high temperatures, and gave no accurate method of comparing the results for low temperatures with the standard mercurial thermometer. Wedgwood (1782) was the first to effect these ends with any degree of success. He measured the increase of temperature by the permanent contraction produced in a cylindrical piece of fine porcelain clay. His results were, however, uncertain and erroneous, and consequently his apparatus was soon abandoned. In 1804, a greatly improved form was devised by Guyton de Morveau. He measured the increase in temperature by the expansion of a bar of platinum, which rested in a groove cut in a plate of highly baked porcelain, the expansion being indicated by a lever, the short end

of which rested against the free extremity of the metal rod. Daniell's P., a still more trustworthy instrument, was constructed upon the same principle, with a mixture of black lead and clay instead of porcelain. The air thermometer (See THERMOMETER) was first employed by Prinsep in 1827; and Pouillet constructed one nine years later, the results of which he checked by other two ingenious forms of P. The one was by the production of the thermoelectric current at a junction of iron and platinum. This method, however, can never be applied with accuracy, since a difference in the constitution of a metal so slight as to be quite inappreciable to the most refined chemical tests is sufficient to make the metal a totally different substance thermoelectrically. The third method employed by Pouillet was by observing the rise of temperature of a given mass of water when a platinum ball at the required temperature was immersed in it. Knowing the specific heat of platinum and its mass, and also the resulting temperature of the water, the original temperature of the platinum can be easily calculated. Regnault, Deville, and Troost have made important researches in the expansion of bodies by heat, the property upon which the principle of all pyrometers depends. The platinum-palladium thermoelectric couple used by Becquerel (1863) is open to the objections indicated above. Siemens has suggested and utilised a method for determining the temperature by observing the change in electric resistance of a platinum wire. The empirical formula which he had deduced from experiment is

$$R = a\sqrt{t} \times bt + c$$

where R is the resistance, t the absolute temperature, and a , b , and c constants determined by experiment.

Pyrope, or **Bohemian Garnet**, occurs usually in rounded grains, and resembles in appearance a rich garnet. It is composed of silicates of aluminum, chromium, magnesium, iron, calcium, and possibly yttrium. It is found in Bohemia, in trap-tufa, and also at Elie, Fife; hence the popular Scotch name *Ehe Rubies*.

Pyrophorus (Gr. 'fire-bearing') is any substance which takes fire spontaneously in the air. The metals iron, nickel, and cobalt obtained as a fine powder by the decomposition of the peroxyl by means of hydrogen, behave in this way, as also the finely divided lead prepared by heating the tartarate till the organic portion is charred. In these cases, on account of the great surface exposed, the oxidation is so rapid that the temperature is raised sufficiently to cause the substance to glow.

Pyrosis or **Waterbrash** is a form of dyspepsia or indigestion, connected with organic disease of the stomach, or with the taking of some particular kind of food, as oatmeal, and is attended with the eructation of thin, tasteless, sometimes sour watery fluid. P. generally occurs in paroxysms in the morning or forenoon, when the stomach is empty, the first symptoms being pain, often severe, at the pit of the stomach, or a burning sensation, followed by a discharge of fluid. P. most commonly recurs, and is usually accompanied with other symptoms of dyspepsia. A form of P. depends on the presence in the stomach of fungi, called *Sarcina ventriculi*, discovered by John Goodsir in 1842. They are small flat bodies having a rectangular outline and a somewhat oblong shape, resembling little packets tied lengthwise and across with a string. P. may be treated as a symptom by the compound kino powder, combined with a purgative, as Friedrichshall or Pullna water; and when depending on the presence of fungi, sulphite of soda in 20 to 60 grain doses may be given. Sulphurous acid being set free in the stomach destroys the sarcinae.

Pyrosoma (Gr. 'fire-body'), a genus of *Tunicate* Mollusca, or Sea-squirts, of compound nature. They consist of an aggregation of Tunicate bodies, which are attached on each side of a central hollow stem or tubular structure. These animals swim freely on the surface of the ocean by means of the inhalation and expulsion of water from the tubular body. At night they shine with a brilliant phosphorescent light, whence their scientific name. *P. Atlantium* is the familiar species. It attains a length of from 4 to 7 or 8 inches.

Pyrotechny (Gr. *pyr*, 'fire,' and *technē*, an 'art'), the art of constructing fireworks. P. had its origin in the East, and many centuries before it was introduced into Europe, firework displays

were well known in China, and to this day the Chinese and Japanese excel in the production of fireworks of great beauty, brilliancy, and charming novelty. In Europe, P. was first practised at Florence about the middle of the 14th c., and thence a knowledge of it was carried to France, and subsequently to England and Germany. Large pyrotechnic establishments are now to be found in most of the European capitals. England has had several important pyrotechnic displays on occasions of rejoicing, notably those celebrating the peace of Ryswick in 1697, the peace of Aix-la-Chapelle in 1748, the general peace of 1814, and the termination of the war with Russia in 1856. The principal ingredients used in P. are nitre, charcoal, and sulphur, and these materials pulverised are mixed in variable proportions, according as the combustion of the firework is intended to be quick or slow, with other substances which impart colour to the flame. Gunpowder, in the form of meal or fine powder, also enters into the composition of several kinds of fireworks. There are very many substances employed as colouring agents, but those chiefly resorted to are nitrate of strontium, which yields a red tint; nitrate of barium, green; powdered malachite, violet; nitrate of sodium, yellow; sulphate of copper, blue; sulphide of antimony, white; filings of steel, iron, copper, and zinc also yield various colours, and are added where sparkling effects are desired. Fireworks may be divided into four classes—(1) *Single*, comprising the most simple kinds, as squibs, crackers, serpents, wheels, stars, &c.; (2) *Terrestrial*, embracing those works of complex construction that are set upon the ground, as suns, mosaics, waterfalls, *pyre pyrique*, Chinese fountains, fire-globes, and wheels of great variety and elaboration; (3) *Atmospheric*, or those which rise into the air, of which the rocket is the type; and (4) *Aquatic*, those which are fired on the surface of water or below it, and which consist of fire-balls, fire-globes, floating-suns, water-mines, water-rockets, fire-fountains, &c. With regard to the preparation of pyrotechnic mixtures, and the mechanical details for forming the numerous devices with them, recourse should be had to the many cheap manuals that are published on the subject.

Pyroxyllic Spirit, or **Wood Naphtha**, an important product of the distillation of wood. It is one of the more volatile liquid products, distilling over at 55° C., mixed with a considerable quantity of acetone and certain oily substances. It is chiefly composed, however, of methylic alcohol (CH₃O). To obtain this substance pure, chloride of calcium is dissolved to saturation in the crude wood spirit, when a crystallisable compound having the composition CaCl₂.4CH₃O is formed. Heated in a retort to a temperature of 100° C., the acetone and acetate of methyl present pass over; and the residue, when mixed with an equal mass of water and again distilled, yields methylic alcohol, the chloride of calcium remaining behind.

Pyroxylene, an explosive compound formed by the action of nitric acid upon wood, cotton, paper, and other forms of woody fibre. It is the active constituent of Gun Cotton (q. v.).

Pyrrhic Dance, according to Plato the most famous of all the Greek war-dances, was of Cretan or Spartan (i.e., Doric) origin; the accounts that it was invented by one Pyrrhicos, or by Neoptolemus, or Pyrrhus, son of Achilles, being quite fabulous. It was very quick and light (of the P. foot, ~ ~, and the Proceleusmatic, ~ ~ ~ ~), and was danced to the flute. Plato describes it as a preparation for war, imitating by its quick motions of the body the way to avoid missiles and blows, as well as the method of attack. But in non-Doric states it was purely mimetic, danced by the Athenian youths at the Panathenaic festivals, and often performed by women to entertain company. It was introduced into the Roman public games by Julius Cæsar, and was very popular with the Romans. Nero and Caligula both exhibited it. The armed dances of the mountaineers of Thessaly and Macedonia at the present day are thought to resemble the P. D.

Pyrrhōn, a famous Greek philosopher, was born at Elis in the first half of the 4th c. B.C. In his youth a painter, he was first attracted to philosophy by the works of Democritus, and along with Anaxarchus, his teacher, accompanying Alexander the Great on his Eastern expedition, he became acquainted with the Magians and Gymnosophists. From them, probably, he derived his aspirations after entire independence of everything external, and an imperturbable serenity

in place of his natural mobility. Such was the sole aim of his life; for, though despairing of the possibility of attaining scientifically certain knowledge, he never assailed the validity of moral obligations. This explains how the Eleans made him high-priest, and after his death raised a statue to him beside the agora, exempting on his account all philosophers from taxes; how his disciple Timon so highly extols his 'divine repose of soul,' comparing him to the 'imperturbable sun-god,' and how Cicero regards him as Socratic. Nothing is cited as written by P. except a poem addressed to Alexander; and the works of Timon being lost, our knowledge of P. comes mainly from Diogenes Laertius, Sextus Empiricus, Eusebius, Aulus Gellius, and Cicero. See C. Mallet, *Études Philosophiques* (2 vols., 1837-38).

Pyrrhus, king of Epirus, was born about 318 B.C. His father Alcides, the cousin of Olympias (q. v.), had become king of Epirus on the death of her brother Alexander in 326, and P. himself, after chequered fortunes, finally secured the throne in 295. His career first becomes important in 281, when the Tarentines, against whom the Romans had declared war, in the name of all the Greeks of Italy, offered him the command of their forces. In 280 he set sail for Tarentum with 20,000 foot, 3000 horse, 2000 archers, 500 slingers, and 20 elephants, Milo, one of his generals, having preceded him with 3000 men. He at once shut up the theatres and other public resorts of the giddy and licentious Tarentines, and forced their youth to serve in his army. He then met the Romans under the consul M. Valerius Laevinus, at the river Siris, near Heraclea. The battle was long and bloody, both armies advancing and recoiling seven times, and finally only the charge of the elephants broke the Roman ranks. P. himself declared that another such victory would force him to return without a soldier to Epirus. Lucania was now lost to Rome; the Bruttians, Lucanians, and Samnites, with all the Greek cities, joined P. at once. But not a single Latin, even of those captured at the Siris, could be induced to desert the Romans. So sagacious a soldier as P. could not be blind to the peril of his situation. Accordingly, while he himself advanced into Campania, Cincas, the Thessalian rhetorician, his confidential minister, was despatched to Rome with an offer of peace, on condition of all the Greek cities being freed, and their territory being restored to the Samnites, &c. The Senate wavered, but the blind and grey-haired consular Appius Claudius persuaded them to give the proud reply, that Rome could never negotiate while foreign troops were on Italian soil. P. now advanced to Anagnia, within 40 miles of Rome, but the closed gates of all the Latin towns, and two consular armies dogging his steps, with a third in the city preparing for battle under the dictator, forced him to retreat, after doing nothing, into Campania, and thence to Tarentum, where he wintered. In the spring of 279 he advanced into Apulia, and met the Romans near Asculum. P. was again victorious, but with heavy loss. He was wounded himself, and finally had to retire into winter quarters at Tarentum. At this point came a request from the Sicilian Greeks for aid against the Carthaginians, the Syracusans offering P. their sovereignty. In 278 he embarked, leaving Milo in Tarentum, and Alexander, his own son, in Locri. In Sicily, too, he gained victories; and in 276, with Carthage humbled, Sicily all but Lilybæum in his power, with Tarentum securing him a footing in Italy, and his newly-created war-fleet in the harbour of Syracuse, his dream of universal conquest seemed likely soon to be realised. But his Oriental-Hellenistic ideas of ruling cost him his popularity in Sicily; the Carthaginians again landed a strong army, and in the same year he was fain to cross into Italy, his chivalrous spirit prompting him to retrieve, if possible, the misfortunes which had befallen his allies after his scarcely honourable desertion of them. A sea-fight with the Carthaginians during his passage cost him many vessels, and the 20,000 infantry and 3000 horse whom he landed at Tarentum were not the experienced veterans of former days, nor did the Italians hail him with their former enthusiasm. Near Beneventum, a skilful stratagem of P.'s miscarried, a division of his army having lost its way, and the consul Curius Dentatus was thus enabled totally to defeat him. P. in despair now returned to Epirus, leaving a garrison in Tarentum, and after a short war with Antigonus Gonatas gained complete possession of Macedon. He next declared war against Sparta, and, invading the Pello-

ponnesus, was slain at Argos in 272. P. was a general of rare genius, perhaps the most humane and chivalrous soldier of ancient times, a statesman of wide views and keen insight; but he was too compassionate, too honourable, and too unable to restrain his proud and vehement spirit to succeed in his great ambition of conquering the civilised world.

Pyrus is a genus of *Rosacea* consisting of about forty species of deciduous-leaved trees and shrubs, natives of the temperate and cold regions of the northern hemisphere, chiefly in Europe and Central Asia. Several are in very extensive cultivation. Under the section *eu-P.* are included the apple and pear; under *Sorbus*, the service, the rowan, and the white-bean; and under *Mespilus*, the medlar, all of which have separate articles.

Pythagoras, the celebrated Greek philosopher, was born, according to Isocrates, at Samos. His father, Mnesarchus, was a merchant or a signet-engraver, and P., probably born about 570 B.C., certainly flourished in the time of Polycrates. Pherecydes of Syros, Bias, Thales, Anaximander, &c., are stated to have been his teachers, and very probably the first really was so. P. is said to have travelled widely, learning geometry from the Egyptians, arithmetic from the Phoenicians, astronomy from the Chaldeans, religious formulæ and ethical maxims from the Magians, and getting other religious and scientific information even from the Arabians and Indians. Very likely he did visit Babylon and Egypt, but his philosophy and institutions were thoroughly Greek, and not even his doctrine of Metempsychosis must necessarily be ascribed to Eastern or Egyptian teaching. Returning to Samos after, it is said, thirty years of travel, P. found that the despotism of Polycrates there made it utterly impossible for him to realise his great scheme of obtaining a 'religious ascendancy in connection with a certain mystical religious system.' Settling eventually at Crotona, he speedily gained wide influence and very many adherents, chiefly from among the wealthy and noble. 300 of these formed a select brotherhood, somewhat like that of Loyola, bound together by oath, and subjected to a rigid ethico-religious regimen embracing the minutest details of everyday life. After passing an examination as to fitness, in which P. is said to have trusted much to his physiognomical penetration, the candidate had to endure a long probation of mute obedience and unconditional submission to the doctrine taught. All were bound rigorously to examine themselves daily, to be moderate in attire and food, especially animal food, to propagate the school doctrines among the people, and to keep profoundly secret from the uninitiated all that was done within the pale of the society. Among the 300 there were gradations, the division being usually described as one into *Esoteric* and *Exoteric*, though these terms themselves are probably late. All were instructed in ethics and religion, especially the doctrine of Metempsychosis—P. himself is said to have held that his soul had once been that of the Trojan Euphorbus—in mathematics (P. is said to have discovered the propositions of Euclid I. 47, III. 31), arithmetic, astronomy, music, and gymnastics. The specially *esoteric* teaching may have had reference to the orgies or more secret religious doctrines and usages, prominent features of the Pythagorean system. All the members had probably common meals, and there were other outward peculiarities of an ascetic kind, as well as a number of secret conventional symbols for mutual recognition. Among the less intimate adherents of P. were some women. Their whole discipline produced in the Pythagoreans a lofty serenity and self-possession, a devoted attachment to one another, and a boundless reverence for their master (*cf.* the well-known phrase *autos epha, ipse dixit*). P. thus more than anticipated Plato, for he realised his idea in a society which for a time had great influence, and was even to some extent a type of the great moral society of the Christian Church. But just as their ruling idea of *Number* (see below) implied unity of plan and a calculating architect in the physical universe, so in the social system it led them to make supreme the principle of order, authority, and subordination, of conservatism as opposed to free and equal individualism. Oligarchical, thus, both by social position and principles, the Pythagoreans conceived an unbounded scorn for all the uninitiated, and thus inevitably came into collision with the democratic element so powerful in the Greek colonies of S.E. Italy. In the war between Sybaris and Crotona, the Pythagorean Milo commanded the Crotoniates, and under him Sybaris was totally

destroyed (510 B.C.). This so elated the Pythagoreans that they became harsher than ever towards the commons, till finally the latter attacked them while assembled in the house of Milo, and set fire to the building. Only the younger and more active members escaped. This blow was immediately followed by the universal suppression of the Pythagorean clubs as political organisations, though for religious observances and scientific pursuits the Pythagoreans were long united as a sect. P., according to some, perished with the rest; according to others, he fled first to Tarentum and thence to Metapontum, where he starved himself to death (504 B.C.), and where his tomb was shown in Cæsar's time. According to Aristotle, the central doctrine of P. was that *Number* is the essence of all things, and the organisation of the universe in its various determinations is a harmonious system of numbers and their relations. Number here is calculated number, not mere succession of units; it is almost synonymous with the 'law' of modern physicists. It is the method of operation of mind, or *logos*, 'an inner, invisible, moulding, formative principle, something which cannot be conserved as objective or material, in place of the 'sensible universal' of the Ionic schools. To P. as the late Professor Butler says, the universe 'was a living arithmetic in its development, a realised geometry in its repose.' P. was thus the great prophet and anticipator of modern scientific processes, 'first calling the world *cosmos*,' a manifestation to sense of the everlasting order, and bringing the philosophical mind of his age into an entirely new position. As Hegel says, 'he first made thought and not sense the criterion of the essence of things.' Such a philosophy was truly metaphysical; it was hardly theological, as Professor Blackie calls it. Schopenhauer rather is right in styling it 'entscheidener Pantheismus,' but he is unjust in saying that the greatness of P. was due to what he learned, rather than to what he thought, echoing the sneer of Heraclitus that P.'s wisdom was 'eclectic and nothing better than polymathy and perverted art.' Connected with this doctrine of number was that of the *monas* (or *peras*, 'the limited'), the identity or feature of agreement in things, and the *aoristus dyas* (or *apeiron*, 'the unlimited'), the capacity of infinite diversity in things. From the combination of these two results corporeal substance. On the same fundamental idea P.'s theory of music was worked out. The Pythagoreans regarded fire as the noblest element, the enlivening principle of the universe, and accordingly their *cosmos* consisted of ten spheres (a counter-earth (*antichthon*) being supposed to complete the number), circling round a central fire. 'Their mutual distances were supposed to be arranged on a harmonic scale, hence in their calm, well-ordered courses waves of sound were sent forth according to the ratios of their intervals in space, whereby a mighty harmony was evolved.' The soul, also described as a number or harmony, as far as it is the life principle, emanated from the great central fire. There are in it two elements—a rational and an irrational, and the five senses (connected by the Pythagoreans with the five elements) are its instruments; but the only certain knowledge comes from number and its relations. The ethics of the Pythagoreans consisted more in ascetic practices, and maxims for restraint of the passions than in scientific theory. What they had of the latter was always clothed in the dress of mathematics. Virtue was the harmony or health of the soul, and Metempsychosis was regarded as a purification (*catharmos*), a means to attain this. The celebrated Pythagoreans of whom we have notices appear always to have been men of great uprightness, conscientiousness, and self-restraint. No writings of P., if he ever did write anything, have survived. Philolaus, probably a contemporary of Socrates, was the first to publish the Pythagorean doctrines in writing, and Aristotle gives many extracts from his works. Plato, Herodotus, Porphyrius, and Iamblichus also give us information. See Ferrier's *Works*, vol. i.; Ueberweg's *History of Philosophy*, vol. i.; Archer Butler's *Lectures on Ancient Philosophy*; Blackie's *Howa Hellenica*.

Pythæas of Massilia in Gaul, a celebrated Greek navigator, probably a contemporary of Alexander the Great, said to have voyaged 334 B.C. from his native city to Cantium (now Kent), and from thence to Thule (q. v.), afterwards relating his adventures in his work *On the Ocean*. In this or another voyage P. coasted along the whole of Europe from Gadeira (Cadiz) to the

'Tanaïs' (for which he probably mistook the Elbe), and visited the 'Amber-land,' which, according to Ukert, was the Cimbrian Peninsula, or Denmark. P. appears to have been the first to determine the latitude of a place by the sun. Certain fragments of his work called *Periplus* or *Periplus* have been collected and annotated by Arwedson (Upsala, 1824) and Schmekel (Merseburg, 1848). In modern times the voyages of P. have been discussed by many writers, as Adelung, D'Anville, Barth, Forster, Mannert, but especially Lelewel in his *Entdeckungen der Karthager und Griechen im Atlantischen Ocean* (Berl. 1831), and Strazewicz, in *P. de Marseille et la Géographie de son temps* (Par. 1836; Ger. by Hoffman, Leips. 1838). See also Fuhr, *De Pythea Massiliensi* (Darmst. 1835); Redslob, *Thule: Die phönizischen Handelswege nach dem Norden* (Leips. 1855); Bessel, *Ueber P. von Massilien* (Gött. 1858); Ziegler, *Die Reise des P. nach Thule* (Dresden, 1861).

Pythian Games, The, whose foundation was ascribed to Apollo, were held every fifth year on the Crissean Plain, a little to the S.W. of Delphi. Restricted originally to musical contests, they also embraced from 586 B.C. horse, chariot, and foot races, gymnastic exercises, &c. The prize was a chaplet of laurel and a palm-branch, with permission to the victor to erect his statue on the plain. It is certain that the P. G. were still celebrated in the reign of the Emperor Julian (360-63 A.D.), and they were probably discontinued about the same time as the Olympic Games, *i.e.*, 394 A.D.

Pythōn, the name given to various serpents of the family *Boide*, or that of the Boas. They are innocuous, and have no poison-glands, but attain a large size, and their immense muscular power enables them to crush the animals imprisoned in their folds. The halves of the lower jaw are united simply by ligament, and the lower jaw can be separated widely from the skull—two arrangements which serve to largely increase the capacity of the mouth. The pythons first crush their prey into a shapeless, sodden mass, which is swallowed slowly and gradually. But there is little doubt that many of the stories told of their swallowing large prey are simply exaggerations. The tail bears two rows of scales on its under surface. The pythons inhabit India. The *P. molurus*, or common rock snake of India, is a typical genus. The name is also indiscriminately applied to the Boas themselves. The Hortaia, or *P. Natalensis*, is the rock snake or P. of S. Africa.

Pyx (Gr. 'a box'), in the ancient Church, was an ark or wooden vessel kept beside or on the altar, for holding the remains of the consecrated elements after the celebration of the Eucharist, which were reserved for particular uses, and which were also kept sometimes in the silver dove which was suspended over the altar as a symbol of the Holy Ghost. A later name for the P. was the *ciborium* (Gr. a 'cup' or 'bowl' wider at the bottom than at the top). The ciborium-shape, in gold or silver, is the form of the P. still used in the Roman Catholic Church.

Pyx, Trial of the. From each 'journey' weight (15 lbs. troy for gold, and 60 lbs. troy for silver) of metal coined at the Royal Mint, the master of the Mint selects one coin and deposits it in a pyx (Gr. *pyxis*) or chest, kept in the Pyx Chamber at Westminster, and all the coins so deposited are, according to the terms of the Coinage Act of 1870, annually tested as to weight and fineness by ten jurymen (freemen of the Goldsmiths' Company), who are summoned by Treasury warrant, and presided over by the Queen's Remembrancer. This scrutiny is called the T. of the P. Although known to have been ordered as early as the reign of Henry II., the trial was first systematically established by the Mint Indenture of 18 Edw. III.; but prior to 1871 it was conducted at irregular intervals. The coins are weighed to see if they fall within the legal 'remedy' (see MINT) as to weight, and several of them are then melted into an ingot, which is assayed side by side with standard trial plates to test the fineness; some of the remaining coins are also individually assayed. The results of the trial are embodied in a verdict which, when favourable, discharges the Mint authorities from further liabilities, and is published as a guarantee of the intrinsic value of the coinage.

Q.

the seventeenth letter of the English alphabet, occupying the same place as in Latin, and corresponding to the archaic Greek *koppa* and the Semitic *koph*. It is properly a guttural mute, of the same series as K, C, and G, but with a more distinctly guttural sound. In Greek, *koppa* was dropped altogether at an early date in the history of the alphabet, and in Latin also there was a tendency towards the disuse of Q, as may be seen in the use of *cujus* for *quojus* and *cum* for *quum*. In Latin Q was always followed by U, so that the two together may be regarded as constituting a single letter. The same is the case in the Romance languages derived from the Latin, as well as in English; but in French the U is not suffered to modify the pronunciation. In Oriental tongues, such as Arabic, Q retains its proper sound as distinguished from K; the 'Koran' is accurately written *Quran*. The most common change of Q is with its cognates C and K, and sometimes with G in the middle of words: as Lat. *æqualis* = Fr. *égal*. There is another regular interchange with p and t: Lat. *quinque* = Gr. *pente*; *equus* = *hippos*; *quatuor* = *tettara*. As an abbreviation Q stands for *quintus*, and for *que*, in the phrase S.P.Q.R. = *senatus populus que Romanus*. In English law, Q.C. = Queen's Counsel, and Q. B. = the Court of Queen's Bench.

Quadragesima (Lat. 'fortieth,' scil. *dies*) is the first Sunday of Lent (q. v.), which in the 6th c. was extended to 40 days, and was called the Quadragesimal fast.

Quadrangle, an open square court with four sides. Large public buildings, such as palaces, colleges, universities, &c., usually inclose a Q., which is in many cases cloistered round wholly or partially.

Quadrant, the fourth part of a circle, or the arc subtending one right angle. A graduated Q. was the most usual form of the apparatus for ascertaining the altitude of the stars till the present c., when it was superseded by the Mural Circle (q. v.). Hadley's Q. is made upon the same principle as the Sextant (q. v.).

Quadratic Equation, in algebra, is an equation in which the square of the unknown quantity enters as the highest power. Its general form is

$$ax^2 + bx + c = 0$$

where x is the unknown quantity, and a , b , and c are constants. The general solution is

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

If $c = 0$, x has the two values 0 and $-\frac{b}{a}$; if $b = 0$, x has the

values $\pm \sqrt{\frac{c}{a}}$; and if $a = 0$, the equation degenerates into a simple equation of one unknown. See EQUATIONS.

Quadrature, in mathematics, is the operation of determining the area of a given surface, or of finding a square whose area is equal to that of the assigned surface. The areas of figures bounded by straight lines are easily deducible; but the majority of curvilinear figures present difficulties which cannot be surmounted by ordinary geometry, and which in many cases are beyond even the power of the calculus. In analysis, Q. is applied to the process of approximating to the value of a given integral, which cannot be determined exactly; and hence the practical rules of mensuration, gauging, engineering, &c., are such cases of Q.

The Q. of the circle is one of the famous problems of antiquity, ranking with the trisection of the angle, the duplication of the cube, and the perpetual motion. The last is contrary to all experience. See PERPETUAL MOTION, THE. The trisection and the duplication are problems of pure mathematics, which depend upon the solution of a cubic equation, and are therefore irresolvable by the simple geometry of the straight line and circle. They can both be solved, however, if it be allowed that a conic may be described with a given focus and disectrix. To find a simple expression for the side of the square which is equal in area to a given circle, or even to express it in a finite form, has hitherto proved beyond the power of the highest analysis. The incommensurability of the circumference and diameter of a circle is demonstrable, and was suspected by Euclid and the ancient geometers, to whom it was also known that the area of a circle was equal to the product of the radius and semi-circumference. See CIRCLE.

Quadrienn'ium U'tile, a term of Roman law, adopted into that of Scotland, denoting four years allowed after majority to one who had been a minor, under guardianship, to call his guardian to account.

Quadrilateral, in mathematics, is any figure bounded by four right lines. If the sides lie in one plane, the Q. is *plane*; if in different planes, *gauche*. A remarkable property of all quadrilaterals, whether plane or gauche, is that the six lines joining the points of bisection of the sides form a parallelogram with its diagonals.

In fortification, the word is technically applied to four fortresses, which, though not connected directly, are placed so as to mutually protect each other.

Quadrille, a popular set of square dances consisting of five movements, *Le Pantalon*, *L'Été*, *La Poule*, *La Pastourelle*, and *Le Finale*. Popular melodies and selections from the lighter opera form the basis of most quadrilles.

Quadrivium (Lat. *quatuor* 'four,' and *via* a 'way') was a name used by the medieval schools of the West in their classification of the liberal arts. These were seven in number, corresponding to the seven days of the week, viz., grammar, dialectic, rhetoric, arithmetic, geometry, music, and astronomy. The first three, or *Trivium*, a number adopted in honour of the Trinity, were taught in the elementary (*Trivial*) schools; the last four, recalling to mind the four rivers of Paradise, formed the higher course of instruction. The mnemonic line, *Lingua, Tropus, Ratio, Numerus, Tonus, Angulus, Astra*, enumerates the subjects first of the Trivium, then of the Q. The following two were used as giving definitions also:—(1) *Gram. loquitur; Dia. verba docet; Rhe. verba ministrat*; (2) *Mus. canit; Ar. numerat; Ge. ponderat; As. colit astra*.

Quadru'mana (Lat. 'four-handed'), a name given by Cuvier to the order of *Mammalia* represented by the various kinds of monkeys and apes, from the fact that the hinder feet become hand-like in function. The name must, however, be accepted with the qualification that the feet of an ape are really feet, and are only functionally like hands. The function of hands is performed by the feet of the Q. on account of the peculiar disposition of the toes. The great toe can be 'opposed' more or less perfectly to the other toes so as to permit of objects being seized or grasped by these members. In modern systems of Mammalian classification, the order Q. is made to form a subdivision of the order *Primates*. This latter group includes man and apes, and the association of the human and quadrumanous forms is justified by their close structural affinities. The

Bimana, or division including man, would be separated from the quadrumanous group of the Primates by the fact of the foot never becoming prehensile in man, whose *hallux* or great toe exists in the same plane as his other toes.

Quadrupeds ('Four-footed'), a name popularly used as synonymous with *Mammalia* (q. v.). If, however, it be used in this sense, it must be borne in mind that all mammals have not four limbs. The whales, dolphins, and their kind have only the fore limbs. The name Q. is not of any zoological importance. If used in any scientific sense, it might be employed to designate those fishes which have pectoral and ventral fins, and all other vertebrate animals in which four limbs are developed.

Quæstor (from Lat. *quæro*, 'I seek') was the name given to two distinct classes of Roman officials. The *quæstores parricidi*, two in number, were first appointed in the regal period. In 366 B.C. their functions of prosecuting persons accused of murder, and executing the sentence given, was transferred to the *Triumviri capitales*, and the name Q. was henceforth restricted to the officers entrusted with the care of the public money (Q. *classici*), who were not elected till after the kingly period, and were also two in number till 421 B.C., when other two were added, and the office was opened to plebeians, though none obtained it till 409 B.C. Henceforward the consuls during war were always attended by one Q. each, who sold the booty, and acted as paymasters. The two who remained at Rome (*urbani*) superintended the treasury as before. In 265 the number of quæstors was again doubled to eight, one being always after this appointed to see to the corn supply of Rome (*quæstura ostiensis*). Sulla in his dictatorship raised the number to 20, and Julius Cæsar had at one time even 40. Ex-quæstors became members of the Senate.

Quagg'a (*Equus quagga*), a species of *Ungulate* quadrupeds belonging to the group *Solidungula* (q. v.), or that including the horses and asses. The Q. is nearly allied to the Zebra (q. v.), but is not striped on the limbs. Its colour is a dark or blackish brown on the head, the tints on the back and hind quarters being lighter. The body is banded with darker markings, and the tail is tufted. The Q. is smaller than the zebra. It is gregarious, but the herds are said to mingle indiscriminately with those of the zebra. The name is derived from the cry of the animal.

Quaglio, a Munich family of Italian extraction, fourteen of whose members have distinguished themselves in the annals of art. Its founder, Giulio Q., born at Laino, on the Lago di Como, in 1601, studied painting under Tintoretto, and was ennobled by the Emperor Leopold I. His son and namesake (died 1720), painted some fine frescoes at Vienna and in Laibach Cathedral, and left a son (Giovanni-Maria (1700-65), who devoted himself to architecture at Milan, and filled the post of imperial engineer-in-chief. Giovanni's sons, Domenico (1723-60) and Lorenzo (1730-1804), were the one an historical painter, the other court-architect at Munich; and of Lorenzo's three sons, Giulio (1746-1801), Giuseppe (1747-1828), and Giovanni-Maria (1772-1813), the two first were court-architects, the last an architect, painter, and engineer. Giuseppe, again, had four sons—Angelo (1778-1815), a celebrated lithographer; Domenico (1786-1837), the reviver of architectural painting in Germany, and author of *Sammlung merkwürdiger Gebäude des Mittelalters in Deutschland* (2 vols. Karls.), *Ansichten merkwürdiger Gebäude in München* (2 vols. Mün. 1811), &c.; Lorenzo (1796-1869), a talented genre painter; and Simone (1795-1878) who was succeeded by his son Angelo (born 1829) in the office of Court scene-painter at Munich. Francesco (born 1844), a brother of the last, has produced some admirable genre and battle-pieces.

Quail (*Coturnix*), a genus of *Rasorial* birds, including various species. The Q. resembles the Partridge (q. v.) in general form, but wants the naked red space seen over the eye in the latter bird. The tarsi do not bear 'spurs' in the Q., and the tail is short. The wings are rounded, and the first quill is as long as the other feathers of the wing. The Common Q. (*C. dactylosomus*) occurs in Europe generally, in N. Africa, India, and China. It arrives in Britain in May, and migrates southwards in October. The male comes first, and appears to cry for its mate in a peculiar whistling tone, by the imitation of which it is sometimes snared. The average length of the Q. is about 3 inches. It is of a dusky brown colour, variously marked and

mottled with black and with darker shades. The males are said to exceed the females in numbers, and the statement that the birds are polygamous must therefore be received with some degree of reservation. The eggs vary in number from six to twelve, and are of a light greenish hue. Quails are captured in immense numbers on the shores of the Mediterranean Sea, during their migrating flights. They were celebrated in classical times, 'Q. fights' being an amusement of the Greeks and Romans. Other species are the Coromandel (*C. testilis*) and *C. Argoandah* or the Rock Q. of Deccan. The Virginian or American Q. is the *Ortyx Virginianus*, a bird belonging to a different genus from that of the European Q. The American Q. is common in N. America. It attains a larger size than its European representative. The Andalusian Q. (*Turnix tachydromus*) inhabits both sides of the Mediterranean Sea, and belongs to a distinct genus.

Quakers. See FRIENDS, SOCIETY OF.

Quaking Grass (*Brisa*) is the name of a small genus of handsome grasses with panicles of many-flowered compressed pendulous spikelets suspended on hair-like pedicels. They are met with in temperate districts of Europe, Asia, and Africa, and are familiarly represented by *B. media*, a common European and British species of pastures and heaths; it is not, however, of much agricultural importance. *B. maxima* and *B. minor* are frequently cultivated in gardens as ornamental annual plants, the last named reaching English soil as a native plant.

Quamash, the Indian name for *Camassia esculenta* of the natural order *Liliaceæ*, occurring in great abundance in swampy plains of N.-W. America, where the bulbous roots form a very important article of food for the natives, and are extensively cultivated by them. After roasting, they are either dried or pounded and made into cakes, and preserved for winter use.

Quantic, in the higher algebra, is generally understood to be any rational integral homogeneous function of two or more variables, but includes also non-homogeneous functions which may be supposed to have resulted from substituting unity in place of one or more of the variables of a homogeneous function. Quantics are classified according to their dimensions. Thus, $ax^2 + by^2$ is of two dimensions in the variables, and is called a *quadratic*; and similarly we have *cubics*, *quartics*, *quintics*, &c., denoting quantics of the third, fourth, fifth, &c., degrees. Further, quantics are distinguished as *binary*, *ternary*, *quaternary*, &c., according as they contain two, three, four, &c. variables. Thus a ternary quintic is a rational integral and homogeneous function of the fifth degree in three variables. See Salmon's *Higher Algebra*, and the numerous memoirs of Cayley, Sylvester, and other analysts.

Quantification of the Predicate. In Aristotle's system of logic four kinds of propositions are recognised—the universal affirmative, the universal negative; the particular affirmative, and the particular negative. Of these, the following may be taken as types: All A is B, i. e. A is B, some A is B, some A is not B. For more than two thousand years this system was accepted with little or no modification. Within the last half-century, however, it became apparent that a reform was necessary in order to make the syllogism an absolutely rigid system of logical deduction. The improvement was effected nearly contemporaneously by various writers, but notably by Sir William Hamilton and Professor De Morgan. The reform was, in the language of Hamilton, to *quantify the predicate*—that is, to state distinctly whether the whole or only a part of the predicate is considered in the proposition. For example, in the proposition all A is B the subject only is quantified; and it would be illogical to conclude that all B is A. All we can be sure of is that some B is A. If, however, we say that all A is all B, we at once quantify the predicate; and now the simple converse, all B is all A, is true. It appears, then, that by quantifying the predicate we may break up the ordinary universal affirmative into two; namely, all A is all B, and all A is some B. Treating the others similarly, we obtain eight propositions instead of four.

- | | |
|---------------------|--------------------------|
| 1. All A is all B. | 5. Some A is all B. |
| 2. All A is some B. | 6. Some A is some B. |
| 3. No A is any B. | 7. Some A is no A. |
| 4. No A is some B. | 8. Some A is not some B. |

Of these, 4 and 8 are perhaps never used; and 2 is evidently the simple converse of 5, as 4 is of 7. When the predicate is thus quantified the process is much simplified, being merely a transposition; and the laws of the syllogism assume a corresponding simplicity. Hamilton maintained that in thought the predicate was always quantified as well as the subject. Certain logicians, however, have taken exception to this, and have urged that the peculiar forms of expression are not only unusual, but are really never used, so that there is no logical ground for believing that *in thought* the predicate is quantified. Again, some of the propositions are really equivalent to two, that the proposition all A is all B contains in a compressed form the two ordinary propositions all A is B, and all B is A; whereas, it is maintained, logic seeks to analyse our thoughts into their simplest elements, and not to express them in a condensed form. See Hamilton's *Discussions and Lectures on Logic*, and Mill's *Examination of Hamilton's Philosophy*.

Quaquaversal (Lat. 'turning every way') is the name given to strata which dip to or from a single point, so as to form a dome-like elevation or a basin-shaped depression. This kind of dip is produced by a local upheaval or subsidence.

Quarantine (Fr. *quarantaine*, 'a period of forty days') is an international regulation, by which neither persons nor goods in a vessel coming from a place where a contagious or infectious disease prevails, is permitted to land till a certain period, generally forty days, has elapsed without the suspected disease showing itself. By 6 Geo. IV. cap. 78 the Privy Council may order vessels to repair to certain places to be examined so as to determine their liability to Q. Masters of vessels liable to Q. are to hoist a yellow flag on meeting other vessels at sea and on coming within two leagues of the United Kingdom, under the penalty of £100. Where Q. is established, it is a high misdemeanour for any person to come on shore, or to disembark any goods from the suspected ship. Various regulations and restrictions, all more or less oppressive, have been and still are enforced in the matter of Q. in Spain, Portugal, Greece, and Turkey. Since 1866, four international sanitary conferences have been held, and at one held at Vienna in 1873 a resolution was carried, by a large majority, in favour of abolishing Q. regulations in Europe on rivers; but it was decided to continue the system by sea. In English law, Q. denotes the forty days during which the widow of a deceased landowner may remain in the chief house of the estate until her dower be assigned to her.

Quarles, Francis, was born in 1592 at Romford, Essex. He studied at Christ's College, Cambridge, and Lincoln's Inn, became cupbearer for a while to the Queen of Bohemia, and in 1621 went to Dublin, where he was appointed secretary to Bishop Usher. After several years he returned to England, was appointed chronologer to the City of London, and devoted himself to literary labours. His first published work was *A Feast for Wormes in a Poem on the History of Jonah*, with *Pentecostia*, or *the Quintessence of Meditation* (1620). In 1621 appeared *Hadassa, or the History of Queen Esther*, and soon after Q. published *Argalus and Parthenia*, founded on Sidney's *Arcadia*. These poems were written in decasyllabic couplets. Next came *Job Militant, with Meditations Divine and Moral*, and *Sion's Elegies, Wept by Jeremie the Prophet* (1624). In 1625 there followed *An Alphabet of Elegies*, and *Sion's Sonnets, sung by Solomon the King, and Periphrased*; and a collection of his pieces, entitled *Divine Poems*, was printed in 1630. Two years later came *Divine Fancies, Digested into Epigrammes, Meditations, and Observations*. The quaintest and most truly poetical of Q.'s works, the *Emblems, Divine and Moral*, was brought out side by side with the *Emblems of Wither* (1635; new ed. 1877). The *Emblems* follow a fashion traced back to the great Italian lawyer, Andrea Alciati, and seem specially inspired by the *Pia Desideria* of the Jesuit Herman Hugo. They are distinguished by fantastical expression, sometimes by pathos, often by bathos, and are best described as conceits. Q.'s next work was *Hieroglyphics* (1638). In 1641 he collected a number of short essays and aphorisms into a volume entitled *Enchiridion of Meditations*. This book is full of pithy maxims, often overstrained; every sentence contains an antithesis, like a nut with two kernels. In the Civil War, Q. espoused the cause of Charles I., and gave offence to the Parliament in *The Loyal Convert*; and having joined the king at Oxford, he lost all his property, even his

books. He was twice married, and had eighteen children by his first wife. He died 8th September 1644, overwhelmed with troubles. After his death were published *Solomon's Recantation, a Paraphrase on Ecclesiastes*; *The Virgin Widow* (a feeble comedy); and *the Shepherd's Oracles*.

Quarrel or **Quarry** (Fr. *carreau*, from *carre*, 'to square'; Lat. *quadrare*) signifies, in architecture, any square-shaped opening, and it also denotes a diamond-shaped pane of glass, or a square tile or paving-stone. A flat square-headed arrow-bolt for a crossbow was also known as a Q. or *quarrell*.

Quarry, an open excavation, whence stones for building and other purposes are procured. Although quarrying is essentially the same as Mining (q. v.), a mine differs from a Q. in being a subterranean working, always at a considerable depth. Where stone or slate is obtained from underground, the place becomes a mine in the official sense, and comes under the cognizance of the mine inspectors. Quarries were worked by the nations of antiquity, and the huge monoliths which the Egyptians succeeded in raising and transporting to great distances especially mark the great skill in quarrying possessed by them. Quarries of limestone, sandstone, granite (syenite), and red porphyry opened by the Egyptians are still exposed to view, and many of them contain half-quarried colossal blocks, bearing marks of the quarrymen's tools. The most celebrated quarries of ancient Greece were situated at Mounts Pentelicus and Hymettos, and in the Islands of Paros, Scio, Samos, and Lesbos; and with the beautiful white marble obtained from them, the Parthenon and other famous temples were constructed. The Pentelic and Parian marble quarries have recently been reopened. The travertine (*lapis Tiburtinus*) of which Rome is chiefly constructed has been quarried at Tivoli and its neighbourhood since the commencement of the Christian era; and the famous Carrara quarries, from which supplies of white statuary marble are still drawn for the whole world, were first opened in the reign of Augustus.

The operations of quarrying differ as the rock to be excavated is stratified or unstratified, and its intended use. In extracting whinstone for road-metal, or limestone to be burnt, for example, the most expeditious mode of detaching the rock, viz., by Blasting (q. v.), is resorted to. In quarrying building-stones, on the other hand, hand labour is preferred to blasting, for waste is thereby avoided. In stratified quarries the largest stones are detached and slid upon their *bed* by driving wedges into a series of picked holes on the natural face of the rock; but where the stratum is very thick, wedges are also driven in in a line parallel to the bedding. In sandstone quarries, having several beds of different and serviceable qualities, it is usual to lay out the beds in a series of steps, called bench or stage working, so that the excavation of the beds may be simultaneously carried on. Roofing-slates, though bedded, are more easily split with a broad chisel and hammer in the direction of its *cleavage* lines, which are often at right angles to the bedding. Unstratified rocks are usually quarried on a perpendicular face in hillsides, and in detaching the stones advantage is always taken of natural divisions or fissures, or of any peculiarity of structure, as the columnar forms of basalt, or the tabular and cuboidal forms of granite. All stones are generally roughly dressed or squared with the pick before leaving the Q.

Numerous quarries of sandstone, magnesian and common limestone, marble, granite, basalt, porphyry, roofing-slate, &c., constitute one of the sources of wealth of the United Kingdom. A revised table (first drawn up in 1839 by the commissioners for selecting a suitable stone for the Houses of Parliament) of the building-stone quarries is appended to Professor Hull's *Building and Ornamental Stones* (Lond. 1872). See also *Mine Inspectors' Report* for 1875.

Quart, a measure of capacity, being the fourth part of a gallon. It contains two pints. See GALLON.

Quartan Fever. See AGUE.

Quarter is the fourth part of anything. It is used as a definite standard measure of mass, when it is equivalent to 28 pounds avoirdupois, or the fourth part of a hundredweight. As a measure of capacity, it contains 8 bushels, or 32 pecks. In this latter sense its derivation is doubtful, but it is supposed to be of Norman origin.

Quarter, in heraldry, one of the ordinaries, or subordinaries, now superseded by the *Canton* (q. v.).

Quarter, in war, is to spare the life of a defeated enemy, an essential element in modern civilised warfare. The expression is an ancient one and its derivation uncertain. 'That every one should kill the man he caught, and keep no Q.,' Drayton's *Miseries of Queen Margaret*. According to De Brieux, a Q. was the portion of pay promised as ransom by soldiers to their conquerors in battle.

Quarter Days. These are, in England and Ireland, Lady Day, 25th March; Midsummer Day, 24th June; Michaelmas Day, 29th September; and Christmas Day, 25th December. House-rents are generally made payable quarterly, but if there is no stipulation as to time of payment, rent is only due once a year. See *LANDLORD AND TENANT, NOTICE TO QUIT*. In Scotland the legal terms are Whitsunday, the 15th of May, and Martinmas, the 11th of November; and if nothing is said regarding date of entry and payment of rent, Whitsunday is understood as regards houses, but by custom 25th May has come to be the day. Entry to arable land is at Martinmas. Rents and interests in Scotland fall due on 15th May and 11th November.

Quarterdeck, the part of the uppermost deck of a ship between the main and mizzen masts, where there is a poop, or between the mainmast and stern if otherwise. It is the parade on Her Majesty's ships. The Quarter of a ship is the after-part of its side, about one-fifth in extent of the entire length of the vessel.

Quartering, in heraldry, a method of Marshalling (q. v.) by dividing a shield into four parts by two lines, fess-wise and pale-wise, meeting in the centre, a distinct shield being allotted to each quarter. In the Q. of two coats the more important is placed in the first and fourth quarters, and in the case of three coats, the fourth quarter repeats the charge of the first, as on the shield of Queen Victoria, where England occupies the first and fourth, Scotland the second, and Ireland the third. Four coats of arms are placed in their proper order of succession, one in each quarter. In the Q. of any number greater than four, the number of lines drawn pale-wise is increased, and in the case of an odd number of coats being represented, the last quarter is always a copy of the first. The earliest English example of marshalling by Q. is the shield on the monument of Alianore, Queen of Edward I., in Westminster Abbey, bearing the arms of Castile and Leon, first quartered by her father Ferdinand III. on the union of those crowns. Symon de Montagu is the first subject on record who bore quartered arms (1311). By the end of the 14th c. marshalling by Q. had become a common fashion.

Quartermaster, Military and Naval. A quartermaster is attached to every regiment of cavalry, battalion of infantry, and brigade of artillery. His duties are to look after the quarters, clothing, rations, ammunition, stores, &c. of the troops. He holds the rank of lieutenant, and his pay varies from 4s. 8d. per day in the marines to 9s. 6d. in the Life Guards. In the cavalry it is 8s. 6d., rising after ten years' service to 12s., and in the infantry 6s. 6d., rising to 10s. A non-commissioned officer is usually promoted to the post. A quartermaster-sergeant assists the regimental quartermaster in his duties. The quartermaster in the navy is a petty officer who attends to the stowage of ballast and provisions, the steerage of the ship, &c.

Quartermaster-General is one of the principal staff officers in the British army, whose department is charged with the arrangements as to marching, billeting, quartering, embarking and disembarking of troops, strategical and topographical subjects, military questions as to barracks, hospitals, canteens, lights, fuel, cooking, &c. He has a sub-department in the Military Department of the War Office, and acts under the Adjutant-General. His salary is £1500. He has the assistance of an Assistant Q.-G. A Deputy Q.-G., an Assistant Q.-G., and several Deputy-Assistant Quartermaster-Generals are attached to the Intelligence Branch of the department whose functions include the preparation and maintenance of information regarding the defence of the empire and the mobilisation of the army, the collection of foreign army statistics, the charge of maps, plans, &c., and the translation of foreign documents, &c.

Quartern, the name given in some parts of Great Britain to the fourth part of a peck, or the fourth part of a pint. The Q. loaf is so called because it contains a fourth of a stone of flour, or about 4 lbs.

Quarter Sessions, the General Court of, is held in England by two or more justices of the peace, in every division of a county, once every quarter of a year, to try offenders against the peace. By 1 Will. IV. c. 70, these sessions, in the several counties, ridings, and divisions, are held in the first week after the 11th October, in the first week after 28th December, in the first week after 31st March, and in the first week after the 24th June. But justices may direct the April Q. S. to be held any time between March 7th and April 22d, so as not to interfere with the spring assizes. The sentences of any court of Q. S. take effect from the time of being pronounced, unless the court otherwise direct. Judges of Q. S. are unpaid. It has, however, been found expedient to appoint a paid officer to assist in their work. He is called a *Recorder* (q. v.). In Scotland, justices of the peace meet at the county town on the first Tuesdays of May, August, and March, and on the last Tuesday of October. At these quarterly courts they have the power of reviewing sentences passed at the occasional meetings of justices, called special or petty sessions, when the sentence is subject to review.

Quarter-Staff, a tough wooden stave about 8 feet long, formerly used by the English in attack or defence. It was grasped in the middle with one hand, and between the middle and the end with the other, and a twirling motion having been given to it, strokes were dealt with either end alternately. Q.-S. encounters are frequently described in the Robin Hood ballads; and down to last century sport with the Q.-S. was one of the chief amusements at English rustic games.

Quarters, Military and Naval, (1) apartments in military stations for accommodation of officers and men. The rules regarding officers' quarters will be found in the Queen's regulations; (2) the stations of a ship's crew on entering into action.

Quartet', Quartette', or Quatuor, a musical composition in four parts, or for four voices or instruments. Instrumental quartets are usually written in complete symphony form, containing four movements and sometimes an introduction. Two violins, a viola, and a violoncello are used for string quartets. One of the earliest string quartets was composed by Allegri about 1650. Haydn, Mozart, Beethoven, Schubert, Schumann, Onslow, &c., have enriched this form of composition.

Quartodecimans (Lat. *decimus quartus*, 'fourteenth') were those Christians, chiefly in the Eastern Church, who in the controversy which arose in the 2d c. respecting the time and mode of keeping Easter (q. v.), maintained that Christ ate the Jewish Passover with his disciples on the evening of the 14th Nisan, and was crucified on the 15th, as represented by the first three Gospels, in opposition to those in the Western Church, who maintained that he was crucified on the 14th, appealing in support of their opinion to the fourth Gospel.

Quartz, the generic name of all minerals which are composed of silica. It is a constituent of many rocks and composes most pebbles. It is colourless when pure, but presents a great variety of tints of yellow, green, red, blue, brown, &c., and is often marked with stripes or bands. It is of all degrees of transparency to opacity, and occurs coarse and radiated, or fine granular, or compact. The crystallisation is rhombohedral, and the six-sided prisms in which the mineral usually occurs are terminated by six-sided pyramids, and are in other respects often peculiarly modified. Notwithstanding the variety of forms which it assumes, it is readily recognised by its hardness, its infusibility before the blow-pipe, its insolubility in acids, and the absence of any cleavage. The varieties of Q. naturally fall into three groups. The *vitreous* varieties are distinguished by their glassy fracture. To this group belong Rock-crystal, Amethyst, Rose Q., False Topaz, Smoky Q., Milky Q., Prase (a leek-green massive mineral), Aventurine Q. (spangled through with golden scales of mica), and Ferruginous Q. The *chalcidonic* varieties have a sub-vitreous or waxy lustre, and are usually translucent. See *CHALCEDONY*. The *jaspers* varieties are opaque, and have a doubtful glimmering lustre.

Jasper, Bloodstone, Lydian Stone, and Float Stone are the best known varieties.

Q. Rock is a light grey, reddish, or brown rock, compact in texture, and consisting chiefly of *Q.* It has resulted from the action of heat upon sedimentary sandstones. It is also known as Quartzite.

Quasimodo Sunday is the first Sunday after Easter, so called from the first words of the Introit of the mass for the day (1 Peter ii. 2), and otherwise called *Dominica in Albis*, from the practice in the ancient church of those who had been baptized at the preceding Easter giving up their white garments (*albes*) in the churches on that day.

Quass, or **Kvass**, a kind of beer made in Russia, and prepared from rye grain. *Q.* is also employed as vinegar by allowing the fermentation to continue until the material turns sour.

Quassia is a genus established by Linnæus in commemoration of a Surinam negro, who was notorious about 1760 for the cures of fever he effected by what is now called *Q. amara*, a native of that country. It is a shrub with beautiful crimson flowers, and has been introduced into hothouses. The *Q.* of materia medica is now, however, derived from *Picramnia excelsa* (also belonging to the natural order *Simarubaceæ*), common in the plains and lower mountains of Jamaica. It grows to the height of 60 feet, forms a spreading tree, and in appearance somewhat resembles the ash. The wood is intensely bitter, for which reason an infusion, extract, and tincture are used as a powerful tonic, chiefly employed in dyspepsia. Although prohibited by law, it is said to be frequently substituted by brewers for hops. On animals it appears to act as a narcotic poison, causing its use as an insecticide, and furniture made from it is insect-proof. Water allowed to remain in cups turned from it in a short time acquires tonic properties. *Quassia lignum* of the chemists consists of its yellowish-white chips, and the neutral principle on which the bitterness depends is called *quassin*. The names bitter-ash and bitter-wood are applied to the tree.

Quaternions, the name given by Sir W. R. Hamilton of Dublin to his new calculus, owes its immense power as a mathematical method to the importance which it attaches to *direction* as a fundamental conception. At the very outset two distinct kinds of quantities are recognised—directed quantities and undirected quantities. The simplest conception of a directed quantity is a straight line drawn in a particular direction from a given point. Such a line, when both its magnitude and direction are considered, Hamilton calls a *vector*. All undirected quantities, such as are employed in ordinary analysis, he distinguishes as *scalars*. A scalar, in fact, is neither more nor less than a number in its widest algebraic sense. In ordinary analytical geometry, a line drawn from the origin is fixed both in direction and magnitude when the co-ordinates of its other extremity are known. Here its direction is absolutely determined; but it is determined only indirectly through its relations to three arbitrarily chosen axes, and is kept distinct from the other leading conception of magnitude. Hamilton took the straight line as he found it, referred none of its properties in space to any arbitrarily chosen lines, but combined the conceptions of direction and magnitude into the one idea of vector. Since a vector is then fully determined in accordance with ordinary geometrical notions by the three co-ordinates of its further extremity, which co-ordinates are scalars, it follows that a vector involves three scalar quantities. We shall return to this point when we come to consider the nature of a *quaternion*. Meanwhile, as well-known examples of vectors, we may mention velocities, accelerations, forces, fluxes, &c., all of which are readily recognised as directed quantities. It is customary to symbolise vectors by the Greek letters, reserving the Roman letters for scalar quantities. In defining a vector, no notice is taken of its *position* in space, but simply of its direction and magnitude. Hence two equal and parallel straight lines are represented by the same vector symbol; and conversely a given vector may be drawn from any point, since it remains the same vector as long as its direction and magnitude are kept constant. Further, any two lines in space which are not parallel cannot be the same vector—thus, different radii of a sphere or circle, though equal in magnitude, must be represented by different symbols when they are considered as vectors. The addition of vectors is already familiar in dynamics under the name of the com-

position of velocities and forces. They are combined in precisely the same manner. Thus the vector $\alpha + \beta$ (for the sum of a number of vectors is always a vector) is the diagonal of the parallelogram whose sides are α and β ; or it is at once obtained geometrically by drawing the vector β from the extremity of α , when the vector from the origin to the extremity of the new β is the sum $\alpha + \beta$. In the same way it is readily shown that the sum of the vectors OA, AB, BC, CD , taken in order, is the vector OD . Hence the sum of the vector sides of any polygon taken in order must equal zero. Thus in the triangle ABC the sum of the vectors AB, BC, CA is zero; and remembering that the sum of the vectors AB, BC is the vector AC , we conclude that we may consistently regard the vector AC as being equal to *minus* the vector CA . In other words, reversing a vector is equivalent to changing its algebraic sign, or $+\alpha - \alpha = 0$. As long as α and β are really different vectors, the vectors $\alpha + \beta, \alpha - \beta$ are also distinct. These latter, indeed, are the diagonals of the parallelogram whose sides are α and β . Should $\alpha = \beta$, however, $\alpha + \beta = 2\alpha$, and $\alpha - \beta = 0$. The number 2 is here a scalar quantity; its effect, when α is multiplied by it, is to alter the magnitude without altering the direction. By employing a proper scalar factor, then, we may alter the *length* of a vector at will; and any two parallel vectors of different lengths may be expressed by the same vector symbol, multiplied, however, by a different scalar. To apply the foregoing principles to a simple geometrical theorem, let it be required to prove that the diagonals of a parallelogram bisect each other. Let the vector $OA = \alpha$, $OB = \beta$. Complete the parallelogram $OACB$. Join OC and AB . Then the vector $OC = \alpha + \beta$, and $AB = AO + OB = -\alpha + \beta$. Let D be the point where the diagonals intersect, then OD is a multiple of $OC = p(\alpha + \beta)$, say. Similarly AD is a multiple of $AB = q(\beta - \alpha)$, say.

From the figure it is evident that the various vectors are related by the equation

$$AD = AO + OD \\ \text{or } q(\beta - \alpha) = -\alpha + p(\alpha + \beta).$$

Transposing, this becomes

$$(q - p)\beta + (1 - q - p)\alpha = 0.$$

This is of the form $b\beta + a\alpha = 0$, where, if α and β are two different vectors, a and b must each be zero, since it is impossible to undo by moving in the direction β what has been already done by moving in the direction α . Hence, if $b\beta + a\alpha = 0$, $b = 0$, and $a = 0$; so that in the particular case above we obtain the two equations

$$q - p = 0 \\ \text{and } 1 - q - p = 0.$$

Solving, we find $p = q = \frac{1}{2}$; and therefore the diagonals of a

parallelogram bisect each other. Consequently, the vector from the vertex of a triangle to the point of bisection of the base is half the sum of the vectors which represent the sides, all the vectors of course being drawn from the vertex. Take now any quadrilateral, $ABCD$, which may be plane or gauche. Take the vectors of its corners with reference to any origin O , and let $\alpha, \beta, \gamma, \delta$, be the vectors OA, OB, OC, OD . Bisect AB in P , BC in Q , CD in R , and DA in S . The vectors of these points of bisection are respectively $\frac{1}{2}(\alpha + \beta)$, $\frac{1}{2}(\beta + \gamma)$, $\frac{1}{2}(\gamma + \delta)$, and $\frac{1}{2}(\delta + \alpha)$. Hence

the vector $PQ = PO + OQ = -\frac{1}{2}(\alpha + \beta) + \frac{1}{2}(\beta + \gamma) = \frac{1}{2}(\gamma - \alpha)$. Similarly $QR = \frac{1}{2}(\delta - \beta)$, $RS = -\frac{1}{2}(\gamma - \alpha)$, $SP = -\frac{1}{2}(\delta - \beta)$, from which we see at once that PQ is equal

and parallel to RS , and QR equal and parallel to SP , and that therefore the lines joining the points of bisection of the sides of any quadrilateral in space form a parallelogram. This example indicates the ease with which *Q.* attacks problems in three dimensions. We have seen that, to alter the length of a given vector, we have simply to multiply by the proper scalar factor. The value of this scalar depends upon the unit of length we have chosen, and should the given vector be a *unit* vector, i.e., a vector whose length is unity, the scalar multiplier gives the

length of the new vector. Hence any vector a may be written $TaUa$, where Ta is the length or *tensor*, as Hamilton called it, of the vector a , and Ua is the unit vector in the same direction.

Generally, then, to pass from one vector to another which is parallel to it requires simply the introduction of a scalar multiplier to change the tensor. But how must we operate so as to change the direction of a vector; in other words, what operation will transform a into β , where a and β are different vectors? The simplest way to conceive of this transformation is to draw a and β from the same point, and then rotate a about an axis perpendicular to the plane in which the two vectors lie until it coincides with β . In establishing a new calculus, we may take any convenient and unambiguous symbol to represent this operation of rotation; and Hamilton has chosen for it a very simple and suggestive form; the quotient, namely, of the two vectors. The equation

$$\frac{\beta}{a} \cdot a = \beta \quad \text{or} \quad \beta a^{-1} \cdot a = \beta$$

defines this quotient. $\frac{\beta}{a}$ is not a scalar; for multiplication by a scalar does not alter the direction of the vector, but only the length, while this operator alters both. Nor is it a vector; it is a *quaternion*, and was so named by Hamilton because it depends on *four* numbers. For when by rotation a is made to coincide in direction with β , we have to consider not only the magnitude of the angle through which a is rotated, but also its *plane*, or the direction of the axis of rotation. A rotation, then, is fully known when we know its amount or angle, and the direction of its positive axis. But to fix the direction of a line requires two numbers, and therefore a rotation involves three. Having brought a into coincidence with β , there is still another operation necessary so as to alter the tensor of a and make it equal in length to β . The quaternion, then, which transforms the vector a into the vector β , depends upon four numbers, the numerical ratio which alters the tensor, the magnitude of the angle of rotation, and the *two* elements which determine the direction of the axis of rotation. A quaternion may be regarded as composed of two operators, which may be considered separately and applied in succession. The first simply alters *length*; the second alters *direction*. These Hamilton called respectively the tensor and versor of the quaternion; and their relation is given by the equation

$$q = TqUq$$

where q is any quaternion, Tq its tensor, and Uq its versor. A similar formula we saw to exist for a vector, where, however, U signified unit vector. There is, however, no ambiguity occasioned by employing the same symbol for two apparently different ideas, for a unit vector is a right versor, *i.e.*, a versor whose angle is a right angle.

If we have three rectangular unit vectors i, j, k , the versor $\frac{k}{j}$, which transforms j into k , may be equated to i , the unit vector perpendicular to them both. Hence

$$ij = \frac{k}{j}j = k; \text{ or } i, \text{ considered as an operator, rotates } j \text{ through a right angle in the positive direction till it coincides with } k. \text{ Operate again by } i; \text{ then, since } k \text{ is situated in a precisely similar manner to } i \text{ as } j \text{ is, it is also rotated in the positive direction through a right angle. Hence we have the equation}$$

$$iij = ik = -j$$

or

$$i^2 = -1.$$

The square of a unit vector or of a right versor is a scalar, and is equal to negative unity. By symmetry we have also

$$\begin{aligned} jk &= i & kj &= -i \\ ki &= j & ik &= -j \\ ij &= k & ji &= -k \end{aligned}$$

$$i^2 = j^2 = k^2 = ijk = -1.$$

These equations contain the whole theory of Q . The product of two rectangular vectors is a third vector perpendicular to both; and the product of two parallel vectors is a scalar, for $aa = aba^2 = -ab$, where a is a unit vector and a and b are scalars. But what is the product of two vectors which are other-

wise related? Take two vectors, a and β , inclined to each other at an angle θ . The vector β may be split up into two other vectors, one of which is parallel to a and the other perpendicular to a . To avoid unnecessary complication, we shall take a and β as unit vectors. Hence the two projections of β are $a \cos \theta$ and $\gamma \sin \theta$, where γ is the unit vector perpendicular to a in the plane containing $a\beta$, the vector OC in the figure, and $\cos \theta$ and $\sin \theta$ are of course scalar multipliers. We may then write

$$\begin{aligned} \beta &= a \cos \theta + \gamma \sin \theta \\ a\beta &= a^2 \cos \theta + a\gamma \sin \theta \\ &= \cos \theta + \delta \sin \theta \end{aligned}$$

and therefore

where δ is the unit vector perpendicular to a and γ . Multiplying β into a , the equation becomes

$$\begin{aligned} \beta a &= a^2 \cos \theta + \gamma a \sin \theta \\ &= \cos \theta - \delta \sin \theta. \end{aligned}$$

The product of any two vectors, then, consists of two parts, a scalar part ($\cos \theta$) and a vector part ($\delta \sin \theta$). Its value, then, depends upon *four* scalars, and again we have a quaternion. To pass from unit vectors to other vectors, we simply have to multiply throughout by the scalar product $TaT\beta$; and then the equations take the form

$$\begin{aligned} a\beta &= -TaT\beta \cos \theta + TaT\beta \delta \sin \theta \\ \beta a &= -TaT\beta \cos \theta - TaT\beta \delta \sin \theta \end{aligned}$$

where a, β are not now unit vectors, but where δ is still the unit vector perpendicular to their plane. Hamilton writes the above equations symbolically thus

$$\begin{aligned} a\beta &= Sa\beta + Va\beta \\ \beta a &= S\beta a + V\beta a \end{aligned}$$

where $Sa\beta$ means the scalar portion of the product and $Va\beta$ the vector portion. Comparing with the original equations, we have the following identities:—

$$\begin{aligned} Sa\beta &= -TaT\beta \cos \theta, & Va\beta &= +TaT\beta \delta \sin \theta \\ S\beta a &= -TaT\beta \cos \theta, & V\beta a &= -TaT\beta \delta \sin \theta \end{aligned}$$

and therefore $Sa\beta = S\beta a$, $Va\beta = -V\beta a$

and further

$$\begin{aligned} 2Sa\beta &= a\beta + \beta a \\ 2Va\beta &= a\beta - \beta a. \end{aligned}$$

The scalar of the product of any two vectors is the product of their tensors into the cosine of the angle between their directions; and the vector is the product of the tensors into the sine of the angle into the unit vector perpendicular to the plane of the two original vectors. $TVa\beta$, or the tensor of this vector, evidently represents the *area* of the parallelogram whose sides are the vectors a, β , and therefore twice the area of the triangle contained by these sides. $SaU\beta$ is the projection of the vector a in the direction of the unit vector $U\beta$. One marked peculiarity of Q lies in the non-commutative character of its products— $a\beta$ does not equal βa , nor does $a^{-1}\beta$ equal βa^{-1} .

Consider the triangle ABC , where vector $AB = a$, vector $BC = \beta$ and vector $AC = \gamma$. Then

$$\begin{aligned} \gamma &= a + \beta \\ \text{squaring, } \gamma^2 &= (a + \beta)(a + \beta) \\ &= a^2 + a\beta + \beta a + \beta^2 \\ &= a^2 + 2Sa\beta + \beta^2 \end{aligned}$$

$$\text{or } -(T\gamma)^2 = -(Ta)^2 - (T\beta)^2 - 2TaT\beta \cos \theta$$

$$\text{or } AC^2 = AB^2 + BC^2 + 2AB \cdot BC \cos \angle ABC$$

a well-known formula.

$$\begin{aligned} \text{Again, since } \gamma &= a + \beta \\ a\gamma &= a^2 + a\beta \end{aligned}$$

an equation between two quaternions. But if two quaternions are equal, their scalar portions must be equal to each other, as also their vector portions, since it is impossible for a scalar to be equal to a vector. Hence the above equation contains two equations—

$$Sa\gamma = a^2 + Sa\beta,$$

and $Va\gamma = Va\beta$ (for a^2 is a scalar). Taking tensors, we have

$$\begin{aligned} TaT\gamma \sin \angle CAB &= TaT\beta \sin \angle ABC, \\ AC : BC &= \sin \angle ABC : \sin \angle CAB, \end{aligned}$$

or

a fundamental theorem in trigonometry. The scalar of two rectangular vectors is zero, and conversely $Sa\beta = 0$ requires that a be perpendicular to β , since, when $\cos \theta = 0$, $\theta = \frac{\pi}{2}$ or

Indeed, as we before saw, the product of two rectangular vectors is a vector perpendicular to both.

In applying Q , to the geometry of lines and surfaces in space, we must take a symbol to represent the variable vector. Let ρ then be any vector from the origin to the curve or surface. We shall discuss briefly what certain quaternion equations represent.

$$T\rho = c \text{ (a constant)}$$

means that however we draw OP , its tensor is always the same. The surface is therefore a sphere. Squaring, and remembering the $(T\rho)^2 = -\rho^2$, we have the transformation $\rho^2 = -c^2$. This then is the equation to a sphere whose centre is at the origin. Let the centre be at the extremity of the vector α , then the equation becomes

$$T(\rho - \alpha) = c,$$

$$(\rho - \alpha)^2 = -c^2,$$

$$\rho^2 - 2S\rho\alpha + \alpha^2 + c^2 = 0.$$

This is a quadratic equation, and therefore ρ has two values, or a line drawn from the origin cuts a sphere in two points. From the theory of equations we see that the product of the tensors of the vectors of these points is $(T\alpha)^2 - c^2$, a constant quantity. In other words, if OPQ be the line from the origin O intersecting the sphere in P and Q , the product $OP.OQ = \text{constant}$, a well-known property of the sphere or circle.

The equation $S\rho\alpha = 0$ represents a plane passing through the origin and perpendicular to α , because in whatever direction ρ is drawn it must be perpendicular to α , and its tensor is unlimited. The equation to any parallel plane is $S\alpha(\rho - \beta) = 0$, where β is the vector to any given point in the plane.

Similarly the equation $V\rho\alpha = 0$ represents a straight line parallel to α , and the equation of any other parallel line is $V\alpha(\rho - \beta) = 0$, where β is the vector to any point upon it. This last equation may be cast into the form $V\rho\alpha = \gamma$ where $\gamma (= V\alpha\beta)$ is a constant vector. The form $TV\rho\alpha = c$ includes this case, but has a wider meaning. Put into ordinary geometric language, it means that the area of the triangle, whose sides are α and ρ , is constant for all values of ρ , which is therefore the vector of any point upon a right cylinder whose axis is α .

Any vector ρ may be expressed in terms of the rectangular unit vectors i, j, k in a way closely resembling Cartesian methods. If we measure the unit vectors i, j, k , along the axes X, Y, Z , and if we draw the vector ρ to the point P , whose ordinary co-ordinates are x, y, z , we have

$$\rho = xi + yj + zk.$$

Squaring, we obtain

$$\rho^2 = x^2i^2 + y^2j^2 + z^2k^2 + xy(ij + ji) + yz(jk + kj) + zx(ki + ik).$$

But, as was shown above, $i^2 = j^2 = k^2 = -1$, and

$$ij = -ji, jk = -kj, ki = -ik, \text{ and therefore}$$

$$-(T\rho)^2 = \rho^2 = -x^2 - y^2 - z^2.$$

Or the square of OP is equal to the sum of the squares of the co-ordinates. If $\rho^2 = -c^2$, a constant, we get at once the ordinary equation to a sphere

$$x^2 + y^2 + z^2 = c^2.$$

Take any other vector

$$\rho_1 = x_1i + y_1j + z_1k$$

Then

$$\begin{aligned} \rho\rho_1 &= xx_1i^2 + yy_1j^2 + zz_1k^2 \\ &+ (xy_1 - x_1y)ij + (yz_1 - y_1z)jk + (zx_1 - z_1x)ki \\ &= -xx_1 - yy_1 - zz_1 \\ &+ (xy_1 - x_1y)k + (yz_1 - y_1z)i + (zx_1 - z_1x)j \end{aligned}$$

since $ij = k$, &c. Here, again, the dual character of the quaternion $\rho\rho_1$, as made up of a scalar and a vector, is evident.

$$S\rho\rho_1 = -xx_1 - yy_1 - zz_1 = -rr_1 \cos \theta$$

where rr_1 are the tensors of $\rho\rho_1$ and θ the angle between their directions.

$$V\rho\rho_1 = (xy_1 - x_1y)k + (yz_1 - y_1z)i + (zx_1 - z_1x)j$$

and therefore

$$\begin{aligned} TV\rho\rho_1 &= \sqrt{-(V\rho\rho_1)^2} \\ &= \sqrt{(xy_1 - x_1y)^2 + (yz_1 - y_1z)^2 + (zx_1 - z_1x)^2} \\ &= rr_1 \sin \theta \end{aligned}$$

also a well-known formula. From these examples, the simplicity of the quaternion expression as contrasted with the ordinary analytical form is evident; and not only is the notation simpler, but it is infinitely more suggestive. Great as are the advantages gained in pure geometrical investigations, the tremendous power of quaternions is best displayed in physical applications. We cannot do more than point out a few of the more striking cases.

And first it must be remarked that differentiation of quaternions and vectors presents no new difficulty, provided the non-commutative character of multiplication be borne in mind.

Take for instance the equation to the circle

$$\rho^2 = -c^2 \text{ or } \rho\rho = -c^2$$

Differentiating, we obtain

$$\rho d\rho + d\rho\rho = 0$$

$$\text{or } S\rho d\rho = 0$$

since $d\rho$ is itself a vector, the vector namely which added to the original ρ gives the new contiguous ρ . It is therefore the vector which joins the extremities of two infinitely near vectors to the curve. In other words, it is in the direction of the tangent at the point, and the equation $S\rho d\rho = 0$ proves that in a circle the tangent is at right angles to the radius. In dynamics, where time is the independent variable, instead of the symbol $d\rho$, Newton's fluxion expression $\dot{\rho}$ is adopted. Evidently, if ρ is the vector of a moving point, $\dot{\rho}$ is its velocity, and $\ddot{\rho}$ its acceleration. If the acceleration $\ddot{\rho}$ is in the direction of ρ , as is the case with all central orbits, then $V\rho\ddot{\rho} = 0$. In co-ordinate geometry, the equivalent of this simple form is the group of equations

$$x\ddot{y} - \dot{x}\dot{y} = 0$$

$$y\ddot{z} - \dot{y}\dot{z} = 0$$

$$z\ddot{x} - \dot{z}\dot{x} = 0.$$

Consider again the trinomial expression for ρ , namely,

$$\rho = xi + yj + zk.$$

The operator

$$i \frac{d}{dx} + j \frac{d}{dy} + k \frac{d}{dz}$$

performed upon any function, scalar or vector, differentiates it in the direction of ρ . Repeated twice, it gives the operator

$$\left(i \frac{d}{dx} + j \frac{d}{dy} + k \frac{d}{dz} \right)^2$$

and the scalar portion of this is $-\frac{d^2}{dx^2} - \frac{d^2}{dy^2} - \frac{d^2}{dz^2}$, a well-known operator in the mathematical theory of potential. Writing $i \frac{d}{dx} + j \frac{d}{dy} + k \frac{d}{dz} = \nabla$, the quaternion form of Laplace's equation

$$\frac{d^2\phi}{dx^2} + \frac{d^2\phi}{dy^2} + \frac{d^2\phi}{dz^2} = 0$$

where ϕ is a given function is

$$S\nabla^2\phi = 0.$$

The directness with which Q attacks all problems depending upon polarity in space is its great recommendation. It has done away with the artificiality of choosing arbitrary axes, and has given a definite meaning to the old imaginary of algebra, the root of minus one. $\sqrt{-1}$ is any unit vector in space; and hence Demoivre's theorems in analytical trigonometry are really quaternion forms. We have done no more than give the barest elements of the subjects, and have but touched upon the nature of a quaternion. For a fuller discussion, reference must be made to the various treatises on the subject. Hamilton's *Lectures on Q.* (1853), and his *Elements of Q.* (1866) are of course the first and foremost of these. The latter is, in its range and method, undoubtedly one of the most remarkable and original works ever written. It is perhaps too full as an introduction to the science; but as a compendium it is invaluable. Tait's *Treatise on Q.* (1867, 2d edition, 1872) is much shorter, and is chiefly confined to problems which bear upon practical or physical questions. Kelland and Tait's *Introduction to Q.* (1873) is elementary, and intended for beginners. Clifford's *Elements of Dynamic* (1878) is purely quaternionic in its treatment, and quaternion conception enters into Clerk Maxwell's *Electricity and Magnetism* (1873) and his small elementary work on *Matter and Motion* (1876).

Quathlam'ba, or **Kahlam'ba**, a lofty and rugged mountain-range forming a portion of the great dividing chain sometimes called in its entirety the 'backbone of S. Africa.' The Q . range divides Nomansland and Natal from Basutoland, and attains a height of 8000 to 10,000 feet. It is of interest ethnologically, as forming the line of separation between the Bechuana tribes of the interior and the Kaffir tribes inhabiting the coast region.

Quatrain (Fr. from *quatre*, 'four'), in poetry, is a stanza of four lines, which usually rhyme alternately, although sometimes

the first and fourth and the second and third rhyme together. A perfect Q. is very rare, for not only must the thought expressed be completed within the limits of four lines, but the facile turn of the epigram is to be avoided. The French poets furnish the best examples of the Q.; Landor's are perhaps the most graceful in the English language.

Quatre Bras (Fr. 'four arms'), a farm in Belgium, province of S. Brabant, 10 miles S.S.E. of Waterloo (q. v.), so called because near it the road from Charleroi to Brussels crosses that from Namur to Nivelles. Q. B. is famous as the scene of a bloody battle between the French under Ney and the English under Wellington (16th June 1815), in which the former lost 4140, the latter 5200 men.

Quatrefages de Bréau, Jean Louis Armand de, was born at Berthezene, near Valleraugue, February 10, 1810. In 1833 he was appointed assistant professor of chemistry at Toulouse, and there he published two treatises, *Recherches d'Embryogénie sur les Limnées et les Planorbes* (1834), and *Recherches sur les Axodontes* (1835). This last work led to his appointment as professor of zoology at Toulouse in 1838. In 1840 he threw up his post, went to Paris, and there pursued his studies, contributing with pen to the *Revue des Deux Mondes*, and with pencil to the *Règne Animal Illustré*. In 1852 he was appointed professor of natural history at the Henri IV. Lyceum, and was elected member of the Academy of Sciences. Five years after, he renounced the natural history chair at the Lyceum for that at the Museum. Q.'s popular works have nearly all passed through the *Revue des Deux Mondes* in serial form. The records of a scientific expedition, thus published, were collected under the title of *Souvenirs d'un Naturaliste* (2 vols. 1854), and translated into English (*Rambles of a Naturalist*; Bohn, 1857). Other contributions to the *Revue* specially worthy of mention are *Métamorphoses de l'Homme et des Animaux* (1855-56), and *L'Unité de l'Espèce Humaine* (1860-61). Q.'s most purely scientific articles were contributed to the *Annales des Sciences Naturelles* and the *Institut*. His various essays on *Les Mollusques Philobentérés*, detailing the modifications of the digestive and circulatory systems of these animals, raised a discussion in which the greatest of European naturalists took part; and in the end Q. triumphed. Q. made many voyages in pursuit of his science, the most noted being that undertaken in company with Milne Edwards and Blanchard. They explored the coasts of Sicily between Trapani and Catania. Q.'s results were published under the title of *Recherches Anatomiques et Zoologiques faites pendant un Voyage en Sicile* (1855). The Academy of Sciences commissioned him to inquire into the diseases of silkworms, and in 1859 he produced *Études sur les Maladies Actuelles des Vers à Soie*, a work followed in 1860 by *Nouvelles Recherches sur les Maladies Actuelles des Vers à Soie*. In 1862 he published *Métamorphoses de l'Homme et des Animaux*; in 1869, *Histoire de l'Homme*; in 1870, *Charles Darwin*; in 1871, *La Race Prussienne*; in 1875, *Crania Ethica*.

Quatrefoil (Fr. *quatre-feuille*), in architecture, a panel or piercing, of any form, divided into four leaves or lobes by Cusps (q. v.), or featherings.—In heraldry, a Q. is a charge representing a four-leaved grass without a stalk. When represented with a stalk, it is called Q. *slipped*.

Quatremère, Étienne Marc, was born at Paris, July 12, 1782. When a child he plunged into study, and throughout his whole life he cared for men much less than books. In 1807 he was employed in the manuscript department of the Imperial Library; in 1809 he obtained the chair of Greek literature at Rouen; in 1815 he succeeded Porte-Dutheil in the Academy of Inscriptions; in 1819 he became professor of Hebrew, Chaldean, and Syriac in the College of France; and in 1827 he changed this chair for that of Persian in the school of living Oriental languages. Such were the events which scarcely interrupted for one day a life entirely given up to scholarship as an end in itself. Q.'s first work was *Recherches sur la Langue et la Littérature de l'Égypte*. Here he proved that the way to the study of ancient Egyptian, and especially of hieroglyphics, lay through the Coptic. In 1810 appeared his *Mémoires Géographiques et Historiques sur l'Égypte* (2 vols.), and of his other writings the chief are *Mémoire sur les Nabatéens* (1835), *Mémoires sur la Topographie de Babylone*, *Mémoires sur*

Darius le Mède, *Histoire des Mongols de la Perse* (1836), *Préface de Ibn-Khaldoun*, *Histoire des Sultans Mameloucks* (translated from the Arabic of Ahmed-Makrizi, 2 vols. 1837-38), *Chrestomathie en Turc Oriental* (1842), and *Mélanges d'Histoire et de Philologie Orientale* (1861). For twenty years he poured treasures of learning into the *Journal des Savants*. He died at Paris, 18th September 1857. Q. was the most learned Orientalist of his day; as to facts he was the most reliable of authorities, because he worked slowly and for the mere delight of reading what others had not read; but his critical powers were feeble, and his opinions in philology too conservative. He would never admit the value of comparative philology, and declared that the use of Sanscrit as a key to Latin, Greek, &c., would be given up, as the similar use of Hebrew in a less enlightened age had been given up. He collected an immense mass of materials for a dictionary of Arabic, but, despairing of ever accomplishing the task of compilation, distributed his information in foot-notes throughout many miscellaneous volumes. He also amassed notes for dictionaries of Coptic, Syriac, Oriental Turkish, Persian, and Armenian. His splendid library of 50,000 volumes was purchased at his death by the king of Bavaria, and is now at Munich. Prefixed to the *Mélanges* is a notice of the author by Barthelemy St. Hilaire.

Quatremère de Quincy, Antoine Chrysostome, second cousin of the preceding, was born at Paris, October 21, 1755. After finishing his education at the college of Louis-le-Grand, he was sent by his parents to study law, but a passion for art developed at school led him to neglect law for architecture and sculpture. In 1776 he went to Italy, and carefully examined the treasures of Rome and Naples. In 1785 appeared his *Mémoire sur cette Question: Quel fut l'État de l'Architecture chez les Égyptiens, et qu'est-ce que les Grecs en ont emprunté?* This performance was crowned by the Academy of Inscriptions, and led to the author's being engaged to write the *Dictionnaire d'Architecture* for Panckoucke's *Encyclopédie Méthodique* (1st vol. 1788), which was followed in 1790 by *Considérations sur les Arts du Dessin en France, suivies d'un Plan d'Académie ou d'École Publique et d'un Système d'Encouragement*. Q. took an active part in the Revolutionary movement, and was for a time imprisoned. In 1815 Q. was elected perpetual secretary and professor of archaeology to the Académie des Beaux Arts, and was charged with the art department of the *Journal des Savants*. In that year he produced *Le Jupiter Olympien, ou l'Art de la Sculpture Antique*, and *Lettres écrites de Londres à Rome, sur les Marbres d'Elgin*. These letters were addressed to Canova. In 1824 Q. edited the letters of Poussin. Among his other works are, *Essai sur la Nature, le But et les Moyens de l'imitation dans les Beaux Arts* (1823); *Histoire de la Vie et des Ouvrages de Raphaël* (1824); *Histoire de la Vie et des Ouvrages des plus Célèbres Architectes du Onzième Siècle jusqu'à la fin du Dix-Huitième* (2 vols., 1830); and *Histoire de la Vie et des Ouvrages de Michel Ange Buonarrotti* (1835). Q. died at Paris on the 28th of December 1849.

Quaver, a musical note,  half the duration of a crotchet and one-eighth of a semibreve.

Quay (Fr. *quai*, Dutch *kaai*, 'a dyke or causeway'), a bank, dyke, or wharf along the side of a river, harbour, dock, or basin, or facing the sea, to which ships are moored while lading or unlading. A Q. is usually constructed of masonry, the retaining wall being strengthened at the back by counterforts at regular intervals, but in America timber quays are common. The dues exacted for the use of a Q. are termed *quayage*.

Quebec, formerly **Lower Canada**, or **Canada East**, a province of the Dominion, second in population to Ontario. It lies on both sides of the St. Lawrence, extending N. towards Hudson's Bay, and is bounded E. by Labrador and the Gulf of St. Lawrence, S. by New Brunswick, Maine, New Hampshire, Vermont, and New York, and S.W. and W. by Ontario, from which it is separated by the navigable Ottawa. Area, 193,355 sq. miles; pop. (1871) 1,191,516. The level country in the St. Lawrence basin, the 'Champaign of Canada,' is confined on the N. by the Laurentian range and on the S. by the chain of Notre Dame, continued by the Green and White Mountains. The great northern hill-region is composed of Laurentian rocks, and is barely habitable, except in the low, fertile valleys, but supplies

a vast quantity of timber. The St. Lawrence in flowing through Q. receives numerous affluents, of which the chief, all in the N. section, are the Saguenay, St. Maurice, Manicouagan, and Outarde. The Saguenay about the middle of its course expands into the great lake of St. John. In the W. there are many other lakes, including the Grand Lake, which is drained by a branch of the Ottawa. The Champaign, though injured by generations of bad tillage, is very productive, yielding wheat, oats, barley, potatoes, buck-wheat, and some Indian corn. The network of streams intersecting the province enables the timber industry to penetrate to the interior; and the spaces cleared are left available for colonization. Some 30,000 men are employed every winter as shanty-men or wood-cutters, while upwards of 4000 horses haul the logs and squared timber to the river banks. In the S. section of Q. and on the S.E. of the Champaign is the wooded hill country called the Seigniories, and still further E. and S. the 'eastern townships,' a series of fertile, populous valleys, between hills densely timbered and bearing copper ores, iron, galena, some silver and gold, various marbles and serpentine, and excellent granites, soapstones, and slates. The Gaspé Peninsula, at the S. of the St. Lawrence mouth, resembles the eastern townships, producing small quantities of gold, petroleum, limestone, sandstone, &c. The climate is generally severe, hot summers alternating with long winters, but on the lower St. Lawrence the summers are more temperate. The valley of the upper Saguenay is sheltered from N. winds, and is one of the most popular districts with recent settlers. Other newly-settled tracts are the valleys of the St. Maurice and Ottawa, part of the Eastern Townships, the Mantapédic valley in the E., and the peninsula of Gaspé. Crown-lands comprise three-fourths of the area, the timber of which is sold by agents, who also sell lands to settlers on easy terms. Small free-grant lands are gifted to actual settlers. The exports, chiefly to Great Britain, the United States, and W. Indies, are timber (\$10,000,000 yearly), fish, fish oils, wool, furs, horses, cattle, hides, grain, flour, and ores. In 1876 there entered the ports 1436 vessels of 1,061,782 tons, and cleared 1499 of 1,070,719 tons. The imports in 1876 amounted to \$35,035,091, and the exports to \$37,876,815. In 1871, Q. contributed 50.26 per cent. of the whole Dominion customs. There were built at the various ports 142 vessels of 27,943 tons in 1876. Internal affairs are under a lieutenant-governor, a legislative council of 24 members, and an assembly of 65 members. The pop. in 1871 comprised 1,019,852 Roman Catholics, who have an archbishop of Q. and five bishops. There is an Anglican bishop of Q. and another of Montreal (metropolitan of Canada). Jacques Cartier entered and named the St. Lawrence in 1535, but the first permanent settlement at Q. was not made till 1608. From 1640 to 1701 the French colonists were engaged almost constantly in encounters with the Iroquois, the allies of the English colonists of what is now part of the United States, and the old enemies of the Algonkins, the allies of the French. The famous war of 1759-60 ended in the surrender of Q. to the English. The Q. Act of 1774 secured civil and religious freedom to the Catholics, and the denunciation of this Act by the Philadelphia Congress alienated the Canadians during the American War of Independence. The jealousies between the English and French colonists arising from differences of religion and race led to the separation of Q. or Canada into E. and W. portions in 1791, and finally to the establishment of the Confederation of 1867.

Quebec, the capital of the province of Q., on the left bank of the St. Lawrence, 250 miles from its mouth, and at its confluence with the St. Charles at Point des Monts, 108 miles N. E. of Montreal by rail. It lies picturesquely between the two rivers, on the N.E. end of a narrow rocky plateau, which for about 8 miles forms the left bank of the St. Lawrence from Cape Rouge. Cape Diamond, the E. end of this promontory, is 333 feet above the river, to which it presents nearly a precipitous face, while the land slopes gently to the St. Charles. Opposite Cape Diamond the St. Lawrence narrows to 1133 yards, but immediately below it expands into a beautiful basin 2500 yards wide, forming a splendid harbour, in which the spring tides rise 18 feet. The magnificent scenery of the district, and the romantic associations of the city, attract tourists from all parts of the world. Some 8 miles off, the Montmorenci, the pride of Q., takes its magnificent leap of 250 feet to the St. Lawrence. Q. consists of an upper

and lower town, the former of which is surrounded by massive walls, and until recently had five highly picturesque gates. The citadel, which occupies about 40 acres on the plateau of Cape Diamond, was originally designed by Vauban, but recast on plans approved by the Duke of Wellington in 1823. Since the erection of the casemated forts at Lévis in 1867-69, and the reception of its armament of rifled artillery, Q. has been regarded as the most strongly fortified town in N. America. It is the seat of a Roman Catholic archbishop and of an Anglican bishop, and has (1877) nineteen churches, of which 7 are Roman Catholic. Several of the churches are interesting buildings, and contain fine pictures by European masters. The public buildings, not excepting the massive pile of the House of Legislature, are of a very commonplace character. Q. is rich in educational and benevolent foundations. Q. Seminary, founded by M. de Laval de Montmorenci, first bishop of Q., in 1663, became, under imperial charter, the Laval University in 1854. The Jesuits' College (1635) has been used as barracks since 1761. The Ursuline convent dates from 1641, the Hôtel-Dieu from 1639, and the General Hospital from 1690. Earl Dalhousie founded the Literary and Historical Society in 1824, and Dr. Joseph Morrin endowed Morrin College in 1860. The lower town, the seat of wholesale commerce and of the shipping trade, is built round the base of Cape Diamond, on a narrow strip reclaimed by the construction of wharves. At the end of some wharves there is as much as 50 feet of water at low tide. On an average 1300 vessels enter the port yearly, and most of these are ocean steamers of large tonnage. In summer three Trans-Atlantic steamers leave Q. weekly. The size of the harbour may be estimated from the fact that it afforded secure accommodation to the Great Eastern in 1861. Extensive harbour-works are in course of construction (1878) at the mouth of the St. Charles. Various manufactures have recently sprung up in the suburbs, but the great industry is still shipbuilding, as many as 30 large ships of from 500 to 2000 tons each leaving the docks in one winter. Opposite Q. are Lévis and South Q., two thriving towns, with which communication is maintained by steam ferries. South Q. is the dépôt of the Grand Trunk Railway. Q. sends three members to the House of Commons at Ottawa. Pop. (1871) 59,699, of whom 52,337 are Roman Catholics, mostly French and Irish Canadians. The fort of Q., founded by Champlain in 1608, was surprised in 1629 by Sir David Keith, and held by the English for three years. Returned along with the Acadian peninsula and Cape Breton, it was unsuccessfully besieged by the English in 1690, but fell in 1759 after the victory of Wolfe on the Heights of Abraham. According to the Père-Lacombe, the name Q. is derived from the native word, *kepák* ('it is closed'); the river here appearing to be closed by Cape Diamond in ascending, and by the Isle d'Orléans in descending.

Quedlinburg, a town of Prussian Saxony, on the river Bode, at the base of the Harz Mountains, 32 miles S.W. of Magdeburg by rail. It is surrounded by a wall with towers and fosses, and has several suburbs. It has eight churches, the finest of which are the Schlosskirche (erected 1021; restored 1862), and the St. Wipertikloster, the oldest Christian building in Saxony. The castle, standing on a lofty sandstone rock, was once the seat of the abbesses of the convent of Q., which was founded by Otto the Great in 937, and attained to great prosperity, but declined after the Reformation, and was suppressed in 1803. The Rathhaus has a fine collection of antiquities and paintings, and the Gymnasium possesses a valuable library. The industries of Q. are dyeing, bleaching, the making of nets and damasks, and the manufacture of machinery, wire-ware, sugar, chemicals, starch, and paper. It has important nurseries and a trade in flower-seeds. Pop. (1875) 17,044. Q., founded by Heinrich I. in 929, was a favourite residence of the emperors of the Saxon line. A Hanseatic town until 1473, it passed then under the protection of the Electors of Brandenburg. It was the birthplace of Klopstock and Karl Ritter, to whom monuments have been erected in the Bruhl Park. See Fritsch, *Geschichte des vormaligen Reichstifts und der Stadt Q.* (2 vols. Quedlinb. 1828); and Ranke & Kugler, *Beschreibung und Geschichte der Schlosskirche der Q.* (1838).

Queen (Old Eng. *cwæn*, from the same root as Goth. *qvens*, Gr. *gynê*, Sans. *gani*, 'a woman,' and therefore identical with *quean*), a title borne by a female sovereign in her own right (Q. regnant), the wife of a king (Q. consort), or the widow of a king

(Q. dowager). In Great Britain and all other monarchies where the Salic Law (q. v.) does not prevail, a Q. regnant enjoys precisely similar dignities and privileges with a King (q. v.), the present Q. resting her title to the crown on the statute of 12 and 13 Will. III. cap. 3, by which the succession was settled on the Princess Sophia of Hanover and the heirs of her body, being Protestants. By the Statute of the Treasons, 25 Edward III., it was rendered treason to compass the death of a Q. consort, or to violate her person. She, if herself charged with treason, may be tried by the peers of Parliament, as Anne Boleyn, or proceeded against by a bill of pains and penalties, as Caroline, the wife of George IV. (See CONSORT.) By 6 Henry VI. no one can marry a Q. dowager, except with the king's permission, on pain of forfeiting lands and goods; and her revenue was fixed by 1 and 2 William IV. cap. 11 at £100,000 per annum.

Queen Anne's Bounty. See BOUNTY, Q. A.'s.

Queen Anne's Farthings, patterns of a coinage of farthings proposed to be issued by Queen Anne, for which high prices have sometimes been paid by collectors, under the mistaken notion that they are extremely scarce.

Queen Charlotte's Islands, a small group in the N. Pacific Ocean, about 80 miles off the coast of British Columbia, and 110 to the N. of Vancouver Island. By far the largest is Graham Island, which has an area of 3000 sq. miles and is 80 miles long. The only other members of the group of any considerable size are Moresby, Prevost, and North Islands. The group, though included in the territory of British Columbia, is little known, and is only sparsely inhabited by Indians of various tribes.—**Queen Charlotte Sound,** a long narrow channel, partly separates Vancouver Island from the mainland, and connects the Gulf of Georgia with the open sea in the N., as on the S. does the Strait of San Juan de Fuca.

Queen Charlotte's Sound, an inlet at the N.E. extremity of the Middle Island of New Zealand, discovered and named by Cook in 1770. It is about 25 miles long, has two entrances divided by a large island, and its shores are hilly, wooded, and indented with numberless bays. The Sound is very deep, and capable of sheltering any number of vessels of the largest size. Near its upper end is the port of Picton, which is connected by railway with the extensive pastoral districts of the interior.

Queen of the Meadow. See SPIRÆA.

Queen's Bench Division of the High Court of Justice. Determinations of the Common Pleas division, and of inferior courts of record in England, may be appealed to this division. Indictments removed into it may be tried either *at bar*, that is, at the bar of the court while sitting in term time, or *at nisi prius*, by a jury of the county out of which the indictment is brought, Queen's Bench having supreme criminal jurisdiction. The court may order indictments moved into the Queen's Bench to be tried at the Central Criminal Court, or order offences committed out of the jurisdiction of that court to be tried by it. See COURTS OF JUDICATURE, SUPREME ACTS.

Queen's College, Cambridge, founded in 1448 by Queen Margaret of Anjou, and refounded by Elizabeth Woodville, wife of Edward IV., in 1465, consists of a president, fourteen fellows, and eighteen scholars. The scholarships, ranging in value from £30 to £75, are tenable for three years, and there are also five exhibitions and various college prizes. Q. C. presents to eleven livings, and in 1878 had 159 members of the Senate, 49 undergraduates, and 257 members on the boards.

Queen's College, Oxford, founded in 1340 by Robert Eglesfield, chaplain to Queen Philippa, in whose honour the college received its name, consists, under the new statutes of 1858, of a provost, eighteen fellows, fifteen scholars, two Bible clerks, and four Eglesfield exhibitions, which last must be natives of Cumberland or Westmoreland. The foundation scholarships are of £90 for five years, the Bible clerkships of £81 for a like period, the Eglesfield exhibitions of £81 for four years, and there are also twenty-four other exhibitions and a Jodrell scholarship (1866) of £100 for four years. Q. C. presents to twenty-five livings, and in 1878 has 245 members of Convocation, 109 undergraduates, and 458 members on the books.

Queen's Colleges, Ireland, established in 1845 to afford the highest education to all religious denominations, were opened in 1849 at Belfast (q. v.), Cork, and Galway. In 1850 the Queen's University was founded at Dublin, with power to confer degrees on students attending these three colleges, and a month later the whole institution was condemned by the Irish Catholic bishops at the Synod of Thurles, on account of its unsectarian character. A supplemental charter, granted in 1866, created much opposition, and was allowed to expire in 1868. Each college has several scholarships of from £40 to £20, and is governed by a president. In June 1878 there were 52 professors at the three colleges, and 886 students, of whom 230 were Catholics. A bill proposing to sectarianise Belfast in favour of the Presbyterian Church, with a view to ultimately making Cork and Galway Catholic colleges, was rejected in the House of Commons by a majority of 206, May 25, 1878.

Queen's Counsel. This is a rank conferred by the crown on certain barristers. It confers precedence and right of precedence over other barristers, the Queen's Counsels ranking among themselves according to their seniority in that rank. There is no salary attached to the office. A Q.C. can only act against the crown by special leave, which is, however, always given, on payment of a small fee. Queen's Counsels are now appointed among the advocates in Scotland.

Queen's County, an inland county of Ireland, province of Leinster, bounded N. by King's County, E. by Kildare and Carlow, S. by Kilkenny, and W. by Tipperary and King's County. Its greatest length from E. to W. is 37 miles, and from N. to S. 33 miles. Its area is 424,854 acres, of which 342,422 acres are arable. The pop. in 1841 was 153,930; but in 1871 it had fallen to 79,771, or scarcely one-half of the former number. 88 per cent. of the pop. are Roman Catholics, and 11 per cent. Episcopalian. The Barrow and its tributary the Nore flow E. and S. through the county. In the W. the Slieve Bloom mountains rise to the height of 1753 feet, while the Dysart Hills in the E. are not so high, but contain some not very deep seams of anthracite coal. Slate, sandstone, and marble are also worked. The manufactures are now confined to coarse flannels and friezes. It is traversed by a branch of the Grand Canal. Oats, barley, and potatoes are grown, together with a little wheat. The average rent of land is 12s. per acre. In 1876 there were 140,977 acres under crops, 218,765 acres in grass, 10,644 acres in plantation, and 54,382 in bog, waste, and water. Q. C. has (1876) 12,536 horses, 75,494 cattle, 91,879 sheep, and 32,626 pigs. Q. C. was anciently included in the districts of Leix on the N. and Ossory on the W., and was principally held by the clan of the O'Mores. After a revolt of the clan in the reign of Mary, the present county was incorporated and received its name in honour of the Queen, as also did its assize-town, Maryborough (pop. 6553). Other towns are Mountmellick, Mountralto, and Portllington. The county has several antiquities, among them a cromlech and rath at Gracfield, and a round tower, almost perfect, at Timalsoc. It returns two members to Parliament.

Queensland, a British colony occupying the N.E. portion of Australia. It has a length from N. to S. of 1300 miles, and a breadth, S. of the Gulf of Carpentaria, of 900 miles. Its coast-line measures 2550 miles, and its area is 669,520 sq. miles, or 34 times that of France. It is bounded on the N. by the Gulf of Carpentaria and Torres Strait, and on the E. by the Pacific Ocean. On the S. it is separated from New South Wales by the Macpherson Range, Dumaresq River, and parallel of 29° S. lat. On the W. it is divided from S. Australia by the meridian of 141° E. long., as far as the 26° parallel of S. lat., and thence to the Gulf of Carpentaria by the meridian of 138° E. long. Physically Q. may be divided into three large regions, each possessing a distinctive character. The first of these lies between the Pacific Ocean and the Dividing Range which forms a part of the great Australian Cordillera (see AUSTRALIA), and extends to the N. extremity of the continent at Cape York, in 10° 40' S. lat., receiving various names in different parts of its length. The breadth of the tract lying between this chain and the Pacific varies from 30 to 100 miles, but it is evident that it formerly extended as far as the Great Barrier Reef (q. v.) which stretches along the coast for 1200 miles. The coast region is fertile, heavily timbered, watered by numerous rivers, and has

an abundant rainfall. It possesses many good harbours, and is fringed by numerous islands, some of which are of large size. The second region lies immediately to the westward of the dividing range, and consists of table-lands from 1600 to 1900 feet above the sea-level, intersected by two or three ranges which run at right angles to the main chain. It is fairly watered, and possesses a deep, black, and astonishingly fertile soil, composed of decomposed volcanic rocks. In its southern portions this region is lightly timbered, but further N. it consists of rolling downs, which, though treeless, possess the same rich soil, and are clothed with magnificent natural pasture. The Darling Downs (q. v.), Peak Downs, and other rich tracts, are included in this region. The third principal division of Q. lies to the W. of the table-lands, and consists of low, flat, treeless prairies, covering an area of 200,000 square miles, and belonging to the Cretaceous system common throughout the interior of Australia. Recent explorations have shown that much less of this immense territory is desert than was formerly supposed. It is covered for the most part with grasses and salaceous shrubs, on which stock readily fatten, but it labours under the disadvantage of being very remote from a shipping port. At present the wool grown in this region is conveyed in drays to the upper waters of the river Darling (q. v.), and thence by steamer and railway to Melbourne, a distance of 1000 miles.

In common with the rest of Australia, Q. suffers from the want of a range of mountains rising above the snow-line. The dividing range varies in mean height from 2000 feet in its passes to 4500 feet in its peaks, the highest of the latter being the inaccessible Mount Lindsay (5700 feet) on the southern frontier, and the Beilenden Kerr Mountain (5400 feet) on the coast, in 17° S. lat. Nevertheless a number of the rivers of Q. are of considerable size, and several of them are navigable for 40 or 50 miles inland. Of the rivers debouching into the Pacific, the principal, from N. to S., are the Kennedy, Pioneer, Burdekin, Fitzroy (q. v.), Burnett, Mary, and the five which fall into Moreton Bay (q. v.). The chief rivers flowing into the Gulf of Carpentaria are the Mitchell, Gilbert, Norman, Flinders, and Albert. The courses of the eastern and north-western rivers are bordered by belts of the richest alluvial soil, but they are unfortunately liable to periodical inundations. Q. is destitute of lakes, but during part of the year large tracts of the level western country are covered with water.

The climate of so extensive a country as Q. necessarily varies much in dependence upon latitude and elevation. Two-thirds of the colony lie within the tropics, but the heat is greatly mitigated by the dryness and purity of the atmosphere, and Europeans are capable of much greater exertion there than in any other tropical region at the same height above the sea-level. Outside of the tropic the climate is remarkably salubrious, and the mean annual temperature of Brisbane, the capital, is almost identical with that of Funchal in Madeira. On the table-lands the climate resembles that of Southern Europe. Snow scarcely ever falls in Q., even on the mountains. Severe droughts recur at intervals of about seven years, one of the most serious being that of the summer of 1877-78. The rainfall steadily decreases to the westward of the dividing range.

The flora of Q., in those districts which are well watered, is very rich, and the forests contain a great variety of fine timber trees, among which, in addition to the various kinds of Eucalyptus (q. v.), Casuarina (q. v.), wattle, &c., common to the Australian colonies generally, the most distinctive are the giant fig (*Macrophylla*), Moreton Bay Pine (q. v.), cedar, cypress, bloodwood, &c. The tropical rivers are lined by thickets of mangroves, and their bosoms adorned with the pale-blue flowers and immense floating leaves of the *Nymphaea gigantea*, which has been pronounced to be 'the loveliest water-plant in the world.' Tropical fruits of every kind grow to perfection, and on the table-lands British fruits and vegetables are successfully reared. Cotton is indigenous, and, owing to its exemption from frost, is perennial, while in quality it is equal to the finest Sea Island. Sugar-growing has been carried on with entire success since 1867, and at the beginning of 1876 the number of acres under the sugar-cane was 13,460. The principal sugar plantations are on the banks of the eastern rivers between the parallels of 18° and 21°. Arrowroot, coffee, tobacco, maize, &c., are also cultivated. Wheat is grown chiefly on the high grounds, and is of good quality; but the area under this crop is small as compared with that of the southern colonies. This

remark applies, indeed, to agriculture as a whole in Q., in which the total area under crops of all kinds in March, 1877, was only 85,569 acres. This is due principally to the scarcity of labour suited to the climate, in spite of the importation of Polynesian natives to work on the sugar plantations. In January, 1877, there were 9500 Polynesians in the colony. Their interests are protected by Acts of the Imperial Legislature, passed in 1868 and 1874.

The native fauna of Q. resembles that of the rest of Australia, and almost all the mammals are marsupials. Owing to the decrease of the aboriginal inhabitants, the kangaroos of late years increased to such an extent that in 1877 it was found necessary to legislate with a view to a diminution of their numbers. The birds inhabiting the forest regions are numerous, and many of them beautiful. Venomous snakes are also common in the forests, while the tropical rivers are infested by a species of alligator, which attains a length of 25 feet. Q. being eminently a pastoral country, great numbers of sheep and cattle are reared on its vast grazing grounds. The wool of the former is lighter than in the S., but does not deteriorate in quality. In 1876 the total number of sheep in the colony was 7,241,810, and of cattle, 1,985,807.

The mineral resources of Q., though only beginning to be systematically developed, are known to be very great. Gold was discovered at Gympie (q. v.) in 1867, and has since been found in many other places, especially at Cooktown and on the Palmer river in the N. of the colony. The export of gold from Q. now exceeds £1,000,000 annually. Rich deposits of copper ore have also been wrought since 1865, especially in the Peak Downs, at Mount Perry, and Cloncurry. In 1877, however, copper-mining in Q. was almost suspended, and the Peak Downs mine, which in 1865-72 yielded more than £1,000,000 worth of smelted copper, and paid £200,000 in dividends, was sold for £3000. Tin has been remuneratively worked, principally in the southern districts, since 1872, and the annual export averages 5000 tons. The carboniferous beds of Q. are estimated to cover an area of 23,000 sq. miles, but as yet they are little worked. Iron and antimony are also found within the colony, together with fine opals, and diamonds, sapphires, and rubies of small size.

The total value of the imports of Q. in 1877 was £3,672,889, and of the exports £4,102,068. The revenue during the financial year 1876-77 was £1,557,000, and the expenditure £1,472,000. In 1877 there were 272 miles of railway opened for traffic, 200 miles under construction, and 232 miles authorised by the Colonial Parliament. In the same year there were 5041 miles of telegraph in operation. At the census taken in May, 1876, the pop. was 173,180, of whom nearly three-fourths were males. Besides the Polynesians above mentioned, there are (1878) in Q. about 30,000 Chinese who have been attracted by the richness of the Palmer River gold-diggings. 6655 arrived during 1877 alone, and to check this unwelcome immigration a special taxation of the Chinese was resorted to in 1878. The aboriginal inhabitants of Q. are a finer race than those living in New South Wales and Victoria, but their numbers are insignificant, being estimated at only 13,000 in 1871, and having decreased much since then. The principal towns of Q. are Brisbane, Cooktown, Rockhampton, Ipswich, Maryborough, and Townsville, most of which are described under their respective names.

The territory now known as Q. was discovered by Cook in 1770, and was first settled by convicts, who were stationed in or near Brisbane from 1825 to 1839. In 1842 the country was thrown open to free settlers, and in 1859 it was separated from New South Wales, and formed into a distinct colony, its name being changed from Moreton Bay to Q. The sovereign is represented by a Governor, who is appointed by the Crown and assisted by an Executive Council of seven members, who are responsible to a Parliament composed of two Houses, the Legislative Council and Legislative Assembly. The former consists of 21 members, nominated by the Crown for life, and the latter of 32 members, representing 22 constituencies, and elected for five years. See *My Wife and I in Q.*, by C. H. Eden (Lond. 1872); *Report of the Q. Commission to the Philadelphia International Exhibition* (Lond. 1877); *The Australian Handbook for 1877* (Lond. 1878); *Q. the Progressive, By a Forty Years' Colonist* (Lond. 1877); *Q. Almanac* (Brisb. 1878).

Queen's Metal, an alloy of tin intermediate in hardness between Pewter (q. v.) and Britannia Metal (q. v.). It is com-

posed of 9 parts tin and 1 each of antimony, lead, and bismuth, and is used for common spoons, teapots, and like articles.

Queen's Regulations, the instructions issued to the army through the commander-in-chief, and to the navy through the Admiralty, regulating the internal economy and discipline of the services. They interpret and temper for the time being the Mutiny Act and the Articles of War. Corrections and additions are frequently made to the Q. R. Every officer requires to possess a copy of them, and to be thoroughly acquainted with its contents. Financial affairs come under the scope of the Q. R. for the army, but not for the navy.

Queens'town, a seaport of Ireland, county Cork, 14 miles S.E. of Cork, was formerly called Cove of Cork, but received its present name on the occasion of Queen Victoria's visit in 1850. Previously to 1786 it was only a fishing village, but was made an admiral's station during the French war, and owing to its fine harbour rapidly rose in importance. 600 merchant vessels have been at anchor in the harbour at one time. Q. is built in parallel streets around a natural amphitheatre, and is noted for its equable and mild climate, which makes it a favourite resort for invalids. The finest building is the Roman Catholic Cathedral. Q. carries on little trade of its own, but is much used as a port of call. Pop. (1871) 10,340.

Queen's Yellow or Turbith's Mineral, a pigment consisting of a subsulphate of mercury. It is employed only as an artist's colour.

Quentin, St., a town of France, department of Aisne, on the Somme and the Canal of St. Q., which connects the Somme and Scheldt, 80 miles N.E. of Paris by rail. It is well built, has a fine townhouse and noble Gothic church, besides a lyceum, museum, theatre, and library of 15,000 vols. Q. is a great seat of the cotton and woollen manufacture, being the centre of a district employing in 800 factories 130,000 persons, and producing annually wares to the value of £3,500,000. Pop. (1872) 33,995. At St. Q., August 10, 1557, the French under Montmorency were defeated by the Spaniards under Duke Philibert of Savoy.

Quercitron is the trade name of *Quercus tinctoria*, a N. American species of oak, forming a fine forest-tree in the eastern United States, where its timber from its strength and durability is much esteemed for shipbuilding, and its bark is used for tanning leather and dyeing yellow. For dyeing purposes, the crushed inner bark is exported in considerable quantity to Europe.

Quereta'ro, capital of a state of the same name in Mexico, is situated 6364 feet above the sea, on the great road from Mexico to San-Luis Potosi, 110 miles W.N.W. of the former. It is a regularly built town, is surrounded with gardens, and has three large squares, many fine fountains and buildings, several churches, and eleven convents, the finest of which is that of Santa-Clara. It has several good schools, an hospital and lunatic asylum, and is supplied with water by an aqueduct (*cañeria*) 150 years old. Q. is the chief seat of the cotton manufacture in Mexico, but woollens and leather are also produced. Pop. 47,570. At Q. the Emperor Maximilian (q. v.) was shot, May 15, 1867, on the capture of the town by the Republicans.

Quern (Old Eng. *cwætern*), a handmill used for grinding corn, and which in one shape or other is one of the most ancient and most widely used of implements. The ordinary Q. consists of two round stones, the lower and heavier of which may measure about 2 feet in diameter. Within a deep depression in the nether stone the upper and lighter stone is fitted so as to rotate easily when moved by a vertical handle placed towards its outer circumference. Through the centre of the upper stone is a round hole, and in using the Q. the corn to be ground is placed into the hole with one hand while the other rotates the stone. The corn by centrifugal force passes outward between the two stones, being crushed and ground as it moves out, and there is generally a small orifice in the side of the under stone by which the ground meal escapes. In certain kinds of Q. found in tropical Africa and India, the upper stone is rubbed with an oscillating motion in the cavity of the under stone. Thus the former is the prototype of the stones of the flour-mill,

while the latter is analogous to the arrangement of mortar and pestle. The Q. is frequently referred to in Scripture under the name of millstones, and in Wickliff's translation of the New Testament the word itself occurs, 'Two wymmen schullen be gryndyng in oo queerne.' Till comparatively recent times the Q. was used in the W. Highlands of Scotland, and it is still used in the W. of Ireland.

Quesaltenango, capital of the province of Q., and the second city of Guatemala, in Central America, on the river Samala, 44 miles from the Pacific coast, and 65 miles W.N.W. of New Guatemala. It was founded by Alvarado in 1524 on the site of the ancient Felahuh, and is a well-built town. Q. manufactures cottons and woollens. Pop. 25,000, mostly Indians.

Quesnay, François, a French political economist, is said (*Mémoires* of the Academy of Sciences for 1774) to have been the son of an advocate, and to have been born at Mérey, near Versailles, June 4th, 1694. All other authorities describe him as the son of a peasant, and he was probably born at the village of Ecquivilly, in the Isle of France. At Paris he studied metaphysics and medicine—even painting and engraving—and in 1718 established himself as a surgeon at Mantes. Here he soon made himself known as a man of talent. In 1727 he refuted a work on blood-letting by Silva, who then reigned omnipotent in medicine at Paris; and this courageous performance gaining the attention of Peyronnie, the king's chief surgeon, Q. was appointed secretary to the new Academy of Surgery (1737). Six years after his appointment he produced the first volume of that Academy's *Mémoires*, with an elaborate preface; and for seven years he defended the interests of his society in its celebrated quarrel with the Faculty of Medicine. In 1745 he became consulting physician to Louis XV. Whatever his skill in medicine, he proved a witty companion to royalty, and Louis dubbed him *son penseur*. At the Court of Versailles he lived under the protection of Madame de Pompadour, and enjoyed ample leisure for study. He had already published two works in 1736—*L'Art de guérir par le saignée* and *Essai Physique sur l'Economie Animale*; these were enlarged in 1747. In 1748 he brought out an *Examen Impartial des Contestations des Médecins et des Chirurgiens de Paris*; in 1749, *Traité de la Suppuration*, *Traité de la Gangrene*, *Mémoire sur la Sagesse de l'Ancienne Législation de la Chirurgie en France*; in 1753, *Traité des Fièvres Continues*. These are all the medical works certainly known as Q.'s. In 1756 he entered the field of Economics by contributing to the *Encyclopédie* the articles *Fermier* and *Grains*; and in 1758 appeared a work of his, now lost, the *Tableau Economique*. This book, printed by command of the king (Laharpe called it the 'Alcoran of Economists') had for epigraph the following remarkable sentence:—'Pauvres paysans, pauvre royaume; pauvre royaume, pauvre toi.' All Q.'s writings on Political Economy were gathered together by Dupont in 1767, under the title of *Physiocratie*. For Q.'s system of Economics, which founded wealth entirely on agriculture, see **POLITICAL ECONOMY**. He was head of the Economists, a set of men who did France great service in advancing free-trade and exposing the errors of the mercantile system, but who eventually drifted from economics into politics, and gave the world many fine, impossible schemes of government, such as the elder Mirabeau's. To Q., more than to any other, Adam Smith was indebted for guidance in drawing up his great treatise. Q. died at Versailles, 16th December 1774. He was a philosopher and a wit; and above all, in the corrupt Court of Louis—under the very roof of Pompadour—he lived a life of spotless virtue and unobtrusive charity. The best edition of Q.'s works, with life, forms the 11th volume of Guillaumin's *Collection des Principaux Economistes* (Par. 1846).

Quesnel, Pasquier, a French theologian, was born at Paris, July 14, 1634. After studying at the Sorbonne with great distinction, he attached himself to the Oratory, became priest in 1659, and in 1662 was appointed principal director of the Paris house. His first work was *Réflexions Morales sur le Nouveau Testament*; and in 1675 he published *Ouvrages du Pape Saint-Leon*, founded on an old Venetian MS. which had belonged to Cardinal Grimani. Q. having embraced the doctrine of Jansen, was driven from his post by the Archbishop of Paris (who acted upon a bull of Alexander VII.), and in 1681 retired

to Orleans, but was soon after forced to take refuge in Brussels. At Brussels he associated with Arnauld, under whose direction he wrote a series of *Reflexions Morales* on the Acts and Epistles (1693-94), which excited the bitterest animosity of the Jesuits. At Arnauld's death he headed the Jansenists, and in Brussels, 1703, he was arrested by order of Philip V. of Spain. Escaping from prison, he fled to Holland, and there continued his work of encouraging his persecuted friends. In 1713 his *Reflexions* were condemned by the Unigenitus Bull. Q. formed a Jansenist community at Amsterdam, and died there 2d December 1719. The enumeration of Q.'s books occupies two pages of Moreri. The principal are:—*Tradition de l'Eglise Romaine sur la Prédestination* (Köln, 1687); *L'Idée du Sacerdote et du Sacrifice de Jésus Christ* (Par. 1688); *La Discipline de l'Eglise, tirée du Nouveau Testament* (Lyons, 1689); *Prédictions Chrétiennes* (1695); *Causa Arnaldina, seu Arnaldus a Calumniis vindicatus* (1697); *La Paix de Clément IX.* (1701). Several of Q.'s works have been translated into English, e.g.:—*Q.'s Reflections on St. Matthew's Gospel*; *Q.'s Reflections on the New Testament*; *Devotional Commentary on the Gospel of St. Matthew* (1869). See the various histories of Port Royal (q. v.), and Guettée's *Histoire de l'Eglise de France* (vols. x. and xi.).

Quetelet, Lambert Adolphe Jacques, was born at Ghent, February 22, 1796. He was educated at the lyceum of Ghent, and there became professor of mathematics in 1814. In 1819 he was appointed to the chair of mathematics in the Athenæum at Brussels. Sent by William I. to Paris to finish his astronomical studies, he was recalled in 1826 to direct the building of the Royal Observatory, and in 1836 was nominated professor of astronomy at the Ecole Militaire. Elected a member of the Royal Academy in 1820, he became its secretary in 1834. Q. died at Brussels, 17th Feb. 1874. His chief works are:—*Correspondance Mathématique et Physique* (Brussels, 11 vols. 1825-39); *Astronomie Élémentaire* (Par. 1826), 4th edition, under title of *Éléments d'Astronomie* (Brussels, 2 vols. 1848); *Recherches sur la Population, les Frisons, &c., dans le Royaume des Pays Bas* (1827); *Résumé d'un Cours de Physique Générale* (3 vols. 1827-34); *Recherches sur la Reproduction et la Mortalité, et sur la Population de la Belgique* (1832); *Statistique Criminelle de la Belgique* (1832); *Mémoire sur les Variations Diurnes et Annuelles de la Température, et en Particulier de la Température à Diverses Profondeurs, d'après les Observations faites à l'Observatoire de Bruxelles* (1834); *Annuaire de l'Observatoire Royal* (1833-62), completed by the *Almanach Séculaire* (1854); *Sur l'Homme* (Par. 1835); *Annales de l'Observatoire Royal* (14 vols. 1843-59); *Lettres au Duc de Saxe-Gotha, sur la Théorie des Probabilités appliquée aux Sciences Morales et Politiques* (1846); *Du Système Social* (Par. 1848); *Théorie des Probabilités* (1853); *Académie Royale de Belgique* (1855); *Histoire des Sciences Mathématiques et Physiques chez les Belges* (1865); *Les Sciences Mathématiques et Physiques chez les Belges au Commencement du XIX. Siècle* (1866); *Météorologie de la Belgique* (1867).

Quett'a or Shawl ('fort'), a small fortified town in the independent state of Kelat, in Beluchistan, on the Scinde frontier of British India, 5600 feet above the sea. It stands in a little valley of the same name, and has great political importance as commanding the Bolan Pass, between Scinde and Central Asia. It was occupied for three years during the Afghan war by a British force, who used this route to reach Candahar. Part of the escort of the British political agent was stationed here during the winter of 1876; and in accordance with the treaty of 1877 it has been permanently occupied by a British garrison. A road has been constructed, and a telegraph laid. See also **KELAT**.

Queue (Fr. 'a tail'), the tie of a wig. See **PERIWIG**.

Quevedo y Villegas, Francisco Gomez de, was born September 26, 1580, at Madrid, where his father was an officer at the court of Philip II. He graduated a doctor of theology in the University of Alcalá as a boy of fourteen, and before he was of age had mastered six languages, four sciences, and canon and civil law, paying, however, for his assiduity by bleared eyesight and a deformed gait. At Madrid he killed his man in a duel in behalf of an unknown lady, and flying to Sicily, found a protector in the Duke of Ossuna. By him he was employed in various affairs of state; amongst others, on two missions to the Spanish court (1615-17), where not only was he pardoned for

his late offence, but received a pension of 400 ducats and the Order of Santiago. On his patron's translation to the viceroyalty of Naples Q. became his Minister of Finance, but on that patron's fall in 1620 he was banished for three and a half years to his ancestral estate of Torre de Juan Abad. Thenceforward, refusing all offers of preferment, he devoted himself to letters, till in 1639 a satire on the government, falsely imputed to his pen, brought him four years' imprisonment in a loathsome dungeon of the convent of San Marcos de Leon. Two years after his release he died at Villanueva de los Infantes, September 8, 1645. Few writers are more deservedly famous, few more undeservedly unread, than Q. His works were as multifarious as his attainments, an *olla podrida* of religion and comedy, filling eight stout volumes of prose and three of poetry, with a still larger quantity of unpublished matter. His poetry includes imitations of Anacreon, satires after Juvenal, parodies of Gongora and the Marinists, a sonnet on the Immaculate Conception, and probably a small volume of dainty odes, elegies, and eclogues, published by him in 1631 as by the 15th c. 'Bachiller Francisco de la Torre.' Amongst his prose writings are treatises on Providence and the immortality of the soul, translations of Epictetus and Seneca, and, finest of all, the satires *Vida de gran Tacaflo* (1627), the six *Suenos* (1633), *Cartas del Cavallero de la Tenaza* (1635), &c., where every class of society comes in for its special gibe—the doctor sits in Hell with the murderer, the fires of Purgatory boil the priest's pot, and notaries fly from the sound of their own lies, those only escaping who have lost their ears in the pillory. The best edition of Q.'s works is that by Guerra y Orbe (Mad. 1852). Of the English perversions of his satires by I. Strange, Stevens, and others, it is enough to state that they all come through the French, and have lost most of their native wit and gained much foreign dullness on the way. See Ticknor's *History of Spanish Literature* (vol. ii. p. 237), and an admirable essay by James Mew in the *Gentleman's Magazine* for January 1878.

Quíberon, a peninsula, with a small fishing village of the same name, stretching southward from the coast of the department of Morbihan, France. Here, in June 1795, Puisaye, the leader of the Chouan royalist rebels, attempted, with the assistance of a British fleet under Admiral Warren, to effect a landing. His force was, however, driven into the sea by the troops of the Convention under General Hoche. Many were drowned, some were saved by the British ships, and about a thousand, who surrendered, were summarily shot. Admiral Hawke defeated a French fleet under Admiral Conflans in Q. Bay, in 1759.

Quichua, an Indian race inhabiting Peru, as well as parts of Ecuador, Bolivia, and the Argentine Republic. With the Aymará the Q. Indians formed the bulk of the population of the ancient empire of the Incas, in which the Q. language was predominant. Cuzco (q. v.), the Inca capital, continues to be the centre of Q. influence. At the present day the Q. language, which contains twenty-six consonants and eight vowels, is spoken by a million and a half of people in Peru, and by half a million more in Bolivia, &c. The word Q. signifies 'temperate climate,' as opposed to *puna*, or 'cold climate,' and derives its origin from its being in the first instance used to designate the inhabitants of the temperate portions of Peru, as distinguished from those of the punas, or cold table-lands. See **PUNA**.

Quickens (Old Eng. *cwic*, 'alive'), see **COUCH-GRASS**. Quicken or Quick-beam, or Wicken, are also names of the Rowan (q. v.).

Quicklime, pure oxide of calcium, is prepared by driving off by heat carbonic anhydride from marble, common limestone, or other carbonate of lime. It is a white caustic powder, which combines energetically with water to form *slaked lime*. Q. has many important uses, the chief of which are as an ingredient of mortars and as manure.

Quick Match, a combustible material used in pyrotechny. It is prepared by soaking cotton strands in a thin paste of gum-water and fine gunpowder; the cotton is then wound on a frame and sifted over with fine meal powder, after which it is set aside to dry.

Quick'silver. See **MERCURY**.

Quietism is a phase of Mysticism (q. v.), which, like the more general phenomenon, has manifested itself in connection

with almost every system of philosophy and religion by an excess or perversion of contemplation. The Quietists are those who resign themselves in a state of perfect mental inactivity, without thought, hope, or wish, to receive a divine manifestation, in order to bring the soul into direct and immediate union with the very nature of the Godhead. Q. made its appearance in the Christian Church in the 17th c., the leader in the movement being Molinos (q. v.), a Spanish Jesuit. Other eminent Quietists were Madame Guyon (q. v.) and Archbishop Fenelon (q. v.). A notable controversy on the subject took place between the latter and Bossuet (q. v.). See Molinos' *Spiritual Guide* (1688); *Life of Lady Guyon* (Bristol, 1772); Vaughan's *Hours with the Mystics* (2 vols. 1856; 2d ed. 1860).

Quilima'ne, or **Quill'imaïne**, a Portuguese settlement in Mozambique (q. v.), 15 miles from the mouth of the Q. River, which during a fourth part of the year communicates with the Zambezi. Q. was founded in 1764, is the chief town of the military district of Zambezia, and in spite of a dangerous bar at the mouth of the river on which it stands, has a tolerable trade. Built in a mangrove swamp, it has the reputation of being the most unhealthy of all the Mozambique ports. Pop. about 15,000. The imports in 1875 amounted to £22,311, the exports to £21,780.

Quilla'ja is a small genus of S. American colossal evergreen trees, belonging to the wing-seeded section of *Rosaceæ*, and remarkable for possessing saponaceous qualities. The bark of *Q. saponaria*, called quillai or soap-bark, is often used in Chili for washing purposes as a substitute for soap. The European import is the chief ingredient in washes for promoting the growth of hair. *Q. Selloviana* is similarly utilised in Brazil.

Quillo'ta, a town in Chili, capital of a department of the same name. It is situated on the Aconcagua river and Valparaiso and Santiago railway, 20 miles from the former town. Rich copper mines are worked in the vicinity. At the census of 1875 the pop. of the town was 11,347; of the department, 45,211.

Quills. The quill of a feather is that portion of the shaft which is hollow, round, and translucent. Q. have several applications in the arts, and before the introduction of steel pens they constituted almost the only pens for ordinary writing. They are still in extensive demand for writing, in addition to which they form holders or tubes for artists' brushes, toothpicks, &c. Q. for writing are principally plucked from the wings of the goose, the five outer feathers of each wing being alone of use for this purpose. Swan Q. are also employed, and are in quality much preferable to goose Q., but owing to the comparative rarity of the bird they are scarce and very highly prized. Crow Q. are used to a limited extent for fine lines and drawings, and Q. from the turkey, the eagle, and other birds are occasionally seen. Q. for writing are cleaned and tempered by plunging them into hot sand, drawing them while soft under the edge of a blunt knife, and subsequently polishing with a cloth. Goose Q. are largely obtained from the Baltic provinces of Russia, where geese are kept for the sake of their feathers; and these, together with Q. from Holland, Poland, and the German Empire, are severally recognised as varieties in commerce.

Quilon, or **Coulân**, a considerable town in the native state of Travancore, S. India, on the sea-coast, 38 miles N.W. of Trivandrum, and 740 miles S. E. of Bombay. It had some historical importance in the early days of European settlements on the Malabar coast, and a small detachment of British troops is still stationed here.

Quil'tor, a term applied by veterinarians to an unhealthy or sluggish wound at the upper part of the foot of the horse. It may be caused by violence, or may arise from neglected abrasions, corns, &c. *Poulticing* is recommended as a means of cleansing the suppurating surface, and *astringent lotions* may afterwards be used to stimulate the formation of healthy granulations.

Quimper, chief town of the department of Finistère, France, at the confluence of the Odet and Benaudet, 34 miles S.E. of Brest by rail. The old part of the town is built in an amphitheatre with walls and towers; the new lies at the foot of rocks 656 feet high. The Gothic cathedral, commenced in 1424, is

the finest building. Q. has trade in corn, flour, fish, and cattle, and considerable brewing, tanning, and pottery, besides sardine-fishing. Pop. (1872) 13,159.

Quin, James, a celebrated English actor, of Irish extraction, was born in London 24th Feb. 1693. He first appeared at Dublin in 1714, after which he gradually won a reputation at Drury Lane and the Lincoln's-Inn-Fields Theatre. He achieved a great success in 1720 as Falstaff, a character in which he is said never to have been surpassed, and for the next twenty years—till the appearance of Garrick—he reigned without a rival on the English stage. Cato and Captain Macheath were two of his best impersonations. He played at Covent Garden from 1732 to 1740. Q. instructed the children of Frederick, Prince of Wales, including George III., in elocution. After his retirement from the stage in 1751 he made occasional gratuitous reappearances in the part of Falstaff till 1754, when his voice failed. He spent the last years of his life at Bath, and died January 21, 1766. Q. had an imposing figure, an expressive face, and a good voice. He was fond of the table, was a capital story-teller, and had a fund of pointed if coarse wit. His fiery temper led to two or three duels, in one of which he unfortunately killed his opponent. Otherwise his character was manly and not devoid of generosity. A compilation entitled *Q.'s Fests, or the Facetious Man's Companion*, appeared shortly after his death, but its authenticity is doubtful.

Quince (*Pyrus Cydonia*) is a hardy deciduous tree, with the extremities of the branches, the under side of the ovate leaves, the inflorescence and calyx, all coated with a white tomentum; the blossoms are large, pale-pink, and white; the fruit is pear-shaped, and the seeds are covered with a mucilaginous pulp. It is apparently wild in N. Persia westward to Greece; or perhaps to Italy, as Pliny states that some varieties of it in his time were growing wild in the hedgerows. The fruit, which on approaching maturity assumes a fine golden colour, has a powerful odour. The flavour is austere, so that it is unfit for eating raw, but is much esteemed stewed with sugar, or along with apples and pears in tarts; and in confectionery it forms an excellent marmalade and syrup—especially the Portugal variety. A wine is also made from it. The seeds are used for bandoline and as an emollient application to the skin. The tree itself is worthy of growth for its ornamental appearance both in flower and fruit, and the stock is much used in grafting for dwarfing the pear. *P. Sinensis*, the Chinese Q., yields an inferior fruit to the above. *P. Japonica*, sometimes called the Japanese Q., is a common ornamental garden shrub, producing in spring an abundance of glowing-red flowers.

Quincy, a town of the State of Illinois, U.S., on the Mississippi, 160 miles above St. Louis, and 263 miles S.W. of Chicago. Q. is the point of junction of eight railroads, has thirty churches, ten newspapers, a medical college, a Methodist seminary, and many other public institutions. The first Protestant bishop of Q. was consecrated May 15, 1878. Its manufactories employ 3500 operatives, and produce annually \$10,000,000 worth of goods. Pop. (1876) 37,000.

Quincy, Josiah, LL.D., a distinguished American lawyer and politician, born in Boston, Massachusetts, February 4, 1772. He was descended from a notable New England family, originating with Edmund Q., who went on an official mission to England in 1737. Q.'s father, also called Josiah Q., was a Revolutionary patriot, but died before the Revolution was accomplished, in 1775. Q. graduated at Harvard in 1790, and was admitted to the bar in 1793. He was member of the State Senate in 1804, and member of Congress from 1805 to 1813, when he strenuously opposed the war with Great Britain. He was among the first to attack the principle of slavery, and on the triumph of the Democrats about 1836 retired from Congress and devoted himself to local politics and to scientific agriculture. From 1823 to 1829 he was Mayor of Boston, and from 1829 to 1845 he was president of Harvard University. He lived to denounce the secession of the Southern States in 1860, and died at Quincy, Massachusetts, when the Civil War was at its height, 1st July 1864. His principal works are a *Memoir* of his father (1825); a *History of Harvard University* (1840); *Municipal History of Boston* (1852); *Life of John Q. Adams* (1858).—His second son, **Edmund Q.**, born 1808, an active Abolitionist, published his *Life* (1867), and edited his *Speeches* (1875).

Quinet, Edgar, was born at Bourg, in Bresse, February 17, 1803. After finishing his schooling at Lyon, he went to Paris in 1820, studied law, and for a time entered the employment of a banker. In 1823 he produced a satire called *Les Tablettes du Juif-Errant*. Having spent some time at Heidelberg, on his return he published the *Idées sur la Philosophie de l'Histoire de l'Humanité* (3 vols. 1826-27), a translation of Herder's well-known history, with an introduction of which both Goethe and Cousin spoke with admiration. He then took part in a scientific commission to the Morea, and published the results of his observations under the title of *De la Grèce Moderne et de ses Rapports avec l'Antiquité* (1830). His pen was next engaged in the service of the *Revue des Deux Mondes*, in the pages of which appeared his mystical prose-poem, *Ahasuerus*, afterwards published in book form (1833). On the death of his father, he made a tour through Italy and Germany, in the latter country marrying the daughter of a Protestant pastor. In 1835 appeared his poem *Napoleon*, and in 1838 his *Prométhée*, between which he published a *Histoire de la Poésie Epique* and an *Examen de la Vie de Jésus de Strauss*. From 1838 to 1842 Q. held the post of professor of foreign literature at Lyon, and delivered lectures on the history of civilisation, which took shape afterwards as *Le Génie des Religions* (1843). Then his republican tendencies broke out in the *Avertissement au Pays* (1841), which demanded, among other reforms, the abolition of the treaty of 1815; and although he was in 1841 appointed to the chair of the Literature of Southern Europe in the College of France, he attacked the Jesuits so fiercely, in company with Michelet, that he was suspended from his duties as professor. He then travelled in the south of Europe, and published *Mes Vacances en Espagne* in 1845-46. After writing a political pamphlet entitled *La France et la Sainte Alliance en Portugal*, Q. was sent to the Legislative Assembly by the department of Ain, and appointed colonel of the 11th legion of Paris. In the Assembly he spoke little, but he upheld his party, the Extreme Left, in pamphlets such as *La Croisade Autrichienne, Française, Napolitaine, Espagnole, contre la République Romaine* (1849); *L'Enseignement du Peuple* (1850); *L'Etat de Siège* (1850), and letters published in *La Presse*, *L'impôt sur le Capital dans la République de Florence* (1850). By decree of January 9, 1852, he was exiled, and fled to Brussels, where he married as his second wife a daughter of the Moldavian poet Assaki. In 1852 appeared his *Révolutions d'Italie* (3 vols.); in 1853, *Les Esclaves*, a companion poem to those already mentioned, the four forming a strange embodiment of political mysticism; in 1854, *L'Histoire de la Fondation de la République des Provinces Unies*; in 1856, a *Lettre à E. Sue sur la Situation Religieuse et Morale de l'Europe* (Brussels); in 1858, *Martin l'Enchanteur*, a poem; in 1862, *La Campagne de 1815*; in 1865, *La Révolution*; in 1867, *La Question Romaine devant l'Histoire*; in 1874, *L'Esprit Nouveau*; in 1875, *Le Livre de l'Exil*. Q. died at Paris, March 27, 1875. The fragments of his unfinished work on ancient Greece were published in 1877 under the title of *Vie et Mort du Génie Grec*. His *Œuvres Complètes* were published in 1858 (11 vols.); and a re-issue of these, with additions, was begun in 1877. See *Revue des Deux Mondes* for July 1858, and Chassin's *E. Q. Sa Vie et Son Œuvre* (Par. 1859).

Quin'ia, or Quinine. The alkaloid Q. was first separated from the other ingredients of the cinchona bark by Pelletier and Caventou in 1820. Q. or its salts, in powder or solution, have little or no influence when applied to the skin, but they have a stimulant or irritant action upon the mucous membranes. Eulenburg found that Q., when applied to a nerve, did not produce contraction of the muscles supplied by it, but that it produced violent contractions when placed upon the muscles themselves; and he concluded that it was a muscle-irritant, but not a nerve-irritant. Q. acts upon the stomach very much as a simple bitter, stimulating digestion and increasing the appetite; but in large doses it may cause nausea and vomiting. Q. is extensively used in the treatment of intermittent fevers and agues, and it is useful in many chronic diseases in which intermissions do not occur, as in chronic catarrh, diarrhoea, scrofulous conditions, general debility, and also in the various forms of neuralgia and acute lumbago. When the system is fully under the influence of Q., the condition is called cinchonism, the first symptoms being ringing in the ears, slight fulness in the head, and deafness. With larger doses these symptoms are intensified, and the sense of distension in the head

may point towards a cerebral congestion; but in complete cinchonism giddiness and staggering in walking are very common. According to Eulenburg, Q., in poisonous doses, abolishes all reflex actions before it affects voluntary motion; in Q. poisoning, no stage of excitement of reflex activity precedes that of the depression of function. In 1867, Professor Binz found that Q. added to human blood in the proportion of one part to four thousand immediately checks, and in a short time arrests, the amoeboid movements of the white-blood-cells; and on account of its power of arresting or preventing putrefactive fermentation, by destroying the entities which produce such changes, he recommended it in the treatment of the so-called *septic diseases*. The great value of Q. as a therapeutic agent consists in its specific action on all forms of disease dependent upon *malarial poisoning*. In the treatment of every form of malarial disease, the administration of Q. should be preceded by an active cathartic, and the dose of Q. may vary from 5 grains three times daily to 10 or 20 grains. When there is great irritability of the stomach, Q. may be given by injection per rectum, or by subcutaneous injection. The pharmaceutical preparations are *Pilula Q.*, dose, 2 to 10 grains; *Tinctura Q.*, dose, 1 to 1½ drms.; *Tinctura Q. Ammoniata*, dose, 1 to 2 drms.; *Vinum Q.*, dose, ½ to 1 oz. The non-official preparations of Q. are the *arsenate*, the *carbolate*, the *citrate*, and the *valerianate*.

Quin'isext (Lat. *quini*, 'by fives,' *sextus*, 'sixth') is the name given to a Church council held at Constantinople in 692, and composed chiefly of Eastern bishops. By the Eastern Church it is counted as the seventh general council, and received the above name because its decrees were considered necessary as supplementary of those of the *fifth* and *sixth*. But as six of its canons were opposed to the opinions and customs of the Western Church, it was not counted among the general councils by that church. From the place of meeting, a hall in the imperial palace called Trullus, it was also called *Concilium Trullanum* or *in Trullo*.

Quinoa, or botanically *Chenopodium Q.*, is a tall annual, producing dense erect compound panicles of dense green flowers. A native of Peru and Chili, it is cultivated there for its seeds, which are used as an article of food, and are very nourishing. They are prepared as a kind of gruel, or are roasted like coffee and then boiled, the liquor forming a broth.

Quinquages'ima (Lat. 'fiftieth,' scil. *dies*), originally meant the fiftieth day after Easter (q. v.), or Pentecost (q. v.). It now means the Sunday before the beginning of Lent (q. v.), which happens to be the fiftieth day before Easter.

Quin'queremes were vessels with five banks of oars, manned, according to Polybius, by 300 seamen and 120 soldiers. Invented by the Salaminians, who made them for Dionysius shortly after 400 B.C., they were adopted by the Greeks after the death of Alexander, and somewhat later by the Carthaginians. From 266 B.C. the Romans kept fleets of Q., their first model being a Carthaginian vessel wrecked on the Bruttian coast in the first Punic War.

Quin'sy. See THROAT, DISEASES OF.

Quint, an organ stop sounding a fifth above the foundation stop, 5½ feet in length on the manuals, and 10½ feet on the pedal.

Quin'tal, a French standard of mass, equivalent to 100 'livres,' and thus corresponding to the English hundredweight. When the metrical system was introduced, the name was retained as equivalent to 100 kilogrammes, giving it about twice its old value.

Quinta'na, Manuel José, a Spanish poet, born at Madrid, 11th April 1772, after studying at Cordova and Salamanca, became an advocate in his native city. In 1791 he produced a poem on the dramatic art, exalting Corneille and Molière at the expense of Lope de Vega and Calderon. His own two tragedies, *El Duque de Visco* (1801), founded on Lewis's *Castle Spectre*, and *Pelayo* (1805), are marred by Gallicisms, and far inferior to his *Oda al Mar* (1795) and fiery *Odas á España libre* (1808), in which, as in his journal, the *Semanario Patriótico*, he roused his countrymen to resist the Napoleonic aggressions. For his services during the War of Liberation he was rewarded by Ferdinand VII., to whom Liberal propaganda was an unpardonable offence, by six years' imprisonment in the fortress of

Pamplona (1814-20). Riego's insurrection released him, broken in spirit, to accept offices from his ungrateful master, whose praises he celebrated in a feeble ode (1828), and to become the tutor of Isabella, Spain's future queen (1840-43). Having held the direction of public instruction (1835-51), and been honoured with a public ovation (1855), he died at Madrid, 11th March 1857. In June 1877 his remains were removed to the National Pantheon. Besides his poems, Q. published *Vidas de los Españoles celebres* (3 vols. Mad. 1807-34), and edited *Poesías Selectas Castellanas* (3 vols. Mad. 1808; enlarged, 1830 and 1833). The best edition of his works is in the 19th vol. of the *Biblioteca de Autores Españoles* (Mad. 1852). See vol. iii. p. 285 of Ticknor's *History of Spanish Literature* (Lond. 1849).

Quintessence, literally the fifth essence, was the name given by the ancient philosophers to a substance higher and more subtle than the four recognised elements, fire, air, water, and earth. The alchemists used the words with a very similar meaning; but it is now employed in a purely figurative sense.

Quintet, a musical composition in five parts, for five voices or instruments. Instrumental (string) quintets are written in symphony form, and may be composed for two violins, two violas, and violoncello; two violins, a viola, and two violoncellos; or two violins, a viola, a violoncello, and a double bass.

Quintilianus, M. Fabius, the greatest of Roman rhetoricians, was a native of Calagurris (*Calahorra*) in Spain, in the upper valley of the Iberus (*Ebro*). His period extends from 35 A.D. to 95 A.D. (*Zeuffel*). Whether he was reared in Rome or not is uncertain. He must at least have completed his education there. In his youth he attended the lectures of Domitius Afer, and, if not a pupil of his, was an eye-witness of the decline of his powers. Domitius Afer died 59 A.D. (*Tac. Ann. xiv. 19*). In 68 A.D., Q. commenced practice at the Roman bar. There his appearances secured for him a distinguished success. His forte, however, lay in his ability to teach rhetoric. In eloquence he had no rival. Pliny and the grand-nephews of Domitian were his pupils. From the Emperor (Domitian) he received the investiture and title of consul (*Consularia ornamenta*), and under an endowment by Vespasian he enjoyed a salary from the imperial treasury. That he devoted a long series of years to public teaching is evident; that he retired into private life is acknowledged; but that he lived to 118 A.D., as dictionaries generally state, is by no means certain. The pecuniary circumstances of the family, and more especially of Q., have afforded matter for considerable dispute. Juvenal considers him a child of good fortune (see *Sat. vii. 186 sq.*). Pliny, on the other side, distinctly states that he could but give a poor—it might be for him liberal—outfit to his daughter: 'te porro animo beatissimum, modicum facultatibus, scio.' We, of course, assume that the Q. of Pliny is the rhetorician.

The great work of Q. is entitled *De Institutione Oratoria, Libri XII*. It is dedicated to his friend Marcellus Victorius, himself an orator (*cf. Statius, Silv. iv. 4*), and was written during Domitian's reign, while the author held a tutorship in the imperial family. It is characterised alike by luminous insight and precision of criticism, and has laid down the canons of literary taste for the whole civilised world. Besides the *Institutions*, 164 *Declamations*, 19 of which are extant in full, the rest fragmentary, are ascribed to Q., but these are now generally held to be spurious. Internal evidence shows them to belong to different periods. The first MS. of Q. was discovered in the monastery of St. Gall by Poggio of Florence. The *editio princeps* of the *Institutions* was first printed at Rome (fol. 1470). Next followed the Venetian edition, 1471, and the Aldine (Ven.) 1514. The favourite editions of Q. are those of Burmann (2 vols. 4to. Leyden, 1720), and of Spalding and Zumpt (6 vols. 8vo. Leips. 1798-1829). The most useful editions are those of E. Bonnell (Leips. Teubner, 1854), and of C. Halm (Leips. Teubner, 1868). On the criticism and elucidation of the text of Q. the student may with advantage consult the *Quæstiones Quintilianæ* of F. Müller (Halle, 1840), the works of F. Bahlmann (Berl. 1859), F. Meister (Liegnitz, 1860), J. Stander (Bonn, 1865), and above all the German version of Bossler and Baur (Stuttgart, Metzler, 1863). Translations in English, French, and Italian are numerous.

Quintin (Fr. *quintaine*), an ancient sport practised by those tilting on horseback with the lance. An upright post was erected, having a cross-piece on the top, turning on a pivot, with a board fixed at one end, and a sand-bag hanging from the

other. The play was to strike the board with the lance, and at the same time ride past at such speed as to escape a blow from the sand-bag as it swung round.

Quintuplet, having together the value of five notes of the same kind.  It is seldom used in modern composition.

Quirinus literally means lance-bearer, from *quiris* or *curis*, 'lance,' and *ire*, 'to go.' Hence Mars and Janus are primarily characterised as divinities that hurl the spear. Specially under this name the deified Romulus (q. v.) was worshipped, and the festival in his honour was called *Quirinalia*. One of the seven hills of Rome (q. v.) bore the name *Collis Quirinalis*. It lay N. of the Palatine, and was one of the oldest quarters of the city. Here were the gardens of Sallust, the baths of Diocletian, the Pretorian camp, two circuses, and many temples.

Qui Tam, in English law, is the term denoting an action under a penal statute for the sake of the penalty. Generally, no procedure for recovery of a penalty or forfeiture under the stamp-laws can be instituted against any one, except with the concurrence of the Attorney-General in England, or with that of the Lord Advocate in Scotland; or in the name of an officer of the stamp office. Proceedings for the recovery of penalties under the customs and excise laws must be instituted and conducted by the proper officers, under direction and control of the commissioners. In a Q. T. action the penalty is usually shared by the Crown and by the Informer (q. v.).

Qui'to ('the deep ravine'), the capital of the republic of Ecuador, S. America, is situated on a fertile plateau 9492 feet above the sea, and only 15 miles S. of the equator. It is surrounded by mountains—twenty peaks, of which eleven are snow-topped, being visible from its streets. The site of Q. is exceedingly irregular, being intersected by numerous ravines (whence its name), which are spanned by arches, and on these many of the houses stand. The latter are for the most part built of sun-dried bricks, but the principal edifices are of stone. They include the cathedral, the palaces of the president and archbishop, the university (with 300 students), two hospitals, and several convents. The climate of Q. is delightful, the mean annual temperature being 59°. The average annual rainfall is 70 inches. The city is, however, very subject to earthquakes, in one of which, on 4th February, 1797, 40,000 lives were lost; while another, in March, 1859, caused damage to the extent of \$3,000,000. Q. has some not very important manufactures of coarse cotton and woollen articles, lace, jewellery, and confections. It also exports grain and metals to Peru and Europe through its port, Guayaquil (q. v.). Pop. 76,000.

Quit Rent is in England a small rent payable by tenants of manors in token of subjection. In ancient records it is called *white rent*, because paid in silver.

Quiver, a case for arrows slung from the shoulder or from the waist-belt. In ancient Egyptian paintings the Q. is represented strapped to the side of the chariot. Although leather arrow-cases were used in England during the Old English period, the name Q. (old Fr. *cuvire*) seems not to have come into use till the 17th c., and its origin is obscure.

Quoits (Icel. *kveita*, 'to throw violently'), a favourite game among the working classes of Great Britain, is played with a flat-iron ring about 9 inches in diameter, and having its outer edge sufficiently sharp to stick into the ground. This ring or quoit is projected with a whirling motion towards one of the *hobs* or *pips* which determine the range. Each player has two Q., and sides are formed and points made exactly as in bowling and curling.

Quorum (Lat. 'of whom'). Justices or Commissioners of the Q. are those whose presence is necessary to procedure in the Court. They are usually of greater experience or estate than the others. In Scotland, the word is used to denote the number of the nominees under a trust or similar deed, or of the judges of a Court, who must concur in an act, or be present at a meeting or court, to make the act, or business procedure, valid.

Quotidian Fever. See AGUE.

Quo Warranto, is an ancient writ calling on a person or corporation exercising any privilege to show by what authority they do so.

R.

the eighteenth letter of the English and Latin alphabet, corresponding to the Semitic Kesh and the Greek Rho. It belongs to the class of liquids, and its proper pronunciation is that of a trill, caused by the repeated closing and opening of the passage of air proceeding from the larynx. R seems to be a peculiarly difficult letter to pronounce, especially for Englishmen. The Scotch experience less difficulty, and the well-known 'burr' of Northumbrians is merely a dialectical exaggeration of the proper sound. Corrupt sounds may be represented by 'ry,' 'th,' or 'w.' In English, also, it must be observed that there is a mute or vocal R; e.g., 'door,' as vulgarly pronounced, is scarcely to be distinguished from 'daw,' or 'lord' from 'laud.' By the Romans, R was called the dog's letter—*irritata canis quod 'rr' quam plurima dicit*. In Greek, R when beginning a word had the mark of an aspirate, and was regularly doubled in the middle of words. In Latin, R was often used as a euphonic substitute for S; as *arbor* for *arbos*, and the form *Furius* is historically known to have taken the place of *Fusius* in the 4th c. B.C. R interchanges with L; as Tivoli for Tiber, *apôtre* for *apostolus*; sometimes also with D. The R in such Indian words as Guicowar (q. v.) is philologically, though not phonetically, a D.

As an abbreviation, R. stands for royal; R.A., either Royal Academician or Royal Artillery; R.S.V.P., *répondez s'il vous plait*, 'reply if you please'; R.I.P., *requiescat in pace*.

Ra was the third of the chief gods of Lower Egypt, and represented the sun, being the offspring of Pthah (the god of fire) and Neith (nature.) The temple of R. was at On, called Heliopolis (city of the sun). He was represented in human form, with the head of a hawk; in the hieroglyphics, by the sun's disc. His sacred animal was the bull.

Raab (Magyar, *Gzör*), a picturesque town of Hungary, in a wide marshy plain, at the confluence of the smaller Danube (a branch of the Danube), the R., and the Rabnitz, 70 miles S. E. of Vienna by rail. The seat of a bishop, it has a fine cathedral, nine other churches, two convents, an arsenal, &c. A large trade in grain and horses is carried on both by rail and steamer, and there are cutlery and tobacco industries. Pop. (1870) 20,035. The adjoining village of R.-Szigeth has 4500 inhabitants, almost all gardeners.—The *river* R. rises in the Noric Alps, near Gratz, has a course N.E. of miles, and joins the Danube six miles below the town of the same name.

Raa'say, an island of the inner Hebrides, county of Inverness, Scotland. It lies between Skye and the mainland, extends 14 miles in length and 3 in breadth, and attains its greatest altitude in Dunlan Mountain, 1500 feet above the sea-level. There is some arable land in the E. and S., but most of the surface is pasture and moorland. The ruins of Broichel Castle are situated on an almost inaccessible cliff in a small bay on the E. coast. The castle formerly belonged to 'John the Strong,' an ancestor of the present family of Macleod of Raasay. Pop. (1871) 389.

Rabat, a seaport of Morocco, on the left bank of the Bu-Regreb, the mouth of which forms a harbour enclosed by a bar, 115 miles E.S.E. of Fez. It is surrounded by walls, and has a decayed fort, *El-Mansur*, and an arsenal. The finest building is the Mosque of Hassan, in the best style of Moorish architecture, with a tower 192 feet high. The manufacture of carpets, mats, silk and woollen fabrics, laces, ropes, and earthenware, is actively carried on. The imports (cotton manufactured articles,

cutlery, and sugar) amounted in 1876 to £76,442, of which £72,888 came from Great Britain. The exports (chiefly wool) in the same year were valued at £41,468, of which Britain received £36,492. The amount of imports and exports in 1876 showed a decrease of 30 per cent. as compared with 1875, and of 25 per cent. as compared with 1874. In 1876 there entered the harbour 44 vessels of 12,322 tons, of which 23 of 9676 tons were British, and 6 of 1848 tons French. Pop. 20,000 (2000 Jews).

Rabb'a, a town of Africa, kingdom of Gando, on the left bank of the Niger, about 350 miles from its mouth. Formerly one of the chief slave-markets of the Sudan, it has suffered much of late years from tribal wars, but still has a considerable trade with Tripoli, Fezzan, &c., chiefly in ivory. It is noted for its fine horses. Pop. 40,000.

Rabb'i is a derivative from the Hebrew *rab*, a great man, one distinguished for age, position, office, or skill (cf. Job xxxii. 9), which is used in post-biblical Hebrew as a title for those distinguished for learning, the authorised teachers of the law, and the spiritual heads of the Jewish community. Various degrees of dignity are denoted by the addition of different suffixes to *rab*. Without any suffix, it corresponds to *master*, *teacher*. With the pronominal suffix, first person singular, R. (my master), it indicates a higher degree (cf. Matt. xxiii. 7, 8). The highest degree is indicated by the addition of the pronominal suffix, first person plural (Chaldee), *Rabboni* (our master). This was the title given to the patriarchs or presidents of the Sanhedrim, the first who obtained it being Gamaliel I. (patriarch in Palestine A.D. 30-50).

Rabbit (*Lepus cuniculus*), a familiar species of *Rodent* mammalia, belonging to the family *Leporidae*. It is distinguished from the hare by its smaller size, and by the hind limbs especially being better proportioned. Its colour is darker, and the ears are shorter and uniformly brown. The animal is gregarious, and in this respect also differs from the hare. It is not markedly intelligent, the hare being more susceptible of domestication and training. The R. is very prolific, and may produce three or four litters in a year. The number of young in each litter varies from four or five to twelve. They are hairless and blind when born. The food of the R. consists of a variety of vegetable substances, but the creature is very destructive to young trees, which it frequently kills by stripping off the bark. Rabbits are shot and trapped for the market in large quantities, the flesh being palatable and readily digested, especially when young.

The R. shows a striking tendency towards variation, a feature absent in the hare. Of the *fancy* varieties, the *Angora R.* is perhaps the most valuable. The skin of this breed is utilised in France for the manufacture of a delicate leather from which gloves and other articles are made. A species of R., well known in N. America, and different from the common R., is the *Lepus sylvaticus*, common in the Southern States of America. This species does not appear to live in burrows.

Law Regarding Rabbits in the United Kingdom.—The lord of a waste in England over which there is a right of Common (q. v.) may make R.-burrows in it, and the holder of the right of common must not kill the rabbits, however numerous they become, but he may bring an action against the lord for surcharging. Rabbits belong to the tenant of land, unless there is a contrary stipulation in the lease. The owner or tenant of land, or persons authorised by either, may shoot rabbits without a game licence. Others require a licence. In Scotland it is, by statute, theft to take rabbits from a warren, or to shoot them without the proprietor's permission. Though rabbits are not

game, they are protected against poachers, who may be arrested on the lands, and if necessary detained. See FORESTS, CHASES, PARKS, and WARRENS.

Rabbit-Skins form the raw material of more than one branch of industry. A silver-grey variety of the common rabbit is much valued in China on account of its fur, which there brings high prices. In Europe, again, the skins of both wild and tamed varieties of rabbits are extensively employed in the fur trade—not much, however, under the name of R.-S., but almost entirely as imitations of other and more costly furs. Thus white R.-S. do duty as ermine skins, and to imitate other furs the skins are suitably dressed, dyed, and prepared, the industry alone giving employment in Great Britain to no fewer than 2000 persons. In France certain long-haired varieties of rabbit—the Angora and the Cashmere—are greatly prized on account of the length of their fine silky hair, which ranges from 1 to 1½ inches. It is spun into a fine thread, which is woven into a kind of shawl much prized in the American market. The great proportion of R.-S., however, is used in the manufacture of fine felt hats, in which the French greatly excel. It is estimated that in France 60,000,000 R.-S. are collected annually, the hair of the greater part being used in the felt-hat trade, the remainder for imitation furs. As a fur material R.-S. are unsatisfactory, owing to the hair falling quickly away from the skin. A large number of R.-S. are now imported from the Australian colonies, which are so overrun by the animal that rewards are in some quarters offered for their extermination.

Rab'elais, François, the youngest son of Thomas R., an apothecary or innkeeper at Chinon, in Touraine, was born in that town about the year 1495. His earliest education was received at the village of Seully, whence he was despatched in despair at his laziness either to the convent of Baumette, or the university at Angers. Here he formed a friendship with Du Bellay, who afterwards became a cardinal. Under what impulse is not known, but R. chose the Church as his career in life, and entered among the Cordeliers of Fontenay-le-Comte, in Poitou, a mendicant order of friars. His residence lasted fifteen years, and was productive of two results. He gained an absolute knowledge of the scurrilities of monastic life, and he developed an enthusiasm for learning which rendered him one of the most scholarly men of his age. Many stories, utterly beyond verification, are told of mad pranks indulged by him at this time in contempt of priestly superstitions, but they must be accepted as after thoughts suggested by incidents in his writings. But his devotion to the masterpieces of antiquity brought him within the discipline of his superiors. Along with a companion, Pierre Lamy, he was indicted for the study of Greek, which was regarded as synonymous with the heresy of the Reformation. His books were confiscated, and serious punishment would have been awarded him had not influential friends intervened, and obtained from Clement VII. an indulgence by which he passed into the less exacting order of St. Benedict (1523), at the Abbey of Maillelais. Here he remained but a short time, finding the attractions of freedom and the world too strong for him. He was not, however, ostracised from the society of ecclesiastics, as he was received into the house of the Bishop of Maillelais, and there prosecuted, for an indefinite period, amidst the congenial companionship of scholars, a great variety of studies. It is told by Colletet that the range of his studies included philosophy, theology, mathematics, medicine, jurisprudence, music, arithmetic, geometry, astronomy, natural history, painting, and poetry. For some years traces of him are lost, though between 1524 and 1530 he probably attended at the Universities of Paris and Bourges. In 1530 he reappears as a student of medicine at Montpellier, where he ultimately (1537) qualified himself as a physician. Tradition has preserved a number of anecdotes concerning the life he led here, most of them indicating his devotion to horse-play, wine, and the grosser pleasures. Justice is also done to his extraordinary knowledge of languages, which probably included, besides the classics, Arabic, Hebrew, English, German, Italian, and Spanish. In 1532 he was at Lyon, labouring partly at medicine, but more especially at literary lack-work. The publishing establishment of Sebastian Gryphe secured his name for a number of works on medical, legal, and archaeological subjects as well as for some popular almanacks. It is to this period that must be referred the composition of two parts of *Gargantua et Pantagruel*, though the entire book was not published as we now have it until after his

death. It partakes of the character of romance, satire, and extravaganza. The principal heroes are moulded on colossal lines, and are based, many critics suppose, upon contemporaries. For example, in *Gargantua* they recognise the king of Navarre, and in *Pantagruel* Antoine de Bourbon. Such identification is far-fetched, and explains nothing as to the general movement of the story, which is arbitrary and capricious, a medley of satirical descriptions, of grotesque and serious philosophy, of wild and impossible adventure. In its details the regulating purpose is hard to find. Taken as a whole, however, it is meant to touch the society of the epoch at all points, an aim which his familiarity with every aspect of life rendered completely successful. From cloister to the throne no class escaped him. Each is assailed with the merciless strength of well-directed laughter. R. had a matchless exuberance of animal spirits, and on that very account *Gargantua* sometimes descends into inexcusable depths of coarseness. Yet at his worst he is robust and human rather than prurient and nasty. The book gave a strong impulse, though on the Pagan and sceptical side, to the emancipation of the human spirit from mediævalism. It takes rank as the earliest product of French prose bearing that subtle influence in the mechanical structure of sentence and in the fertility of vocabulary due to classical study. In 1534 R. joined Du Bellay as he passed southwards to Rome and acted as physician on his suite. From Italy he wrote a number of letters, published in 1651, and when there obtained reinstatement to the order of St. Benedict with authority to practise medicine. In that capacity he obtained a high reputation in Narbonne, Castres, and Lyon. He retired to the Abbey Saint Maur les Fossés in 1538, but his connection with it was not rigidly maintained, as he had free movement outside its walls. The death of François I. made R. a fugitive along with Cardinal Du Bellay, but in 1551, partly through the exercise of that tact and diplomacy for which he was famous, he obtained the curacy of Meudon. It is still matter of contention where and when he died, but the majority of voices pronounce for Paris, and the year 1553. See *F. R.* by Delécluze (1841); *R. sa Vie et ses Ouvrages* by Lacroix (1859); *R. et ses Ouvrages* by Jean Fleury (1877). But every episode of his life has had a monograph or a treatise devoted to it, until a vast expository literature has grown round his name.

Rab'ener, Gottlieb Wilhelm, a German satirist, was born at Wachau, near Leipsic, September 17, 1714. After studying at the College of Meissen, in 1734 he entered the University of Leipsic, where he devoted himself to the study of law. His special knowledge of financial matters led to his appointment in 1741 as inspector of customs for the Leipsic district, and to his being summoned to Dresden (1753), and nominated (1764) counsellor of customs to the king. He died at Leipsic, March 22, 1771. From 1741 to 1744 R. made many contributions to the *Beistigungen des Verstandes und Witzes*, and in 1744, together with Gaitner, Cramer, A. Schlegel, Schmid von Lübeck, Ebert, and Zachariae, established the *Brömer Beiträge*. R.'s contributions to these two journals make the first two vols. of his *Sammlung Satirischer Schriften* (Leips. 1751), to which he added a third vol. (*Satirische Briefe*) in 1752, and a fourth in 1755, and which went through ten editions prior to 1772. His *Freundschaftlichen Briefe* were edited with a life of the author by Weisse (Leips. 1772), who also issued a complete edition of P.'s works (6 vols. Leips. 1777; latest ed. by Ortlepp, 4 vols. Stuttg. 1840). R. had great influence in his own time, and was an important factor in the literary development of Germany. To some extent he took Lucian as his model, but in genius he came far short of his great original.

Rab'ies. See HYDROPHOBIA.

Rac'about, a farinaceous food said to be derived from the farina of the acorns of the Barbary oak, *Quercus ballota*, with some flavouring material. An imitation but superior article is composed of cocoa, potato starch, sugar, and vanilla, and is used like cocoa.

Racalmu'to, a town of Sicily, province of Girgenti, on an affluent of the Platani, 15 miles N.E. of Girgenti. It is of Saracenic origin, and was long under the Chiaramonte family, whose castle is 2½ miles distant. Hitherto a notorious haunt of brigands, it is rapidly improving, and is developing a trade in fruits, sulphur, gypsum, and saltpetre. Pop. (1874) 12,250.

Racooni'gi, a town in the province of Cuneo, in N. Italy, 23½ miles S. of Turin by rail. It is well built, and has a park, 1¼ miles long by ¾ of a mile wide, laid out by Le Nôtre in 1755, and a château which was the favourite residence of Carlo Alberto. Pop. (1874) 9912.

Race (Old Eng. *ras*, 'rapid course,' 'stream'), a name sometimes given to the current produced by the meeting of two tides, as the R. of Portland, the 'R. of Alderney.' The term R. (*cf.* Old Fr. *rase*, 'a mill-stream') is also applied to the stream which turns a mill, the part below the wheel being called the *tail-R.*, while the *head-R.* is the watercourse above it. —In *weaving*, R. denotes the ledge in the batten or lay by which the shuttle conveying the weft passes through the decussation or 'shed' of the warp threads.

Racehorse, a breed of horses noted for the delicacy of their form, and for the muscularity and suppleness of their limbs. The body is long and slender, the neck being especially long and prominent. It is generally admitted that the Arab breed has greatly contributed to the formation of the R. variety. See HORSE-RACING.

Raceme (Lat. *racemus*, a 'bunch' or 'cluster of berries') is an inflorescence (q. v.) in which the flowers are borne on pedicels along a single undivided axis or rachis,—as, for example, in the hyacinth and currant.

Racemic Acid. See TARTARIC ACID.

Rachel, Elizabeth Rachel Felix, the greatest of modern French tragédiennes, was the daughter of a Jewish pedlar, and was born in the Canton of Aarau, Switzerland, March 24, 1821. In early childhood she sang with her sister Sarah in the streets of Lyon, and subsequently in Paris. In the French metropolis the two children attracted the notice of a wealthy patron, who placed them both in the conservatory of sacred music. R. made her first appearance at the Gymnase, April 24, 1837, and next year obtained an engagement at the Français. Her success was complete. Jules Janin recognised her genius, and the Parisian public received her with enthusiasm. The classical drama of France was almost revived for her. Among her most powerful impersonations were Camille in *Les Horaces*, Roxane in *Bajazet*, Athalie, Joan of Arc, Hermione in *Andromaque*, and notably Phèdre. She triumphed in London in 1841, in St. Petersburg in 1853, and in the United States in 1855. In the latter year her health gave way, and after seeking recovery in vain in the Havannah and Egypt, she died of consumption near Cannes, 3d January 1858. An English memoir of R. was published in the year of her death. In person she was slender and lissome, pale in countenance, with features capable of marvellous transformation. Her action was graceful and nervous, and the effect of her elocution was thrilling and electric. She had little tenderness, but in scenes of rage and passion her power was overwhelming. G. H. Lewes, in his book *On Actors and the Art of Acting* (1875), describes her as 'the panther of the stage.'

Rachis (Gr. 'the spine') is the axis of Inflorescence (q. v.). The term is also applied to the common petiole of compound leaves, and to the stalk or stalks of the frond in ferns.

Racine, Jean, was born at Ferté-Milon, December 21, 1639, and in his fourth year lost both father and mother. He then passed to the care of his maternal grandfather, in whose house he had long the freedom of neglect until he was sent to the College of Beauvais. Here he remained until his sixteenth year, and obtained a competent knowledge of Latin. On the death of his guardian he was introduced to a school in connection with the community of Port-Royal, and under Claude Lancelot, the sacristan, gained a scholarly acquaintanceship with Greek. But his enthusiasm for the splendours of Pagan literature was considered dangerous to his spiritual life, and it is recorded of his teacher that he delivered to the flames a copy of *Theagenes and Charicleia*, which he captured in the hands of his pupil. Being discovered in the act of perpetrating secular rhymes of his own, he was forthwith set to turn into French verse the Latin text of the Breviary hymns. R. next (1658) studied at the Collège d'Harcourt with the view of adopting either law or the church as a profession. On the marriage of the king in 1660, he published *La Nymphé de la Seine*, for which he was rewarded by Colbert sending him 600 livres, and by Chapelain pronouncing the

verses 'bien-tournés.' The circumstance gave a bias to his whole life. He cultivated the society of wits and worldlings and lost taste for professional pursuits, whilst at the same time he gave himself freely up to pleasure. But in 1661 he went to an uncle's at Languedoc, where he applied himself to theology with the view of succeeding his relative as a canon of St. Geneviève at Uzès. Twenty-three letters of his correspondence with La Fontaine and others survive from this period, which reveal his intense enthusiasm for secular study and his yawning weariness with theology. By 1663 he had returned to Paris, and had made the acquaintanceship of Molière and Boileau, attracted anew the attention of the court by his ode *La Renommée aux Muses*, and with his *La Thébaïde* commenced the life of dramatist in serious earnest. R. throughout his dramatic career wrought under the conditions of time, place, and action prescribed by the greater models which he imitated, though he relaxed the rules to the extent of making both time and place indefinite. His characters were not studies from life, having the variety and range of humanity with its innumerable moods. They were beings impelled by one dominant passion, which it was his invariable aim to follow out to a climax. In that respect he followed the law of Corneille; but instead of giving heroic proportions to his men and women, he kept them, though finely idealised, to the earth, limiting their development to the qualities of tenderness or nobility with which he endowed them. In 1665 appeared *Alexandre*, in which there are marks of rawness, but two years later *Andromaque* revealed, in full strength, the depth and moral grandeur of his studies in character, the pathetic reaches of which he was capable, and the transports of passion purified by ethical and intellectual virtues which it was in his power to portray. Here, too, he showed for the first time his flawless taste in phraseology, his high capacity for marshalling the objects of the drama, and in proportioning their language and actions whilst conducting them from point to point of a well-arranged plot. In 1668 appeared *Les Plaideurs*, an inferior comedy, *Britannicus* (1668), *Bérénice* (1670), *Bajazet* (1672), *Mithridate* (1673), all of these works showing how extensive were his resources, both historical and reflective. *Iphigénie* (1674) and *Phèdre* (1675) brought his labours to a close for a number of years. Disgusted by the attacks of a literary cabal, headed by the Duchess of Bouillon, and influenced by his friends the Port-Royalists, he resolved to adopt the life of a monk. He took a v. c. instead (1677), became king's historiographer, having already (1673) become a member of the French Academy, educated his own children, and grew wholly reconciled to that religious life from which he had formerly lapsed. In 1689 he wrote *Esther* for the nuns of St. Cyr, and in 1691 *Athalie* followed; and after his abandonment of the theatre he did not scruple to write malicious epigrams against contemporary dramatists. His relation to the 'Grand Monarque' was that almost of a personal friend, until his 'disgrace,' the causes of which are lost in mystery. He died April 21, 1699, and was buried in the cemetery of Port-Royal, from which, in 1711, his body was removed to the church of St. Étienne du Mont. See *Mémoires*, by his son Louis Racine (born 1692, died 1762); Aime Martin's *Commentaires*; Sainte-Beuve's *Causeries du Lundi*; Villemain's *Cours de Littérature*; Saint-Marc Girardin's *Cours de Littérature Dramatique*. All the later editions of R.'s works have been based upon that of Aimé Martin (6 vols. 1820-21). The best of these are Mesnard's (8 vols. Par. 1865-73) and Saint-Marc-Girardin (Par. 1870 et seq.).

Racine, a town of Wisconsin, U. S., 23 miles S. of Milwaukee, on the Chicago and Milwaukee railroad. It stands on Lake Michigan at the mouth of the Root River, and has an excellent harbour, 24 churches, 4 newspapers, and large manufactures of machinery, &c. R. College in 1875 had 18 instructors and 180 students. Pop. (1876) 9880.

Rack (from Old Eng. *recan*, 'to stretch out'), an engine of torture consisting of an oblong frame of wood with four beams, to which a sufferer was bound. By the application of machinery, his limbs could be subjected to such a strain that dislocation might ensue. The R. is at least as old as the Roman Empire. During the Middle Ages it was employed in every part of Europe. The Inquisition, in particular, has an evil fame in connection with its employment for extracting a confession or recantation of heresy; but the Tudor kings were as remorseless as the followers of Torquemada. This barbarous mode of obtain-

ing evidence has long been abandoned even in the most despotic countries.

Rack, a straight bar with teeth on its edge arranged so as to gear with those of a wheel, pinion, sector, or with a worm. A segment *R.* has its pitch-line curved. The cut shows a double *R.* motion adopted in double-barrelled air-pumps; by turning the handle the spur-wheel is made to impart reciprocating rectilinear motion to the *R.* on each side.

Rack'ets (Fr. *Raquette*), a ball game played after the manner of Fives (q. v.), only a stringed battledore is used for striking the ball instead of the open hand.

Rack Rent is in England the full annual value of land.

Racoon, or **Raccoon** (*Procyon lotor*), a species of *Carnivorous* quadrupeds belonging to the *Versivæ* or bear family. It occurs in N. America, and derives its specific name of *lotor* or 'washer' from the prevalent belief that it dips its food in water before eating it. The *R.* is of greyish colour; the top of the head is dark brown, and the tail short, bushy, and marked with blackish rings. The fur, which is woolly, is highly valued. The animal subsists on miscellaneous food, but exhibits a preference for vegetable food. It eats shell-fish and crabs readily, and is dangerous to poultry-yards. The average size is that of a small fox. *R.* hunting is a favourite pastime in America, the animal exhibiting much dexterity in escaping from its pursuers, and attacking the dogs fiercely when brought to bay. The young number two or three, and are born in May. The Agoura or Crab-Eating *R.* is the *P. cancrivorus* of naturalists. It inhabits tropical and S. America.

Radcliffe, a manufacturing town of Lancashire, on the Irwell, 2½ miles S.S.W. of Bury by rail, has five churches—the ancient parish church of St. Bartholomew, St. Thomas (1864), St. John, St. Paul (1875), and St. Andrew (1877). A market-hall was presented to the town in 1852 by the Earl of Wilton, and a co-operative hall, with store-rooms, library, and assembly room, has been erected in 1878 at a cost of £12,000. There is one weekly newspaper, and cotton-spinning, gingham and fustian weaving, bleaching, dyeing, and paper-making, form with coal-mining the principal industries. Pop. (1851) 5002; (1871) 11,446.

Radcliffe, Anne, an English novelist, was born in London, July 9, 1764. Her maiden name was Ward, and at the age of twenty-two she married Mr. William Radcliffe, who became editor and proprietor of the *English Chronicle*. Her first novel, *The Castles of Athlin and Dunbayne* (1789), was only remarkable for the wild improbability of its plot; the *Sicilian Romance* (1790) was nowise better; but the *Romance of the Forest* (1791), a tale founded on a French *cause célèbre*, evinced a power of description and a facility of invention the like of which had not been seen for many a day. Mrs. R.'s next tale was her best, *The Mysteries of Udolpho* (1794). Montoni, the bandit chief in that work, is one of the weirdest characters of fiction, and everything is in keeping with him, terrific and melodramatic. Mrs. R.'s popularity with our grandfathers can scarcely be conceived by us; but we must remember that, with some help from Horace Walpole and Clara Reeve, she practically revived the romance. Had her faults not been a hundred times exaggerated by imitators from Monk Lewis downwards, we should sneer less at her wax ghosts, lofty-souled desperadoes, castles full of interminable dungeons, and other puerile horrors. In 1795 this authoress published a *Journey through Holland*, and two years later appeared her last novel, *The Italian*, full of racks, confessions, inquisitions, and lightning. Her posthumous romance, *Gaston de Blondeville*, was edited by Talfourd in 1826; and in 1834 her poems, many of them taken from her novels, were collected. Mrs. R. died in London, February 7, 1823. Fifty years ago her books were the standard amusement of old and young; now we wonder even at the words of Dunlop:—'Life has few better things than sitting at the chimney corner in a winter evening and reading such absurdities.'

Radcliffe, John, M.D., was born at Wakefield, Yorkshire, 1650. He graduated at University College, Oxford, in 1671, and after a course of study in medicine began to practise in Oxford. In

1682 he took the degree of M.D., and two years after he removed to London, where he quickly obtained an extensive practice. In 1686 he was appointed principal physician to the Princess Anne, and in 1713 he was elected M.P. for the town of Buckingham. Many stories are told of his witty sayings and eccentric doings. In the last illness of Queen Anne he was sent for; but, knowing the case to be desperate, he excused himself from attendance on the ground of indisposition. Her Majesty died the day after this refusal was given. A motion of censure on *R.* was passed in the House of Commons, and the severe criticism of the public on his conduct deeply affected his mind. He died November 1, 1714. He never published anything, but left his fortune to found the well-known *R.* Library at Oxford (1737-49), which is now used as a reading-room to the Bodleian. This library, now absorbed in the Bodleian, was especially rich in books on the physical sciences, architecture, and some sections of archaeology. Garth, alluding to *R.*'s lack of acquaintance with literature, remarked that for him to found a library was as if a eunuch should establish a seraglio. See *Libraries and Founders of Libraries*, by Edwards (Lond. 1864).

Radegunda, Saint, daughter of Berthar, a prince of Thuringia, was born in 521, and in her eighth year carried prisoner to Soissons by the Frankish king Hlothar. Placed for education at Athies in the Vermandois, she became devoted to Christianity. In 538 she was forced to become one of the wives of Hlothar. The king's putting to death her brother, who had been taken captive along with herself, decided *R.* to leave her husband and become a nun, first (544) at Orleans, then at Tours, and finally at Poitiers, where she founded the Abbey of the Holy Cross about 550, and gathered around her 200 nuns, whom she employed in reading and transcribing MSS. She died 13th August, 587.

Radetzky, Johann Joseph Wenzel, Count, a distinguished Austrian general, was born at Trzebnitz in Bohemia, 2d November, 1766, became a cadet of Hungarian cavalry in 1784, and first served in the Turkish campaign of 1788-89. His conduct in the wars against France in the Netherlands and the Rhine (1792-95) gained him the rank of major in 1796, and he fought brilliantly against Napoleon at Aspern and Wagram in 1809, and at Kulm and Leipzig in 1813. In 1831 he became commander-in-chief of the Austrian army in Italy, and received the baton of field-marshal in 1836. The bitter hatred with which the Italians regarded Austrian dominion breaking forth suddenly in the rebellion of 1848, *R.* was at first obliged to retire from Milan before the superior forces of the insurgents, but was reinforced at Verona, and immediately inflicted upon the Italians the severe defeats of Montanara and Curtatone. Defeated at Goito by Carlo Alberto, he took advantage of the enemy's delay by rapidly raising his force to 82,000 men, and after driving the king from Custozza, was again victorious under the walls of Milan, 4th August 1848. After a six months' armistice, the war began again, and *R.*, in spite of his old age, at once advanced into Piedmont and finally routed the Italians at Novara, 23d March 1849. This victory he immediately followed up by the bombardment and recapture of Venice. As governor-general he maintained a stern, jealous guardianship over Lombardy and Venice till his death at Milan, 3d January 1858. See *Der Österreich. Feldmarschall Graf R. von einem Österr. Veteranen* (Stuttg. 1858), and Prince Trubetzkoi's *Campaigns of Marshal R.* (Leip. 1861).

Rádhampur, the capital of a native State of the same name in Gujerat, India, in political connection with the Government of Bombay, 85 miles N.W. of Ahmedabad, and 270 S.E. of Hyderabad in Scinde. Pop. (1872) 13,910.—The State of *R.* lies between Kattywar and Rajputana. Area, 833 sq. miles; pop. (1872) 91,579; revenue, £50,000; army, 248 horse and 362 foot. The soil is flat and fertile, and produces excellent wheat and cotton; other products are cattle, saltpetre, and unbleached cotton cloth. The tribute of £1700 was remitted in 1825, and an equal amount is now paid to the State in compensation for the loss of its salt-works. The chief is a Nawaub of Persian descent, whose family dates back 250 years.

Radial Artery, the almost direct continuation of the *Brachial artery*, or main artery of the arm. It commences just below the bend of the elbow, and passes along the radial side of the forearm to the wrist, where it is felt as the pulse. The

ulnar artery is larger than the radial, and is given off from the brachial artery close by the origin of the radial vessel. It also lies deeper in the forearm.

Ra'diant Energy. The recognition of Energy (q. v.) as a something which has as true an existence in the physical universe as matter, has resulted during the last thirty years in a rapid development in all branches of science. Energy cannot be regarded as a property merely of matter; indeed, the most plausible theory of the ultimate nature of matter, the vortex theory of Sir W. Thomson, suggests that matter, *as we know it*, is a form of energy. Laying aside such hypotheses, however, the physicist recognises matter and energy as distinct, but yet so related that we know of the existence of either only by means of the other. We perceive an object solely by reason of certain transformations of energy which are inseparable from it. Energy is the active agent which works through matter; matter is in itself passive, and is that by which we recognise the workings of energy. It is now an accepted truth in physics that when energy passes from any one system of bodies to any other it must pass through a material medium—that, in other words, action at a distance is unphilosophical, because of necessity making other and less admissible assumptions than are required for action through a medium. Light is understood to depend physically upon a certain undulatory motion executed in the ether. What is commonly called radiant heat differs from light only in the greater length of its wave-lengths, and to the same category belong the actinic rays, whose wave-lengths, though too short to affect our eyes, produce such miracles in photography. All these forms of energy are conveniently grouped under the name R. E. They are of the same nature and are subject to the same laws. They move in straight lines with the same velocity, they are reflected and refracted in precisely the same way, and they can all be polarised. It is thus evident that radiant heat resembles light more than that which we ordinarily understand as heat. Indeed, we have no reason to regard it as heat. All we can say is, that when a body receives this kind of radiation, certain effects are observed which are usually regarded as effects of heat, implying at most, however, a transformation of R. E. into heat. The laws of radiation and the consequences of Prevost's theory of exchanges are considered under HEAT and SPECTRUM ANALYSIS.

Radia'ta ('rayed animals'), one of Cuvier's four great divisions of the animal world. As now used, the term widely differs from its former meaning. Cuvier regarded the Radiate animals as the lowest, and as including the three modern sub-kingdoms known as *Protozoa*, *Coelenterata*, and *Echinozoa* or *Amnibolia*. Cuvier's division was therefore a very heterogeneous assemblage of animal forms, which the progress of research has separated into distinct divisions, and into certain plain types of animal structure. The most typical members of Cuvier's Radiate group were the *Echinodermata* (star-fishes, sea-urchins, &c.). The term R. is not much employed in modern zoology, but when used is synonymous with *Echinozoa*. The symmetry of the bodies of these animals, as well as of *Coelenterates*, exhibits a *radial* disposition of parts; i.e., the ideal elements of the body are arranged radially around a central point, most frequently represented by the mouth.

Rad'ical (Lat. *radix*, 'a root'), a term which first came into use about 1830 to designate the advanced Liberal party in English politics. It is a contracted form of 'R. reformer.' There are several subdivisions of radicalism, notably the 'philosophical radicalism' of such men as Bentham and the two Mills, and radicalism of the 'Manchester school,' represented by Cobden, Bright, and their followers. The word 'radical' is now used in several European countries (e.g., France) to designate politicians of the Extreme Left.

Ra'diolites, a peculiar fossil genus of *Lamellibranchiate* Molluscs belonging to the family *Hippuritidae*, and occurring in the Cretaceous rocks exclusively. The shell is inversely conical in shape, and its valves are dissimilar.

Radiometer, a very delicate instrument, invented by William Crookes for showing certain remarkable phenomena of apparent repulsion and attraction discovered by him. In a very perfect vacuum four light vanes are suspended horizontally and radially, like the vanes of an anemometer, so as to be capable of free rotation round a vertical axis. Each disc or vane

has its one side white and its other side black, so that when the system is rotating, all the discs are moving in the direction of similarly coloured sides. When in the dark, the system is motionless; but when it is brought into the light, the vanes begin to rotate in a definite direction. Any source of light and heat brought near it acts so as to repel the blackened surface of the disc which is facing it. The true agent is radiant heat, which raises the temperature of the blackened surface higher than that of the white surface. The effect of heat upon the molecules of a gas is to make them go faster; and hence the molecules still present (for an absolute vacuum is not possible) rebound off the blackened surface with greater velocity than off the other, and the recoil forces the vanes round. The true explanation was arrived at independently by several physicists; and Stokes has done much to elucidate many curious and at first sight contradictory phenomena in connection with it.

Rad'ish (*Raphanus*) is a genus of cruciferous plants numbering six well-marked species, of which the esculent in common cultivation is the most important. The genus is distinguished from its congeners by its elongated pod being either one-celled and many-seeded; or transversely jointed, the joints being one- or two-celled, and the cells one-seeded. The origin of the garden R. (*R. sativus*) is, like that of so many of our cultivated vegetables, a doubtful question; but we know that it was grown at an early period in Egypt, and that for ages it has been cultivated in India and China. Into Britain it was introduced upwards of three centuries ago. The original stock has given rise to numerous varieties, which are divided into long-rooted or spindle-shaped, and round or turnip-rooted. They are also called spring, summer, autumn, or winter radishes, according to the season in which the respective sorts are found best adapted for use. The R. is generally used as a salad vegetable, but the roots are sometimes used boiled, and a few years ago a great sensation was created by the introduction of a Japanese form of the species which grew into a bush producing pods nearly a yard long. In this case the young pods were the part eaten, and the plant obtained the name of the rat-tail R. (*R. caudatus*). A common agrarian weed of this genus is named *R. Raphanistrum* or jointed Charlock. The name is derived from the Lat. *radix*, implying a plant valued for its roots.

Ra'dius, in geometry, is a straight line drawn from the centre of a circle to the circumference. In astronomy, the line which at any instant connects the planet with the centre of force is called the *R.-vector*, or sometimes simply the R., and from this use of the word it has been extended to the variable line, which, with its one extremity fixed at the origin or pole, sweeps out a curve. See CO-ORDINATES, and POLE.

Ra'dius, one of the two bones existing in the forearm of man and other Vertebrate animals, and lying, when the arm is in the supine position, to the thumb-side of the limb. By the movements of the radius on the ulna and humerus, the forearm can be readily turned or rotated. The exact representative of the R. in fishes has not yet been determined. In birds the R. is the smaller of the two bones of the forearm, but in most other Vertebrates it is the more constantly developed. In the horse, for example, the R. is large, whilst the ulna is rudimentary. In the frog and camel, again, it attains a large development, the ulna, its companion bone, being fused with it.

Rad'norshire, a border county of S. Wales, is bounded N. by Montgomery, E. by Salop and Hereford, S. by Brecknock, and W. by Cardigan. Area, 276,552 statute acres; pop. (1871) 25,430. The surface, of Silurian formation, is everywhere intersected by hills, which attain in Radnor Forest an elevation of 2163 feet, and send down numerous tributaries to the Wye, the southern boundary of the county. In 1876 there were 23,874 acres under corn crops, 8199 under green crops, 16,539 in clover, sainfoin, and grasses, 103,343 in permanent pasture, exclusive of heath and mountain land, and 8523 woods. R. had (1876) 8212 horses, 30,937 cattle, 282,988 sheep, and 6734 pigs. Oats, hay, wheat, barley, and turnips form the principal crops, and are grown chiefly in the south-eastern district. R., which is an English-speaking and purely agricultural county, returns one member to Parliament. Presteigne, with a pop. (1871) of 1910, is the county town, other places being New Radnor (pop. 517), Knighton, and Rhayader, which conjointly return one member to Parliament.

Rad'om, a government of S. Poland, surrounded by Kielce, Piotrkov, Warsaw, Siedlce, Lublin, and Galicia. Area, 4769 sq. miles; pop. (1872) 541,993. P. is drained by the Vistula and its affluent the Pilica. In the S. the Lysa Gora and Lysica rise to 2066 feet. In 1872 the corn reaped in R. amounted to 1,471,670 qrs., potatoes raised to 6,857,374 bushels. 4242 workmen were employed in manufactures, producing iron, spirits, beer, sugar, leather, porcelain, &c., to the value of £748,216.—**R.**, the capital, on the Meczna, has considerable trade and manufactures. Pop. (1870) 10,944.

Rad'owitz, Joseph Maria von, a Prussian general and statesman, born at Blankenburg, Brunswick, 6th February 1797. He was of a noble Catholic family, originally Hungarian. Educated in Paris and at Cassel, he became in 1813 an officer in the Westphalian artillery, and was wounded at the battle of Leipzig. After the peace he became a teacher of mathematics and military science in the Cadet Institute at Cassel, but in 1823 went over to the Prussian service, in which he became chief of the Artillery Staff. Meanwhile he had (1828) married the Countess Maria von Voss, and had formed a close and lasting friendship with the Crown Prince, afterwards Friedrich Wilhelm IV. He now began to assume a place in the front rank of anti-revolutionary politicians, and went hand in hand with the Ultramontane party, though towards the close of his life his position in this respect was a good deal modified. After the Revolution of 1848 he was actively concerned in the unsuccessful attempt to reconstitute the German confederation through the alliance of the three kings. In the autumn of 1850 he was for about six weeks Minister for Foreign Affairs. He died at Berlin, 27th September 1850. R. was an author as well as a statesman, and wrote on politics, mathematics, and military science. See Frensdorff, *Joseph von R. Eine Charakterschilderung* (Leips. 1850).

Rae'burn, Sir Henry, son of a manufacturer, was born at Stockbridge, Edinburgh, March 4, 1756. At the age of six he was an orphan, and at fifteen he left school and became apprentice to a jeweller. His caricature drawings drew attention in the shop of his master, and ere long he was doing some business as a miniature painter. Martin, the portrait painter, lent him pictures to copy; his master absolved him from his apprenticeship, and he devoted himself entirely to painting. Sketching in the fields one day, he put on canvas the figure of a young lady who had sauntered across the scene. Not long afterwards, he was pleased to receive a visit from the same young lady, who gave an order for her likeness. Ultimately she became his wife, and brought him a handsome fortune. Thus provided with means, he visited London, where he was warmly received by Reynolds, in whose studio he worked for about two months, and after studying for two years in Italy he settled in Edinburgh (1787), where he worked enthusiastically to the end of his life, making a yearly income of many thousand pounds. He was elected an R.A. in 1815, and was knighted by George IV. in 1822. He died 8th July 1823. There can be no doubt that R.'s style is modelled on that of Reynolds. Adopting Reynolds' great principle of making breadth—the effect produced by massing and keeping the lights and shadows as far as possible apart—the leading element in a picture, he carried out the principle in a manner and with a feeling peculiarly his own, rejecting thick impasto, and adopting a low tone and a sharp touch while working the colours with little unctuous admixture. Wilkie, when in Madrid studying the Spanish works, in noticing those of Velasquez, repeatedly alludes to his simple and powerful mode of treatment as always reminding him of R.'s works. In likenesses of men, his veracity has proved an immense boon to subsequent generations; for he lived in the time of Edinburgh's glory, and was intimate with its greatest men. His works are admirably supplemented by Cockburn's *Memorials of His Times*. His portraits of Lord Braxfield, Lord Newton, Cockburn, Francis Horner, Mackenzie, Robison, Robertson, Sir Walter Scott, are all very well known and highly prized. An interesting exhibition of his paintings was held at Edinburgh in 1876. See *Portraits of Sir Henry R.*, in autotype, with Memoir of the painter, by Dr. John Brown (Edin. Elliot, 1873).

Raff, Joachim, a modern German composer, born at Lachen, Switzerland, May 27, 1822. He was devoted to literature and science in his youth, but about 1843 began to publish a number of fantasias, caprices, rondos, &c., for the pianoforte, and their success induced him to renounce school teaching for

musical composition. Soon afterwards he produced the opera of *König Alfred* at Weimar without much success. He belongs to the Wagner school, and has glorified his master in his book *Die Wagnerfrage*. His pianoforte compositions number over 200, and he has also written songs and concerted pieces. His fame, however, rests principally on his symphonies, particularly those entitled *Leonore* and *Im Walde*, which are rich in fine effects of instrumentation and orchestral colour.

Raffles, Sir Thomas Stamford, a traveller and naturalist, was the son of a captain in the W. India trade, and was born at sea, off Jamaica, 5th July 1781. While a clerk in the East India Company he was sent as assistant-secretary to the new government of Pulo-Penang in 1805, and having acquired a knowledge of Malay, was appointed official interpreter. In 1807 he became principal secretary and registrar of the court of judicature, but was forced by illness to retire to Malacca in the following year. Acting partly on his advice, Lord Minto captured Java from the Dutch in 1811. Appointed lieutenant-governor, R. ably conducted the administration for five years, abolishing slavery and conciliating the native princes. In 1816, on account of ill-health, he returned to England, where he received the honour of knighthood and published his well-known *History of Java* (2 vols. 4to, 1817). After Java was restored to the Dutch, he was made lieutenant-governor of Fort Marlborough settlement, Bencoolen, on the Sumatra coast (1817), where, except during several months while engaged in forming the new settlement at Singapore, he remained till 1824, when illness again drove him back to England. While on the voyage the vessel took fire, but the passengers and crew escaped in the boats. Sir Stamford thus lost a valuable scientific collection and most of his other effects. Before leaving he had published *Malayan Miscellanies* (2 vols. Bencoolen, 1820-22), and endowed a college at Singapore for the study of Malay and Chinese, and on his arrival in England he founded and became first president of the Zoological Society. He died in London, 4th July 1826. See a *Memoir* by his widow (1830).—**Thomas R., D.D., LL.D.**, cousin of the preceding, born in London in 1788, was long an able preacher in Liverpool, and published several very popular hymns. He died 18th August 1863, and his biography, written by his son, Thomas Stamford R., appeared in 1864.

Rafflesia is the type genus of the curious parasitical plants constituting the small natural order *Rafflesiaceae*, natives of tropical Asia and S. America. The name was given by Robert Brown in honour of Sir Stamford Raffles, who, during his governorship in the East, discovered (1818) in the interior of Sumatra the wonderful *R. Arnoldi* as a parasite upon the roots of *Cissus angustifolia*. This plant bears no leaves, but consists of a single gigantic flower, measuring a yard across, and estimated to weigh 15 lbs., while its cup-shaped perianth is calculated to contain six quarts of fluid. The flower is of a mottled flesh colour, and after remaining expanded a few days begins to putrify, emitting a carrion-like odour attractive to insects, and thereby probably conducive to fertilisation. Three other species of R. are known to botanists, of which *R. Patma* is employed in Japan as an astringent and styptic. The principal S. American genus of this order is *Platyles*, natives of Brazil and Chili.

Rafn, Karl Christian, a celebrated Danish philologist, was born 16th January 1795, at Brahesborg in Fyen. After studying law at Copenhagen University (1814-16), he became sub-librarian there (1821-23), and a professor in 1826. From his early youth R. had been a student of Icelandic, and in 1821 he began to publish in a Danish translation a collection of old Scandinavian mythic and romantic sagas (*Nordiske Kjempehistorier*, 3 vols. Copenh. 1821-26; 2d ed. 1829-30). In 1825 he founded the Early Scandinavian Text Society, as secretary of which he edited a large number of important works, among the chief of which are his editions of the *Krakkunni* (Copenh. 1826); *Fornaldar-Sogur Nordrlanda* (3 vols. 1829-30); and *Færeyinga-Saga* (1832). For the great collection of the *Fornmannna-Sogur* (12 vols. 1829 et seq.) R. edited a large part of the text, and wrote the parallel Danish translation of the three first and the eleventh volumes. In his elaborate *Antiquitates Americanae* (1837) he clearly proved that America had been discovered by Scandinavians in the 10th c., and that between the 11th and the 14th centuries they had settlements in the lands now called Rhode Island and Massachusetts. In conjunction with Finn Magnussen, R. wrote *Grönlands Historiske*

Mindesmarker (3 vols. 1838-45), and part of *Antiquités Russes* (2 vols. 1850-52). He died at Copenhagen, 20th October 1864.

Raft (Dan. *raft*, 'a spar or pole') is the name given to an assemblage of pieces of timber fastened together to act as a float. When the R. is composed of timber sawn into marketable shape, and joined simply for convenience of transport down a river to the shipping port, it is called a *lumber R.* Rafts in some places are employed to carry freight; and in many cases of emergency at sea, poles and spars require to be lashed together for the purpose of saving life. In some large ships, precautions are taken against disaster in the provision of life-rafts of ingenious construction, based principally on the American tubular system. The American life-R. originally consisted of a collapsible material, such as indiarubber, which had to be inflated before launching; but now metal tubes have been adopted, two or three being connected by girders, between which air- and water-tight tanks for holding provisions are fitted. These tanks have screw taps at top and bottom, so that it is immaterial which side of the life-R. falls uppermost. Christie's and Roper's cellular life-rafts of metal and wood are recent important English additions to the means of saving life at sea. They are carried stretched across the deck, parallel to the captain's bridge, and they may be launched from either side of the ship.

Rafters, in building, are inclined timbers of a Roof (q. v.), to which is secured the lathing for the support of the slates or other covering. The feet of the R. rest on the wall-plate, and the heads abut at an angle against each other or against a ridge-plate running along the top of the roof.

Ragged Schools are supplementary of Industrial Schools (q. v.), from which they differ only in being founded and maintained by voluntary contributions. Such schools are intended to provide education for vagrant children, and to supply means whereby they may be prevented from lapsing into crime. The first ragged school was perhaps that of John Pounds, the poor cobbler of Portsmouth, who, from about 1819, continued to teach destitute children till his death in 1839. The Ragged Sunday School of London was founded in 1838, and later converted into a free day-school; the Field Lane School was established in 1843. The first schools at which food was supplied to the children were those opened by Sheriff Watson in Aberdeen in 1841, and by Dr. Robertson in Edinburgh (the Vennel) in 1845. Dr. Guthrie's *Plea for R. S.* gave an impetus to the movement, which led to the establishment of such schools throughout the country. A grant of £2, 10s. per head was allowed by the Privy Council in 1856, but withdrawn in 1859, and since then R. S. have received no aid from the State. The Education Acts (1870 and 1872) introducing the principle of compulsory education have caused many ragged day-schools (especially in England) to be changed to public schools. The question of further undertaking the burden still resting on the voluntary R. S. is at present being forced on the attention of school boards. In the United States the only similar institutions are orphan asylums. Of these, the chief, Girard College in Philadelphia, founded in 1848, contained as many as 550 orphans in 1875.

Raggee (*Eleusine Corocana*), a dark and very small-grained species of millet, which forms the staple of the food of the poorer classes in the central plateau of S. India. It is grown as a 'dry-crop,' i.e., on unirrigated land. Its chief merit is its great productiveness, for it is neither very palatable nor very wholesome. In Mysore, however, it is universally preferred to rice as an article of diet.

Raglan, Fitzroy James Henry Somerset, Lord, a younger son of the fifth Duke of Beaufort and of a daughter of Admiral Boscawen, was born 30th September 1788, and educated at Westminster, which he left in his sixteenth year to join the 4th Light Dragoons. In 1807, after proceeding to Constantinople with the British ambassador, he joined the staff of Sir Arthur Wellesley as aide-de-camp, and went to Copenhagen with him. During the Peninsular War he distinguished himself at all the remarkable battles, and became military secretary to the commander-in-chief. At the restoration of the Bourbons in 1814 he acted as secretary to the embassy at Paris for some months, and married Emily Wellesley, niece of the Duke of Wellington, whose military secretary and aide-de-camp he again became on the renewal of the war. At Waterloo his right arm was shot off, but he made good the deficiency to a certain extent by learning

to write without it. In 1816 he resumed his diplomatic position at Paris, and remained till 1819, when he became secretary to the Master-General of the Ordnance; in 1822 he accompanied the Duke of Wellington to the Congress of Verona; in 1825 he went with him to St. Petersburg as secretary of embassy, and in 1827, on the Duke being appointed commander-in-chief at the Horse Guards, he was made military secretary, and so remained until 1852. He then became Master-General of the Ordnance, Privy Councillor, and peer. R. was appointed to the command of the English troops operating in the Crimea when he was sixty-six years of age. His long administration of business in military offices during peace was, in the opinion of Kinglake, far from being a good preparation for the command of an army in the field, because the genius of war abhors uniformity and tramples upon forms and regulations. At Alma, Balaklava, Inkermann, and Sebastopol, R.'s courageous simplicity of mind was strongly revealed, but the disastrous repulse of his troops (June 18, 1855), together with grievous mismanagement in the commissariat, which entailed great losses among his men, prostrated him. He died June 28, 1855, of dysentery. His French colleague Saint-Arnaud talked of him as possessed 'd'une valeur antique,' but he did not possess the talent for swift initiative which is necessary in a position of the highest command. See Kinglake's *Invasion of the Crimea* (1863-77).

Ragman Roll, the name given to a record (preserved in the Tower of London) of the Scottish barons, landholders, clergy, and burgesses who did homage to Edward I. during his triumphal progress through Scotland in 1296 when John Baliol was de-throned. The original instruments of homage have almost entirely perished, but the R. R. enables us to understand how thoroughly the English king attained his purpose. The record is of great historical value. It is the only genuine statistical document of the time, and the names of the persons throw a flood of light on the ethnological conditions of the country. One point, for example, is made out quite clearly, viz., that at the close of the 13th c. the Gaelic element was still preponderant in Strathclyde—Fergus, Niel, Duncan, Donald, Dougal, Gilmore, and Malcolm being names of frequent occurrence, while 'Mac's' positively swarm. One might almost venture to affirm that 'English' was not yet the vernacular of districts like Ayrshire and Galloway. The work was published by the Bannatyne Club in 1834.

Ragout (Fr. *ragoûter*, 'to revive the appetite'), the French term for a stew of meat with vegetables and culinary herbs. It is essentially the same as the Irish stew.

Rags are the remains of textile substances after they have served the purposes for which they were originally fabricated. They are variously utilised, according to the nature and condition of the fibres of which they are made. Linen, cotton, hempen, and other R. of vegetable origin are principally employed as a raw material of the paper manufacture, the cellulose of which they are composed being perfectly fitted for that use. Linen R. are also reduced to the state of surgical lint, although that substance is now principally prepared from a specially woven loose linen texture. R. for papermaking are sorted into numerous qualities, the finest being white linen, and the lowest qualities are printed calicoes and heavy cottons such as moleskins, corduroys, &c. Woollen and worsted R. are used up in the Shoddy Manufacture (q. v.), and the fine fragments or dust of woollen and worsted cloth are dyed various colours and used for making flock papers for wall decorations.

Ragstone, a dark-grey siliceous sandstone which breaks with a rough or ragged fracture. It is much used in Kent as a building material.

Raguly (Fr. *ragulé*, 'fretted by rubbing'), in heraldry, an epithet applied to a notched or serrated line.

Ragusa (Slav. *Dubrovnik*, Turk. *Paprovnik*), a seaport of Austria, in Dalmatia, on a peninsula at the base and on the slopes of Mount Sergio, 103 miles S.E. of Spalato. With its old walls and towers, the town presents a medieval appearance, but it has also modern fortifications, with Fort Imperial on Mount Sergio and Fort St. Marco on the La Croma. It is well built, though many of the streets are steep, and most of them are narrow. The harbour immediately S. of R. only admits ships of 200 tons, but that of Gravosa, the real port N. of the peninsula and one mile distant, admits the largest vessels. Most of

the buildings, including the metropolitan church, were rebuilt after the great earthquake of 1667, but many splendid remains point to the former magnificence of the city, and two noble buildings have survived the overthrow—the Palace, a Renaissance structure, begun 1388, finished 1435; and the Dogana ('custom-house'), a Romanesque work, finished 1520. The trade of R. is chiefly in oil, soap, brandy, corn, rice, sugar, tobacco, and leather. It carries on also a large transit trade with Turkey by means of caravans, the annual imports of which are estimated at £98,000 and exports at £76,500. In 1871, 14,819 persons, forming 365 caravans with 9064 horses, visited the town. Pop. (1870) 8678. R. was founded in the middle of the 7th c. by the inhabitants of Old R. (the ancient *Epidaurus*) fleeing from the incursions of the Slavonians. It formed itself into an aristocratic republic under a count, afterwards styled a rector, and was until the 10th c. under the protection of the Slavonian princes of Narenta. Its inhabitants acquired great maritime power, and inflicted defeats on the Saracens. From 1260 till 1368 it had Venetian rectors, though it did not lose its independence. In the war between Genoa and Venice (1378-80) R. sided with the former, and sent a fleet to the battle of Chioggia. In 1414 it purchased peace from the conquering Ottomans by paying a tribute of 500 ducats, which in 1471 was raised to 8000 ducats. From this time the city paid a yearly tribute to the Porte, which gave it its powerful protection, without interfering with its internal affairs; consequently Ragusan traders enjoyed the peculiar good fortune of being safe from the ravages of the Barbary pirates. In 1806 Napoleon took possession of R., and in 1808 incorporated it with the province of Dalmatia, after an independent existence of more than 1000 years. In 1814 it fell to Austria.

Ragu'sa, a town in the S.E. of Sicily, on the right bank of the stream R. or Mauli, 31 miles W.S.W. of Syracuse. It consists of the two parts, R. Superiore and R. Inferiore, each with its own municipal government. In R. Superiore are several old churches which survived the earthquake of 1693, the finest of which, that of Santa Maria della Scala, has been spoilt by injudicious restoration. Many ruins in different parts, and the tombs in an ancient cemetery a mile to the W., point to the former grandeur of the city. R. manufactures linens, silks, and woollens, and has a considerable production of bricks and tiles. Pop. (1874) of R. Inferiore, 6826; of R. Superiore, 21,546. R. is probably the ancient *Hybla Heria*.

Rag'wort is the common name in England for the large and coarse species of the genus *Senecio* (q. v.), with yellow rayed flowers and lacinated leaves—more particularly to the widespread European species called *S. Jacobaea*. It is a troublesome perennial weed in pastures, &c., crowding out the desirable herbage, and is itself refused by stock. 'Grubbing' is the most effectual remedy. *S. aquaticus*, often met with in rough, damp, undrained pasture-ground, is the Marsh R. In Germany the name R. (*ragwurz*) is assigned to plants of the Orchis tribe, in conformity with its aphrodisiac application, as explained in the old herbals.

Rahel. See VARNHAGEN VON ENSE.

Rah'way, a city of New Jersey, U.S., 20 miles S.W. of New York, stands on a river of the same name, navigable for boats of from 4 to 8 feet draught. It has seventeen churches, two weekly newspapers, a printing-press manufactory, and thirty carriage factories. Pop. (1870) 6258.

Raig'urh, a hill fort in the district of Tannah, Bombay Presidency, British India, 65 miles S.E. of Bombay, and 52 N.W. of Sattara. It is situated among the N. Ghauts, and has been called, from its natural strength, the Gibraltar of India. In 1648 it fell into the hands of Sivaji (q. v.), the founder of the Mahratta power, who fixed his capital here. It surrendered to the British in 1818.

Raikes, Robert, the founder of Sunday-schools, was born at Gloucester in 1735. He was long editor and publisher of the *Gloucester Journal*, and during a life of philanthropy became intimately acquainted with the destitute and demoralised state of the children in and about his native town, then a great centre of the pin manufacture. In 1781 he engaged four teachers in dame-schools to give Sunday instruction in reading and the Church catechism, and in a short time the scheme met with a large share of success. A letter by R. in the *Gentleman's Magazine* for June

1784 led to the formation of numerous schools on the same model, and of a society under high patronage for the establishment of similar schools throughout the kingdom. This society expended £4000 to teachers in fourteen years. R. died April 5, 1811, and not long after his death the Sunday-school scheme was vastly extended by the teaching being made gratuitous. See Cornell's *Life of R. R.* (New York, 1864).

Rail, a term applied to various *Grallatorial* or Wading Birds. The *Kallus aquaticus* is the water-R.; the *R. Virginianus* the Virginian R.; the landrail being the familiar corncrake (*Crex pratensis*). The rails form the type of a family (*Kallidae*). The genus *Kallus* itself is distinguished by a markedly curved bill, with a long groove in which the nostrils are situated. The second and third quills are the longest, and the hind toe is short and slender. The water-R. attains a length of 12 inches. It is of a brown colour above, mottled with black. The throat, sides, breast, and under parts are grey, tinted with white and brown. The bird inhabits ponds and lakes. It is lithe and active, and is difficult to capture on account of the ease with which it makes its way through reeds and aquatic vegetation. The Virginian R. migrates to S. America in winter. It is of smaller size than the English water-R., and is of a black colour, striated with brown above and orange-brown below. Other American species of rails are the Great Red-Breasted R. (*R. elegans*), the Salt-water Marsh Hen (*R. crepitans*), and the Manque llen (*R. longirostris*).

Landrail.

Rails (Ger. *riegel*, Lat. *regula*), in architecture, the horizontal parts of a frame and panel, as opposed to the vertical pieces or stiles.

Railways and Railway System. The earliest attempts at railway construction in this country were made in the coal districts of Northumberland and Durham. They were originally limited to tramways of flagstone flanked by parallel rows of planking. So long ago as 1630 something of the kind was used by a Mr. Beaumont, manager of collieries near Newcastle-on-Tyne, and in the beginning of the 18th c. the practice was extensively adopted. Improvements were gradually but slowly made; slips of iron were added to increase the durability of the rails, and subsequently flanges to prevent the waggons from running off. The first considerable iron railway was laid down at Colebrookdale, in Shropshire, in 1770. The upper rails were made of cast-iron 5 feet long, 4 inches wide, and 1½ inches thick, with raised rim, to keep the carriage wheels on the track, and with holes through which they were spiked to the lower wooden rails. The iron railways, or tramways, as they were called, which followed this, were constructed on a like principle, although the rails were broader and thicker. Upright flanges were used in the railway on the Duke of Norfolk's collieries near Sheffield in 1776. Jessop introduced smooth rails at Loughborough in 1789, flanges being placed on the carriage wheels. Wrought-iron rails were introduced in 1808, and improved machinery for rolling them followed. The real foundation of the railway system was, however, the introduction of steam. In 1759 Dr. Robison had suggested to Watt the construction of a steam-carriage, and the latter patented an invention of the kind in 1784, a working model of which was made by Murdoch, his assistant. Cugnot, a native of Lorraine, made a model locomotive for dragging cannon in 1763, and a full-sized engine in 1769, which, loaded with twelve persons, travelled at the rate of 2½ miles an hour. Oliver Evans, an American, invented a road steam-carriage in 1772. A self-acting locomotive was patented by Richard Trevithick in 1802, and exhibited in a field near Euston Square. A second engine, by the same maker, was used to draw waggons at Merthyr Tydvil in 1804, but only worked well with light loads on level surfaces or moderate grades, the extent of its power being to draw 10 tons of iron at the rate of about 5 miles an hour. For a number of years an imaginary obstacle de-

layed railway progress, the opinion being prevalent that the adhesion between the wheels of a loaded engine and the rails was not sufficient for the purpose of traction, but that the wheels would slip round upon the rails without making progress. Cogged wheels were therefore used, and numerous patents were taken out for racks, chains, &c. Blenkinsopp's engines from Middleton Collieries to Leeds ran on a racked or tooth-rail laid on one side of the road, dragging thirty coal waggons at the rate of $3\frac{1}{2}$ miles an hour. The fictitious difficulty was not finally dissipated until 1812, when smooth wheels were proved by Mr. Blackkett at Wylam to be quite efficient in ordinary cases if an adequate proportion of weight were made to press upon them. The subsequent rapid progress of the locomotive was, according to Robert Stephenson, 'not due to one man, but to the efforts of a nation of mechanical engineers.' The greater share of the honour is, however, undoubtedly due to the father of this modest speaker and to himself. George Stephenson's first 'Travelling Engine,' constructed in 1813 at Killingworth Colliery, where he was engine-wright, drew 30 tons weight at 4 miles an hour. An engine made by him two years later contained the germ of all that has since been effected, and is the type of the present locomotive engine. A locomotive on the Killingworth model was made for the Duke of Portland for use on a tramroad from Kilmarnock to Troon in 1817, but frequent breakages of the cast-iron rails caused its discontinuance. The Hetton Railway, from Hetton Colliery, Durham, to the coast, was constructed under Stephenson's direction in 1819, and was opened on 18th November 1822, on which day five of Stephenson's locomotives each travelled at the rate of 4 miles an hour dragging seventeen waggons weighing about 64 tons.

The turning point in the history of railway enterprise was the construction of the Stockton and Darlington line. Previous to this about twenty Acts had been passed for the construction of railways, commencing with the Wandsworth and Croydon line, projected in 1801 and completed in 1805, but the Stockton and Darlington was the first railway which carried passengers, and on which the locomotive had an extended trial. The scheme was set on foot by Edward Pease and a number of other members of the Society of Friends, on which account the railway obtained the designation of 'The Quakers' Line.' An Act for the purpose received the royal assent on 19th April 1821. Stephenson resurveyed the ground afterwards, and although the original proposal was to use horses, he impressed Pease with a high opinion of his locomotive. A second Act was obtained in 1823. An engine factory was established by Stephenson, Pease, and others at Newcastle in 1823, where many of the most celebrated engineers of Europe, America, and India have since been educated. The line was opened 27th September 1825, the locomotives dragging 90 tons, including 600 passengers, at a rate of 12 miles an hour. Among the oldest advocates of a national system of railways were R. L. Edgworth, who described in *Nicholson's Journal of the Arts* in 1802 a project he had formed many years before for laying iron rails on the main roads of England; Dr. James Anderson, who made a similar recommendation in 1800; and Thomas Gray of Leeds, who sketched a most able and comprehensive plan in his *Observations on a General Iron Railway* (1820). It is much to the credit of the *Scotsman* that it was the first newspaper in the kingdom to give railways hearty support, a series of remarkable and far-seeing papers appearing in its columns in 1824 from the pen of the editor, Mr. Charles MacLaren, full of confident anticipation. They were extensively circulated in Britain, America, and the Continent, and did much to press forward the movement. The second railway in Great Britain to carry passengers and use locomotives was that from Monkland to Kirkintilloch, Scotland, opened in September 1826. A year or two later came the Ballochney and the Canterbury and Whitstable Railways. But the line which finally broke the neck of the opposition, and ensured the triumph of the innovation, was the Liverpool and Manchester Railway. The marvellous increase in business between these two great towns had for years quite outstripped the tardy efforts of the canal companies, and in 1821 a tramroad was projected between them. William James, of West Bromwich, a surveyor, suggested the formation of a railway in 1822, but his plan was not taken up. A scheme devised by Joseph Sandars in 1824 was more successful. Stephenson surveyed the ground in that year, meeting with

the greatest difficulties from the canal proprietors and landowners, who organised a determined opposition. In all England, only one engineer, James Walker, was prepared to support Stephenson's evidence before the House of Commons as to the speed of the locomotive. A writer in the *Quarterly Review*, while supporting the scheme, hoped Parliament would limit speed to 8 or 9 miles an hour, that being, in his opinion, as high as could be ventured on with safety. The Bill was defeated in 1825, but passed in 1826. For traction a multitude of schemes were suggested—water-power, hydrogen, carbonic acid gas, &c. Gray urged the use of a greased road, and Vignolles and Ericsson a central friction rail. Stephenson advocated smooth rails and locomotive engines. Two consulting engineers were selected to report to the Directors, and they recommended fixed engines at stages of $1\frac{1}{2}$ miles each to work the trains forward. The bewildered Directors inclined to their own engineer, and offered a prize of £500 for the best locomotive engine, three of the leading conditions being that it was to consume its own smoke, to draw 20 tons weight at 10 miles an hour, and that its price should not exceed £550. Robert Stephenson's engine *Rocket* more than fulfilled all the conditions, and on the trial day not only gained the prize over three other competitors, but decided the Directors in favour of the locomotive. The line, notwithstanding great obstacles, was successfully constructed—a road over Chat Moss, a bog of 12 square miles, being a triumph of engineering—and the railway was opened for traffic on September 15, 1825. Its undoubted success completely proved the practicability of railways, and the public spirit and enterprise of the country were henceforth abundantly forthcoming for the extension of the system. Railways were laid down between all the manufacturing centres of the N., and were projected from the metropolis in all directions. Landowners, who were at first intensely hostile, came to see the effect of a railway was not to diminish but to increase the value of their property. In ten years 2500 miles of railway, almost all with double lines, had been laid down at a cost of £60,000,000. Space forbids any account of the gigantic growth of the system, and the enormous advantages which have accrued from it are so transparent that it is unnecessary to dilate upon them. Railways acted like swift and navigable rivers, stimulated production all over the country by creating markets for produce, vastly economised time, labour, and money, offered a rapid and commodious means of travel to any portion of the kingdom to all sections of the community, assisted the diffusion of knowledge, created large towns, and strengthened alike national ties and international interests. Over-competition and reckless speculation was often indulged in; many private individuals, particularly during the Railway Mania of 1844-46, were ruined, yet, after all, the monetary value of railways to the nation far exceeds even the wasteful amount which has been spent upon them. (For present statistics of British railways, see end.) England's example was speedily followed by most European countries, many lines being constructed largely by British capital and British engineers. The first railway in France, from Paris to St. Germain, was finished in 1835. In the course of thirty years the entire mileage amounted to 8500, and one half more has since been completed. America, however, with true Anglo-Saxon enterprise, took the field before the nations of the Continent. A railway, part of the Baltimore and Ohio line, was opened for passengers on 31st December 1829, locomotive power having previously been employed on a line from the Delaware and Hudson Canal to Honesdale. The railway mileage in the United States was 2818 in 1840, 30,635 in 1860, while in 1876 it reached the astonishing total of 77,457, or three times the circumference of the globe. In 1871 alone 7660 miles were opened. In 1848 the first grants of land to a railway (the Mobile and Ohio) were made by Congress, and this step led to most beneficial results. The increase of wealth and population west of the Rocky Mountains, owing to the discovery of gold in California and other causes, induced Congress to authorise the Pacific Railroad in 1862. The railway crosses nine separate mountain ranges, and attains an altitude at the eastern rim of the Great Salt Lake basin of 7458 feet. The railway system has been developed with great energy in Canada, Australia, the British colonies, and in India. In 1869 the Indian Government, which had previously guaranteed interest to shareholders and reserved power to control proceedings, decided on carrying out all extensions by direct state agency.

The following table, amended from the *Statesman's Year Book* for 1878, shows the mileage of the railways of the world on 31st December 1855 and 31st December 1876:—

States.	Length open for Traffic in English Miles.		One Mile of Railway to sq. mile of area in 1876.
	Dec. 31, 1855.	Dec. 31, 1876.	
EUROPE	21,140	92,116	41
Belgium	828	2,105	5
Great Britain	8,336	16,872	7
Switzerland	129	1,478	10
Germany	4,863	17,131	11
Denmark	18	853	12
France	3,436	12,723	13
Netherlands	195	1,223	17
Austro-Hungary	1,758	10,138	20
Italy	566	4,035	22
Spain	275	3,710	50
Sweden	23	2,346	54
Portugal	22	644	56
Roumania	766	59
Russia in Europe	649	12,350	148
Turkey	965	150
Norway	42	504	242
Greece	7	2,848
AMERICA	20,042	88,540	181
United States	19,247	77,457	46
Peru	52	2,039	248
Dominion of Canada	6,412	509
AFRICA	1,847	6,337
ASIA	156	8,076	2,470
British India	156	6,938	129
AUSTRALASIA	2,688	2,050
Victoria	618	155
New Zealand	575	190
Tasmania	170	562
New South Wales	445	784

In 1877 about 5000 miles of railroad were in formation throughout the British Empire. A railway through the entire dominion of Canada, from the Atlantic to the Pacific, is at present being constructed, which will, when completed, establish an actual as well as political union between all the provinces of that vast colony. The expense is estimated at £32,000,000, and the British Government has contributed to this a guaranteed loan of £2,500,000. Among the mighty projects of the future may be mentioned a railway from Russia through Siberia with a branch to Tashkend, though it is probable that the financial strain of the late war will postpone its construction indefinitely. Through communication from England to India may be considered only a question of time. According to Mr. Simon M'Bair's volume on *To India by Rail* (1876), 2209 miles of such a line are at present in existence, leaving 3660 miles to be constructed, at an estimated cost of £32,000,000. A Committee, of the House of Commons considered in 1872, but did not give its support to, a proposal for a railway *via* the Euphrates valley.

Railway Legislation and Management.—The policy of Governments differs widely on the subject of railway management. In most Continental countries everything connected with railroads is organised on a systematic and uniform plan, and in some countries, such as Belgium and Germany, the state is a great railway proprietor. In France and elsewhere the Government determines the localities for which railway communication is to be provided, lays out the line, regulates the number of trains, fixes tariffs, and controls to the most minute details the general administration of the system. In England and America, on the other hand, everything is left to experience, and no fixed principle or plan exists. Government solely authorises the construction of a line and defines the powers of the company which is to work it. The tendency everywhere has been towards amalgamation and monopoly, the large companies gradually swallowing the smaller ones. Almost the whole railway system of France is in the hands of six companies, viz., the Paris, Lyon, and Mediterranean, the Paris and Orleans, and the Northern, Western, Southern, and Eastern. In this country half the total mileage is owned by the London and North-Western, the North-Eastern, the Great Northern, the Great Western, the Midland, the Great Eastern, the Lancashire and Yorkshire, the North British and the Caledonian Companies. The pur-

chase of British railways by the state has been lately urged by an influential party. The Government had power by an Act passed in 1844 to purchase all lines after they had been in existence twenty-five years after that date, but a Committee of Parliament reported in 1872 that the terms of the Act were at that time impracticable. There are many obstacles in the way of purchase. The enormous expense would probably be much increased by speculative movements, and would more than double the National Debt, the temptation to political favour would be great, a dangerous power would be at the command of the party in office, while the right of the state to make every subject a compulsory partner in so great an undertaking may be questioned. On the other hand, much expense might be saved, particularly in preparatory charges, the construction of useless lines might be avoided, and a system of more uniform or at least cheaper rates to all places in the kingdom might be adopted. At present railways in the United Kingdom are started by private individuals, who form a company. The 'Standing Orders' of Parliament afford opportunity to petitioners in favour of and against the proposed scheme to state their case before that tribunal. The examiners of private bills see that the standing orders have been complied with previous to submission of the Act to Parliament. After the second reading of the bill in the House of Commons, which is tantamount to an approval of it in principle, it is referred to a Select Committee, which hears both sides, and reports on the evidence. If the bill passes the Commons, it goes through a similar ordeal in the Lords. Acts of Parliament sometimes cost enormous sums. That for the Great Western cost £88,000, and that for the Brighton line even more. Railway shares are first in the form of scrip, deposits being paid by those to whom they are allotted, to meet the preliminary and parliamentary expenses. The balance is paid on the passing of the Act by calls, and the company is authorised to borrow one-third of its stock by debentures. *Debenture stock* has a perpetual guaranteed dividend. *Preference stock*, of which there are many varieties, is so called from its being preferred to ordinary stock in the payment of dividends. The liability of shareholders is limited to the amount of their shares. The shareholders elect the Directors from among their own numbers, and meet personally or by proxy, usually every half year, when the Directors' report is read, and the current dividend declared. The secretary and other officers are elected by the Directors.

The *Construction* of railways is executed by contracts, usually let out to public or private competition. The surveyors of early railways followed as closely as possible the natural declivities of the ground, and afterwards the practice was more largely introduced of moderating these declivities by embankments, arches across valleys, cuttings or tunnelling through hills, &c. *Tunnels* and *viaducts* being very expensive, are never used when it is possible to dig *cuttings* and build *embankments*. The material, earth, &c., taken from cuttings generally goes to make embankments, and the engineer has to arrange his plans to make the two operations fit as well as possible. The railway and earthworks require careful draining, and it is much better that this should be done thoroughly at first. As regards *gradients*, the tendency has been to increase. On the oldest lines grades of 30 or 40 feet to the mile were considered heavy, but these have since been much exceeded. In England grades of 100 feet are not uncommon, there are several of 150 feet and even more, one of the greatest (196 feet) being near Sheffield. In Switzerland, where the grades are very severe, as on the slope of the Righi, central cogged rails are used. It is now asserted that grades of 370 feet are workable by locomotives. *Curves*, when adopted in railway lines, are with few exceptions over $\frac{1}{4}$ th of a mile in radius, though many are under half a mile. The Government formerly, in both France and England, fixed a minimum radius for railway curves. They should be avoided at portions of a line where great speed is desirable. Mechanical contrivances affecting the wheels or rails are used where the curves are narrow in radius in order to prevent the train running off the line. After the level road has been constructed over bogs, hills, or ravines, a thousand minute details require the engineer's attention. Each rail with its fastenings must be completed and the whole road carefully ballasted up to the proper level. The material in which the railway sleepers are imbedded consists usually of broken stone or coal, gravel, cinders, or similar substances, and is technically called *ballast*. The ballast promotes drainage by its porosity,

resists the sinking of the sleepers, and gives elasticity to the line. It is usually about 2 feet in thickness, one foot being below and one foot around and above the sleepers. The best material for sleepers is oak, which is, however, expensive. Larch and timber from the Baltic are most generally used in this country, and hemlock and chestnut trees in the United States. The trees, about 10 inches in diameter, are split through the middle, and the sleepers thus formed, which must be straight and uniform in size, are laid down about 3 feet apart from one another. In their natural state they last six or seven years, but the process of creosoting renders them much more durable. In India, where wood is expensive, rectangular blocks of cast iron have been used as sleepers.

Rails.—For many years the iron used for rails was inferior, but has lately much improved in quality, and since the year 1837 steel rails have been largely introduced. Steel rails cost about one-half more than iron rails, but last enormously longer. In Great Britain and Europe the usual form of rail is the double-headed, which when worn on one edge is reversible. It requires a cast-iron chair on every sleeper in which it is fixed. In America the base of the rail is about 4 inches wide, and chairs are dispensed with. Rails are about 24 feet long in this country, and in America 30 feet is usual. 85 to 100 lbs. per yard was formerly considered the best weight for rails, but now a weight of 35 lbs. for light rails and 60 for heavy rails is thought sufficient. The joints of the rails are secured by fish-plates and fastened by screw bolts. Switches or points and crossing by turntables and traversing platforms are used for the passage of a train from one set of rails to another.

All railway lines are divided into districts, to which gangs of platelayers are attached. Their duty is to inspect the rails, points, and signals in their portion of the road every twelve hours, and to keep them in perfect repair. For the purpose of signals, again, a railway is divided into blocks, each commanded by a signal cabin, in any one of which there must be only one train at a time on each line of rails. One signal box frequently commands several separate lines of rails, and the duties of the signalman then require his most unceasing vigilance.

Gauge.—In the first railways constructed George Stephenson adopted a gauge of 4 feet 8½ inches, that being the gauge of the common vehicles of the country at the time. Brunel and other engineers subsequently recommended a much wider gauge, but in 1846 the gauge was fixed by Parliament at Stephenson's dimensions for all railways in the United Kingdom except the Great Western. The latter railway afterwards adopted 4 feet 8½ inches also, and the practice thus became universal. The early lines on the United States used the British gauge, but in the S. and W. from 5 feet to 6 feet was afterwards common. Experience has not been in favour of broad gauges, and on a memorable occasion the Ohio and Mississippi Railway changed their gauge from 6 feet to 4 feet 9 inches, by moving a line of rails along their entire route on a single Sunday night. Lines on narrower gauges have lately been sanctioned in Russia and adopted in Canada, some parts of Sweden, and Switzerland. The Indian Government decided on 5 feet 6 inches in 1851, but adopted 3 feet 3 inches in 1873 for the sake of economy in the construction of the Punjab, Scinde, and other large railways. With a narrow gauge expense is diminished, and the ratio of dead to useful weight in a train is lessened.

The cost of railway construction in Great Britain has been much greater than in America, the aggregate expenses connected with the formation of all the lines in the two countries being about equal, although the mileage of railways in the United States is five times that of this country. This is accounted for partly by the enormous preliminary expenses which have been paid by British railway companies. To construct the railways of the United Kingdom up to the end of the year 1875 (see D. Kinnear Clark's contribution to *British Manufacturing Industries*), cost £630,223,494, or £37,833 per mile, only about two-thirds of which was actually expended in works, the remainder being paid chiefly in law expenses and compensation to land-owners. The sums paid as 'land damage' used to be most exorbitant, and even now it is probably double the real value of the land, so general is the prejudice in favour of private as opposed to public interests. Unfavourable physical features have also increased the expense of English lines. But the cheapness of American railways is more apparent than real. They

are built at the lowest possible estimates, and light rails, narrow banks, and wooden or trestle bridges are extensively used. The result is that the subsequent expense in maintenance and repairs is much greater in America than in Great Britain. In England one ton of bituminous coal suffices for about 75 miles of journey, against 45 in America.

Tunnels, Viaducts, Bridges, &c.—(1) **Tunnels.**—One of George Stephenson's most splendid efforts was the Kilsby Tunnel, on the London and Birmingham line, which is 2398 yards long, and cost £300,000. The Thames Tunnel, now used, though not originally constructed for a railway, is also a wonderful work, and the Underground Railway in London, which cost on an average £700,000, is also a splendid achievement. The Watford Tunnel, 1 mile long, cost £140,000. The Woodhead Tunnel (3 miles 60 feet) is the longest tunnel in Great Britain. Tunnels have, however, been constructed on a much grander scale elsewhere. The Mont Cenis Tunnel, about 8 miles in length, uniting the railways of France with those of Italy, was constructed in 1857-70, and cost £3,000,000. The St. Gothard Tunnel, now being carried through, and which will probably be completed in 1879, is on a larger scale still. It is designed to connect the Swiss railways with those of Northern Italy. But a gigantic scheme has in the last few years been mooted, before which even these great efforts pale, viz., the projected Channel Tunnel, from St. Margaret's Bay, South Foreland, to a point between Calais and Sangatte, a length of 22 miles, requiring, with approaches, 31 miles of railway. A rival proposal has been made to lay a pair of huge tubes from Dover to Cape Grisnez. Either scheme would practically annex our railway system to the whole of the railways of the Continent. (2) **Bridges.**—The High Level Bridge at Newcastle, one of the most picturesque and imposing of railway structures, was designed by Stephenson and opened in 1845. The Britannia Bridge over the Menai Straits, opened 5th March 1850, is 1841 feet long, and cost £600,000. In S. Devonshire there are 5 miles of bridges and viaducts designed by Brunel on a gigantic scale. Some of the railway approaches to London are constructed for several miles on arched viaducts of brick. The Tay Railway Bridge, opened 31st May 1878, is at present the longest railway bridge in the world (10,612 feet, in 85 spans, 11 being of 245 feet each). It was designed by T. Bouch, and cost £350,000. The Victoria Bridge, which crosses the St. Lawrence near Montreal, is 7000 feet long, but the Royal Albert Bridge, designed by Mr. Legge to cross the same river, will be 15,500 feet long. The E. River Bridge between Brooklyn and New York, and the St. Louis Bridge, are two of the first works of the kind in the United States. Elevated rack railways, such as that from the Battery to 30th Street, New York, are features in the streets of some American cities. The combined road and railway bridge over the Rhine at Cologne cost £600,000. Hollandsch Diep, near Maerdijk, Holland, is a remarkable work 7 furlongs long. It cost £460,000. The Sommerung Railway, connecting Vienna and Trieste, abounds in extraordinary works, steep gradients, vast tunnels and viaducts.

Rolling Stock.—**Locomotives.**—In recent years locomotives have increased in size. Six-wheeled engines are used in this country, and eight and even ten wheels in America and some parts of Germany. The weight of a modern engine ranges from 6 to 50 tons, including the tender, and the load from 50 to 500 tons. The usual weight is 20 to 25 tons. A first-class engine to travel fifty miles an hour will weigh 30 tons, and cost £3000. **Carriages.**—Passenger-carriages are of three kinds, first, second, and third class on all British railways except the Midland, where only two classes are used. On most lines all classes of passenger carriages have recently been made more comfortable. The long train-like carriage is an American invention. The new carriages of the Midland line cost from £500 to £600 each. They rest on 6-wheeled bogies, and each has four first-class and four third-class compartments and a luggage box. Recently sleeping accommodation has been provided for on the long-journey trains in this country by the use of Pullman cars.

Speed.—The average speed of express trains in England is over 40 mile an hour, and at some places exceeds a mile a minute. The journey from London to Exeter by the Great Western Railway, 193 miles, is accomplished in 4½ hours, and from London to Edinburgh by the Great Northern and North British Railways in 9 hours. The latter, not taking stoppages into account, gives an average continuous speed along the whole route of 44 miles

an hour, it being greatly more at various portions. Continental and American railways are slower. The fastest train in France, from Calais to Paris, travels at 37 miles an hour. From Paris to Marseilles (537 miles) takes 15½ hours, the average per hour being 34 miles. The highest speed in Belgium and Holland is about 33 miles. In Germany and Switzerland few lines much exceed 20 miles. From Berlin to St. Petersburg (1028 miles) is traversed in 46 hours, the average being 22½ miles. In America 30 miles is considered fast.

Passengers and Fares.—The total number of passengers who travelled by railway in the United Kingdom during the year ending 31st December 1876, excluding 394,427 season-ticket holders, was as follows:—

1st Class,	44,859,066
2d Class,	66,478,195
3d Class,	426,950,034

538,287,295

The following statement of the proportion of the total passengers carried in the three classes in 1855 and 1876 shows an increasing tendency on the part of the public to travel third-class:—

	1857	1876
1st Class,	13.4	8.3
2d Class,	30.4	12.4
3d Class,	56.2	79.3

Fares, average 2½d. per mile for first class, 1½d. second, and 1d. or 1½d. third. When return tickets are granted, the average charge for the double journey is about a fare and a half. Special excursion trains frequently run at much lower rates. In the booking-office attached to the stations the tickets are arranged in long upright tubes in reversed numerical order. Only one ticket for a particular place and class can be drawn out at a time, and the last remaining ticket in the tube always shows the number sold. A large Clearing-House, on the banker's principle, is established near Euston Station, London, where all the accounts for the through traffic is settled. The money received at all stations for joint tickets is paid into the Clearing-House, and the proper proportions are thence every month handed to the various companies according to a mileage scale. The regulations as to luggage, &c., are looser in England than on the Continent, on account of the high pressure demanded. A general improvement is, however, observable in railway station accommodation, and the practice of having hotels attached to the termini has been found a great convenience. The traffic managers, locomotive superintendents, and station-masters are responsible for the organisation and smooth working of all passenger and goods trains. The difficulties of the traffic manager may be estimated by considering that Bradshaw's Guide gives the time of running of passenger-trains only, and that he is in addition responsible for all the mineral and goods trains, which must not disturb the ordinary traffic.

Accidents.—In the year 1876 the following casualties occurred on railway lines in the United Kingdom:—

	Killed.	Injured.
Passengers —		
1. From causes beyond their own control	38	1279
2. From misconduct or want of caution	101	604
Railway Servants —		
1. From causes beyond their own control	43	384
2. From misconduct or want of caution	630	2216
3. Persons passing over level crossings, trespassers and suicides	433	241
Total	1245	4724

Taking a series of years, the causes of railway accidents have been classified by Mr. J. Bramwell as follows:—

Collisions of various kinds	58.7 per cent
Trains going on wrong lines	12.0 "
Leaving the rails	9.2 "
Defects in rolling-stock	9.2 "
On inclines	4.6 "
Entering stations at too high speed	1.8 "
Miscellaneous	4.5 "

100.0 per cent.

During the year 1876, the total number of safe journeys accomplished bore the proportion of 4,500,000 to one fatal accident, or excluding the fatal accidents arising from the passengers' own fault, the proportion of 14,000,000 to 1. Probably the most perfect arrangements will never wholly prevent accidents.

Statistics.—The following additional statistics of the railways of the United Kingdom, as at 31st Dec. 1876, are interesting:—

	Authorised Capital of Railways.	Gross Receipts during year.	Working Expenses during year.
England & Wales	£611,412,535	£52,476,319	£28,466,366
Scotland	92,725,357	6,965,091	3,597,993
Ireland	37,664,635	2,774,365	1,471,180
United Kingdom	£741,802,527	£62,215,775	£33,535,539

£549,095,705 of the authorised capital was by shares and £192,706,822 by loans. The paid-up stock and share capital was £490,916,875. The passenger traffic and mails gave 42.05 per cent. of the gross receipts or £26,163,551, and the goods traffic 54.25 per cent. or £33,754,317. The value of the passenger and goods receipts was about £3551 per mile, and 5s. 6½d. per train mile. The total capital received by railway companies in the United Kingdom including loans and debenture stock has been at the rate of £39,012 per mile of railway constructed up to the end of 1876. Railway dividends paid in 1876 varied from 1 to 13 per cent., the great bulk lying between 3 and 8. The total mileage open on 31st December 1876 was

England and Wales	11,989
Scotland	2,726
Ireland	2,157

Total—United Kingdom 16,872.

The Great Western Railway has the greatest mileage (2059 miles), the London and North-Western carried the greatest number of passengers in 1876 or 46,746,332, and the North-Eastern Railway the heaviest weight of goods or 34,343,695 tons.

References.—The third volume of Smiles' *Lives of the Engineers* (1862) contains a good history of the early English railways. See also a *Book about Travelling, Past and Present*, by T. A. Croall (London and Edinburgh, 1877); Wood *On Railroads*; Simm's *Public Works of Great Britain*; Pambour, *The Locomotive Engine*; Clark *On Railway Machinery*; *Reports of Commissioners on Gauges*; and the annual Reports of the Railway Commissioners. Bradshaw's *General and Steam Navigation Guide*, published monthly, is a most admirable and comprehensive collection of time-tables. Poor's *Railway Manual* is a standard authority on American railways.

Laws Affecting R.—By 24 and 25 Vict. c. 97 any malicious injury to a railway or malicious obstruction of the line is a felony, subjecting the offender to penal servitude, possibly for life.

Liabilities.—Every railway is required to forward goods and passengers without unreasonable delay. The company must provide reasonable accommodation in their trains, but they are not bound to accommodate an extraordinary number of passengers. It is liable for neglect or default in the carriage of goods to a limited amount. Extra value may be declared and paid for.

Raimon'di, Marc Antonio, the most famous of the early Italian engravers, was born at Bologna about 1488. Originally apprenticed to a goldsmith, he studied design and engraving in *niello* under Francia, and his first copperplate is a reproduction in 1505 of the 'Pyramus and Thisbe' of the famous Bolognese. Vasari says that R. adopted the profession of an engraver after seeing some of Dürer's woodcut prints. When he went to Venice in 1506, he copied with the minutest accuracy the entire series of Dürer's 'Passion of our Lord' and 'Life of the Virgin.' To one of these he affixed the monogram of Dürer, and the prints sold as originals. Dürer was so enraged, according to Vasari, that he hastened to Venice and procured from the senate an order restricting the future use of his monogram or mark. In 1510 R. removed to Rome, where among his earliest works were Raphael's 'Lucretia' and 'Judgment of Paris.' So pleased was the great master with the execution of these that he permanently secured R.'s services. For the next ten years R. devoted himself exclusively to engraving Raphael's pictures, aided by a body of pupils, among the best of whom were Marco da Ravenna and Agostino Veneziano. In this way R. founded what is called the Roman school of engraving. After Raphael's death he was mainly engaged on the designs of Giulio Romano; and as the engraver of that artist's indecent illustrations of Aretino's sonnets he was

imprisoned by Clement VII. Released on the intercession of Cardinal de Medici, he acquired the favour of the Pope by engraving Bandiell's 'Martyrdom of San Lorenzo;' but the sack of Rome in 1527 reduced him to poverty. He then retired to Bologna, where he appears to have resided till his death, the date of which is uncertain, some authorities assigning it to 1539, others to 1546. One of the earliest, he is also one of the greatest of all engravers. His treatment of Raphael's designs has never been equalled for precision and delicacy of touch, subtlety, and range of tint, and faithful preservation of the painter's feeling. From the first his works, of which there are over 600, were in great request, and hence the plates soon got worn, and only early impressions are worthy of his name. At Mr. Johnson's sale in London, in 1860, a 'Judgment of Paris' brought £320. Fine collections of R. are in the print-room of the British Museum and in the Louvre.

Rain is the result of the condensation of the water-vapour ever present in the air into drops, which descend by their own weight to the surface of the earth. Even when there is not a cloud in the sky there is always a considerable quantity of moisture in our atmosphere, and this moisture is a most important element in the modifications of climate. The quantity which the air can retain depends upon the temperature—the higher the temperature the greater the quantity; and when the maximum quantity for any temperature is present, the air is said to be saturated. Saturation must always precede precipitation. The air, however, is not always saturated. As a rule, the moisture present could be held in suspension by the same mass of air at a lower temperature; and the temperature, for which the air would be saturated in the given circumstances, is called the dew-point. The determination of this critical temperature by the ordinary methods of Hygrometry (q. v.) gives the necessary datum for finding the absolute humidity of the air, *i.e.*, the quantity of water-vapour in unit mass of air. The ratio of the actual quantity present to the maximum quantity which the air at its present temperature could hold is called the relative humidity, or simply the humidity. It is the humidity which indicates the dryness or wetness of the air. If it is nearly unity, the air is nearly saturated, and is therefore wet; and the smaller the fraction which expresses the humidity, the drier is the air. Any cause which lowers the temperature of the air below the dew-point is sufficient to cause deposition of moisture, which appears as dew, mist, R., snow, or hail, according to the circumstances under which the cooling has taken place. On a clear still night after a hot summer day, the conditions are most favourable for the deposition of dew. The surface of the earth radiates rapidly the heat which it had absorbed during the day, and soon cools below the temperature of saturation of the contiguous air, which, reduced also in temperature, is no longer able to retain the moisture it formerly held, but deposits it as dew on the cool surface. Here there is generally no cloud formed, since the condensation takes place not in the body of the air, but only along the thin stratum in immediate contact with the colder earth. Sometimes, however, and especially if the air is nearly saturated, a broader stratum is reduced in temperature, and there results the well-known evening haze, which gives to the setting sun or rising moon a characteristic ruddiness. This haze differs only in degree from the thick fogs which frequently envelop our islands. A slight diminution in temperature of a mass of nearly saturated air is sufficient to cause the vapour present to condense into minute drops, which make up what we understand usually by a cloud. Mist or fog is simply a cloud formed close to the surface of the earth. The most usual causes which effect this condensation are the cooling of the air by its own expansion, the intermingling of two masses of air at different temperatures, and the impact of the moisture-laden air against a cold surface. When a stream of heated air ascends, it loses heat in two ways—by radiation and by expansion—and thus it gradually cools until it can no longer hold the water-vapour present as vapour. Condensation takes place, and clouds are formed in the high strata of the air—clouds which by their own weight are always descending. Should these in their descent pass into a sufficiently dry mass of air, they will gradually evaporate again and disappear. They are not R.-clouds. R.-clouds are usually the result of the indraught of a warm saturated current of air into a colder region, or of a cold current into a warmer saturated region. If the lowering of the temperature is not

sufficient to bring it below the saturation point, no condensation can take place and no rain will fall. A current of air which flows from a more humid to a less humid region must necessarily feel *wet*, even though it be unaccompanied by precipitation, and a wind from a less humid to a more humid region is *dry*. The trade-winds are therefore dry, while the heavy rains in the intermediate region of calms are the result of the rapid cooling of the ascending masses of air which have been saturated with moisture through the action of the sun's tropical heat. Clouds are thus formed, and these, cooling continually by radiation from their upper surface, descend gradually towards the earth. The drops, at first small, grow in size, the larger ones growing at the expense of the smaller, until their weight, ultimately overcoming the viscosity of the air, precipitates them as R. During evaporation heat is absorbed, while during condensation it is evolved. Hence a cloud when forming is at a considerably high temperature—a fact which may be readily observed as a sudden mist is settling down. The cause of R., then, is a more or less sudden alteration in temperature. This change is generally accompanied by wind, and hence wind and R. are usually, and in some regions invariably, the accompaniments of each other. Forests have a great influence on the rainfall of a country. They seem to attract the R., and thus are their own preservers, since R. in turn encourages vegetation. As a country is cleared of its wood, its climate becomes drier, a phenomenon which has been extremely well marked in Queensland and other parts of Australia. The relation of rainfall to seasons is most marked in the tropics. Winter is the dry season, summer the wet; and as a rule the air is more humid in summer than in winter all over the globe. Everywhere, however, even in the tropics, the configuration of the land has a great influence upon the rainfall. The direction in which to look for the explanation of this is indicated by the consideration that the grand source from which the atmosphere draws its vapour is the ocean. If the prevalent winds set from the ocean towards the land, the likelihood is that that region will be wetter than if the prevalent winds set from inland. The moisture-laden air, again, after crossing a considerable tract of country, gradually loses its vapour, especially if the country be mountainous. Mountains and mountain-ranges powerfully influence the climate of the contiguous country, robbing the air of its moisture as the current speeds past. Thus, during the S.W. monsoon of India, there is no rain on the E. coast, but there is a copious precipitation on the W. coast. The W. of Europe, exposed to the Atlantic, has generally a wetter climate than the E. There are also certain parts of the earth where R. never falls. The best known of these are the Sahara in Africa, the Desert of Gobi in Asia, the basins of the Columbia and Colorado in N. America, and the coast of Peru in S. America. In the last case, the Andes acts as a complete barrier to the clouds which are borne from the Atlantic, and which pour forth their stores of water upon the eastern slopes, feeding the tributaries of the Orinoco and Amazon. The greatest rainfall on the globe occurs at the Khasi Hills (q. v.) in Assam, where 600 inches fall in a year.

Rain-Bird (*Saurothera vetula*), a species of *Scansorial* birds allied to the cuckoos, inhabiting S. America and the W. Indies. It is also known by the name 'Tom Fool,' on account of the carelessness and prying curiosity with which it will approach any new or unusual object. The wings are weak. Its colour is a brownish grey above and a yellowish brown below, the tail being varied with white and black. This bird belongs to a small group of the *Cuculidae*, named the 'Ground Cuckoos.'

Rain/bow, the well-known luminous arch which is frequently seen stretching across the heavens after or during a shower of rain. The circumstances under which such a phenomenon may occur, however, are very various; but in all certain conditions are necessary. The observer must be situated between the sun and a cloud from which the sun's rays are reflected. These rays are not reflected directly as from a polished surface, but are thrown back after refraction and reflection through and in the minute spheres of water which make up the cloud. Not all these drops can so act, but only such as fulfil the necessary optical conditions for a ray incident at the external surface to suffer internal reflection, and be transmitted after a second refraction to the observer's eye. All such drops must lie upon a circle symmetrically placed with reference to the right line joining the observer

and sun. If white light were homogeneous, the bow would be simply a thin bright line. But since white light is heterogeneous, and each constituent has a definite wave-length with corresponding refractive properties and a corresponding tint, the complete solar R. is composed of numerous concentric lines of various colours blending insensibly into each other from red through the intermediate tints to green, and so on to violet. A R., indeed, consists of a series of spectra (see SPECTRUM ANALYSIS), arranged side by side so as to form a circular band 2° broad. The size and height of this arc depend upon the position of the sun. The lower the sun the higher the R. The radius of the circle of which the bow forms a part is about 41°. The violet is innermost, the red outermost, and within the violet supernumerary arcs are sometimes seen. These are caused by interference. Frequently a secondary R. is observed, having a radius of about 52° and a breadth of 3' 30". In it the red is on the inside. It is produced by the final emergence of the ray from the drop after two internal reflections. The increased loss of light makes the secondary R. always much less brilliant than the primary. Rainbows of the third order have been seen, but they are of rare occurrence. The most usual circumstances, other than the ordinary rain-shower, under which rainbows appear, are in cascades and fountains, in the foam of the sea, or even by the action of the dewdrops. Such phenomena as lunar rainbows are also known. Here the source of light is the moon, and consequently the tints are not so brilliant as in the solar R. A secondary lunar R. is an extremely rare phenomenon.

Rain-Gauge is an apparatus for measuring the rainfall at any locality. The simplest and most trustworthy form consists of a vessel or receiver which communicates with the air above by means of a funnel. The quantity of rain collected is then measured either by being poured into a graduated vessel, or by having a graduated scale in the receiver itself. Much attention must be paid to the setting of the R.-G. in a suitable place.

Rai'ny Lake, on the boundary between Canada and Minnesota, lies 160 miles W. of Lake Superior, at an elevation of 1035 feet, and is 35 miles long by 5 of average breadth. It is fed by the river Nameken and other streams, and drains, by the Rainy Lake River 100 miles long, into the Lake of the Woods.

Raipur, the chief town of the district of the same name, Central Provinces, British India, 180 miles E. of Nagpur. Pop. (1872) 19,116. It is an old town, with a massive fort and many tanks, gardens, and temples. It has now a large trade. In 1875-76 the exports, chiefly oil-seeds and lac, were valued at £89,000; the imports, piece-goods, rice, metal-ware, &c., at £106,000. The main street is 2 miles long, well laid out, and the houses are ornamented with wood carving.—The district of R. is almost coextensive with the plateau of Chhattisgarh. Area, 11,885 sq. miles; pop. (1872) 1,093,405. The tableland is very fertile, but the surplus produce is, as yet, remote from a market. It is proposed to continue the railway from Nagpur, or to open a new line from Calcutta. The crops are rice, wheat, gram, kodo, and cotton.

Raised Sea-Beaches. See BEACHES, RAISED.

Rai'sins (Fr. *raisin*, 'grape'; Prov. *razim*, Span. *racimo*, Ital. *racemo*, from Lat. *racemus*) are the dried ripe grapes of certain varieties of the vine. These varieties are principally the Muscatel, Valencia, and Sultana grapes, cultivated in the countries bordering the Mediterranean Sea and the Greek Archipelago. Currants are a small variety of R. made from the currant or Corinthian grape grown in Greece and the Ionian Islands. Sultana R., cultivated in Turkey, are free from seeds or 'stones,' and consequently more valuable than the other kinds. To prepare R. the grapes are allowed to be dead ripe, after which they are plucked, scalded in a caustic saline ley, and dried by exposure to the sun for about a fortnight. R. are nutritious, cooling, and somewhat laxative, but a little indigestible. In addition to their extensive use as a dessert fruit and in puddings, &c., they are extensively employed in the preparation of British wines. The imports into the United Kingdom for the year 1876 amounted to 583,860 cwt., the duty on which was £204,351. These imports came from Spain, Asiatic Turkey, Italy, Greece, and other countries.

Raj'ah (*rājā*), the Hindu term for king or prince, which preserves the original Sanskrit form corresponding to Lat. *rex* and French *roi*. It is assumed by all sorts of petty chiefs, and is frequently conferred by the British Government, as an honorific title, upon meritorious individuals. In early times there was no higher rank; but now Oriental vanity is pleased with the invention of Maharajah ('great prince') and Adhi Rajah ('first prince'). The former of these is borne by most of the great Hindu feudatory chiefs, and is also conferred on British subjects. The chief of Oodeypoor (q. v.), the acknowledged leader of the Rajputs, bears the title of Rana, probably a corruption of R. Other common corruptions of the word are Roy (Rai), which was applied by the Mohammedans to Hindu civil officers of rank, and Row (Rao), which was originally a Mahratta title. Both these two have now become common personal names. The feminine of R. is Ranee; cf. Lat. *rex*, *regina*; Ger. *könig*, *konigin*.

Rajahmundry (*Rājā-mahēndravaram*), the chief town of the Godavery district, in the Madras Presidency, British India, just above the bifurcation of the delta of the Godavery river, 30 miles from the sea and 65 N.E. of Masulipatam. Pop. (1871) 19,738. The southern suburb is well laid out. The Government offices to the N. occupy the site of an old fort. Near the river are an ancient Hindu pagoda and a Mohammedan mosque bearing date 1324 A.D. There is a church, a provincial school teaching up to the university standard, and a Protestant mission with 400 converts. A permanent museum was built in the centre of a public garden in 1865. In the 12th c. R. was the capital of an independent Rajput dynasty, and it used to give its name to the British district. See *The Godavery District* by H. Morris (Lond. 1878).

Rajmehal ('royal estate'), a ruined town in the district of the Sonthal Pergunnahs, Bengal, British India, situated on high land a short distance from the right or S. bank of the Ganges, 137 miles by rail N. of Calcutta. It was chosen by the Moguls in 1592 as the seat of government in Bengal, and remained a place of great importance until the beginning of the present century, when the Ganges deserted its former course. The river now flows 4 miles away, and the palaces, mosques, and tombs of the Mohammedans have relapsed into jungle. In trade, also, it has been to a great extent supplanted by Sahelgunge. In 1876 77, however, piece-goods to the value of £184,000 were received at the railway station for distribution in the country round.

Rajpeep'la, the first native state in the Rewa Kanta Agency, India, in political connection with the government of Bombay. Area, 1514 sq. miles; pop. (1872) 120,036; revenue, £80,000, of which £6500 is paid as tribute to the Gaekwar, under British guarantee. Hills cover three-fourths of the area, producing teak and other timber. The lands to the N. along the Nerbudda river yield abundant crops of cotton, oil-seeds, tobacco, and sugarcane. The climate is unhealthy, and more than half the inhabitants belong to the wild tribe of Bheels. Nandod, the capital, has a pop. (1872) of 9768. The ruling family are Rajputs, and date back for 400 years.

Rajpūt ('the son of a Raja,' or prince), the general designation of the races in the N. and W. of India, who claim to be descended from the ancient dynasties of the sun and moon, forming the two great tribes of Suryavansi (Solar) and Chandravansi (Lunar), from whom the 36 royal clans are supposed to originate. There are, in addition, an innumerable number of minor clans of inferior rank. The Rajputs are generally regarded as the legitimate representatives of the Kshatriya or warrior caste of the primitive Hindu system; and as a rule they disdain employments which are not of a semi-military character. Many of them are landholders, and the poorer members are largely employed throughout the Peninsula as sepoy, policemen, door-porters, and private guards. The home of the race is the central tract of Rajputana, where their chiefs still exercise sovereignty; but they are also numerous N. in the Punjab, W. in Gujerat, and E. as far as Behar. The petty hill chieftains in all parts of India, even when evidently of aboriginal descent, claim to belong to this caste. According to the general census of 1868-72, the total number of Kshatriyas and Rajputs in British India amounts to more than five and a half millions, most numerous in Behar, the N.W. Provinces, Oude, and the Punjab. In addition, about 700,000 more of this caste in the Punjab are now Mohammedans in religion.

Rajpūtānā ('the land of the Rajputs,' or 'king's children'), an extensive tract in W. India, containing an aggregate of eighteen native states, subdivided under seven political agencies, but all subordinate to the Governor-General's Agent for R., whose official headquarters are at Mount Abu. Total area, about 128,126 sq. miles; pop. estimated at 9,000,000, of whom the great majority belong to wild tribes, such as Bheels and Mhairs. This tract is bounded N. by the Punjab, E. by the Native States of Central India, S. by the Native States of Bombay, and W. by the Bombay province of Scinde. There are no natural boundaries, but in the centre are the original strongholds of the ancient R. dynasties, and the limits are those imposed by successive conquerors of Mogul or Mahratta origin. Towards the E. lies the Thar, the great sandy desert of India; and the soil is nowhere fertile, being much broken by rocky ridges. After the Afghan Emperor, Shere Shah, had defeated the Rajput princes in a hard-fought battle, he is said to have remarked that he had hazarded the empire of India for a handful of *jowar*, a coarse millet which is the staple crop in this barren country. The rivers are insignificant, and there are no irrigation works proper, except the enormous tanks, or rather artificial lakes, constructed by former sovereigns. The Aravalli Mountains, running from N.E. to S.W., form a sort of watershed, dividing the country into two portions; the highest peak of Mount Abu is 5800 feet above the sea. In the N.E. is the salt lake of Sambhur, now leased to the British Government. The most valuable commercial products are opium (to which the Rajputs are themselves immoderately addicted) and building stone of various excellent kinds; there are also found copper, cobalt, &c. During the year 1874-75 the imports from the Punjab only into R. were valued at £1,146,000, chiefly piece-goods and sugar, in about equal proportions, metals, rice and other grains, and raw cotton; the exports from R. into the Punjab were valued at £524,000, chiefly salt, piece-goods, wheat and inferior grains, fruits, and raw cotton. In 1876-77 piece-goods were imported from Calcutta to the value of £121,000. Since the opening of the R. State Railway, running from Delhi to the Sambhur Salt Lake near Jeypore city, the main trade route is towards the N. A branch has since been opened to Agra, and the main line has been continued to Ajmere. By the end of 1875, the total number of miles open was 344; the capital expended, £2,155,216; and the net earnings of the year, £63,482. It is now contemplated to make two branches S., joining directly with the Bombay system at Ahmedabad and Indore; total length, 433 miles, at an estimated cost of £2,664,000, or a little more than £6000 per mile. These are all narrow gauge lines, but they will revolutionise the present commercial apathy of R. The British force stationed in R. consists of 42 Europeans and 4391 native soldiers.

Of the eighteen states into which R. is divided, three are Jat, and one, Tonk, is Mohammedan, while the rest are all governed by Rajput princes of ancient lineage. The acknowledged chief is the Rana of Oodeypur (q.v.) of Mewar, who traces his descent back for eighteen centuries. Other important states are Jeypore, Jodhpore, Kotah, Bikanir, Ulwar, and Jeysulmur, which are described under their several headings. The administration in all cases is of a feudal character, the barons claiming the same descent as their prince, and consequently a semi-independence. This strongly-developed feudal spirit has proved both the strength and weakness of R. It enabled the princes to offer an heroic resistance, such as the annals of the world will hardly parallel, to the Mohammedan invaders; but subsequently it divided the great states into little fragments, rendering them an easy prey to the Mahrattas of the last century; and it forms now the main obstacle to the establishment of order. British connection with R. dates from 1803, when the Marquis of Wellesley, in pursuance of his policy of universal British supremacy for the sake of India, enforced treaties on some of the states, by which they were protected from marauders in consideration of paying tribute. This policy was extended by Lord Hastings in 1817.

The great blot on the Rajput character, besides opium intoxication and laziness, is female infanticide. In 1818 it was ascertained that among the offspring of 8000 married Jhareja Rajputs not more than 60 females were living. The cause of this crime is to be found in the necessity that exists for marrying into another clan, and for spending enormous sums on the wedding. 'The parents hope that the female children born to them may die; and very moderate ill-treatment is sufficient to secure their

wish.' Continuous efforts have been made by the British officials to check this barbarous usage, and no doubt with some success. No trustworthy statistics are available for R.; but the condition of things may be inferred from the fact that the general census of 1868-72 shows that throughout British India the percentage of females to the total population, which in some places falls as low as 42 (in England the average is 52), varies directly with the presence of a Rajput element. Even so late as 1872, in one village in the N.W. Provinces, only 8 girls were found to 80 boys. A special Act of the Legislature was passed in 1870 to enforce appropriate regulations in such cases. Tod's *Annals of Rajasthan*, Malcolm's *Memoir of Central India* (2 vols. Lond. 1823), *Annual Bluebooks on the Moral and Material Progress of India* (Lond.), *Annual Reports of the Governor-General's Agent for R.* (Printed at the Foreign Office Press, Calcutta), an article in the *Edinburgh Review* for July, 1876, and Rousselet, *India and its Native Princes* (Lond. 2d ed. 1877).

Rake, a well-known horticultural and agricultural implement, which in its simplest form consists of a shaft or handle, to which a cross-bar is attached, studded at regular intervals with wooden or iron teeth of uniform length. The garden R. is a small implement with short teeth, used for smoothing tilled grounds and walks, collecting weeds, and like purposes. The field R. is of two kinds—the hand R., such as is used in haymaking, and the harvest R. The latter is frequently a heavy implement, dragged by a horse, with its teeth or tines so detached from each other that they follow irregularities and depressions of the ground.

Raking Moulding, in architecture, a moulding which is neither vertical nor horizontal, but runs at an angle.

Rakoczymarsch, a heroic composition, the *Marseillaise* of the Magyars. Its origin is unknown, but it was popular in the early part of the 17th c., and owes its name probably to Franz Rakoczy II. of Transylvania. During the Hungarian struggle for independence, its performance was on several occasions suppressed by the Austrian Government. It fired the enthusiasm of the revolutionary forces in 1848, and its music was set to patriotic poems.

Raleigh, the capital of North Carolina, U.S., on the Raleigh and Gaston and North Carolina and Chatham railroads. It has a fine granite Capitol, a State penitentiary, institutions for the insane, deaf, dumb, and blind, 8 churches, 2 daily and 8 weekly newspapers, and 3 banks. It has two foundries and a manufactory of steam-engines, and is an extensive cotton mart, handling about 40,000 bales annually. From the fineness of its native oaks, it is known as the 'City of Oaks.' Pop. (1870) 7790.

Raleigh, Sir Walter, born in 1552 at the manor-house of Hayes, on the E. coast of Devon, entered Oriel College, Oxford, in 1566, and three years later quitted it without a degree, to serve his apprenticeship in arms among the Huguenots. He shared in the retreat of Moncontour, and after staying six years in France and seeing a few months' service in the Netherlands, sailed in 1578 with his half-brother, Sir Humphrey Gilbert, in search of the 'Unknown Goal.' A smart brush with the Spaniards drove them back, and in 1580 R. led 100 men to assist in putting down the revolt in the 'common-wool or rather common-woe' of Ireland. He was one of the slayers of 600 surrendered Spaniards at the Smerwick fort, received 12,000 acres of the confiscated Desmond estates; then, having quarrelled with the deputy, Lord Grey, returned to England in the winter of 1581. He entered on court life under Leicester's patronage, 'got the Queen's ear at a trice, being taken by her for a kind of oracle,' and, charged with a special mission to the Prince of Orange, attended Anjou on his entry into Antwerp (1582). Receiving in 1584 a grant of any lands not actually held by Christian princes, he sent three several expeditions to explore and colonise the coast to the N. of Florida, and on the region there discovered the Virgin Queen bestowed the name Virginia, whilst knighting R. (1585). After spending some £40,000 upon his colony, R. abandoned it in 1590, though not till he had introduced two of its products into Europe, potatoes and 'an herbe called by the natives *ypohow*, by the Spaniards *tobacco*.' Meanwhile he sat in Parliament from 1585, received the post of Warden of the Stannaries, and in 1587 was appointed Captain of the Queen's Guard. At the coming of the Armada (1588) he was employed on the coast defences, so could not join the fleet

till July 23, nor can we more than guess how valiantly he quitted himself in the busy week that followed. Then Leicester died, and R., jealous of Essex, withdrew to Ireland, there met with 'Colin Clout,' and brought him back with him to 'Gloriana.' Next for seducing Bessy Throgmorton, a maid of honour, Elizabeth committed R. to the Tower (1592); whilst he lay there, a ship of his captured a splendid Spanish prize, and on release he married the cause of his disgrace. He must, however, retire to his seat at Sherborne, to dream of El Dorado, that wondrous land beyond the Orinoco which he should never find. But if his search for it in 1595 proved vain, he showed at least the way to win the natives' love, penetrated Guiana as far as the Falls of Caroli, and sacked San José, a town of Trinidad. At the taking of Cadiz (1596) R. headed the English fleet, and his was all the glory of that grand success; his also were the laurels of the 'Island Voyage' in 1597, when, without waiting for Essex to arrive, he carried Fayal in the Azores by storm, widening thereby the jealousy that only ended with his rival's death (1601). In 1600 R. was made Governor of Jersey; in 1603 there arose a king which knew him not, nay, hated him for Essex' sake. And within half a year he, Spain's great enemy, was sentenced to death at Winchester for conspiracy with Spain. As Kingsley well observes, 'but one thing comes brightly out of the infinite confusion and mystery of this dark Cobham Plot, and that is R.'s innocence.' James durst not, however, kill him yet; a self-inflicted wound soon healed, and so for thirteen years the Tower became his cage, where he composed the great unfinished *History of the World* (1614), brewed cordials in a hen-house, and gave sage counsels to Prince Henry. At length in 1616 he was let go, unpardoned and *non ens* in law, and in April of the following year sailed for the last time Westward Ho! with a 'scum of men,' a commission thwarting him at every turn, and the Spaniards forewarned of his design. He sailed in quest of a Guiana gold-mine, whether real, or fancied, or trumped up as a pretext for release, is still unknown. Sickness and storm assailed the expedition from the first; R. himself lay fever-stricken; the storming of San Thomé cost his firstborn's life; and Keymis, oldest and truest of his captains, was goaded to suicide by the father's taunts. But loyal to his word, though with 'broken brains,' R. returned to Plymouth, there to be met by his kinsman Sir 'Judas' Stukeley, who, after tempting him to an abortive flight to France, that so his enemies might have a surer handle, arrested and lodged him in the Tower. On 29th October 1618 R. died bravely and cheerfully on Whitehall scaffold, a base king's sacrifice to Spanish pride, nominally under the sentence of fifteen years before. There died with him the Elizabethan hero age, though he was not the greatest of its heroes. 'Water' had been his nickname with the Queen; 'unstable as water' ran maybe in her mind. For R. had all the making of a great soldier, statesman, or navigator, but hardly of the three combined. Yet to combine them was always his ambition; what wonder if it o'erlept itself and fell? His possible achievements may be inferred from what he really did. His *History of the World*, 'writ by the captive eagle with his own wing's quill,' belongs in style as well as date to the age of pure English undefiled; Cromwell commended it to his son, and Hampden was at the cost of transcribing 3000 of its sheets. His *Truth of the Fight about the Isles of the Azores* (1591) is known to many now through Tennyson's *Revenge* (1878); how closely the poet has followed the historian comparison will show. And of his poems, the *Lie* at least discovers no mean member of the Mermaid Club. In Parliament, in an age of petty restrictions, he advocated freedom of tillage, freedom of church-going, and repeal of monopolies; his valour in the field and on the sea 'tossed him,' as even Naughton owns, 'from nothing up to greatness.' But it is chiefly as the planter of England's earliest colony, as the first to recognise that Spain must be foiled with her own weapons, that this Ulysses of over-many wiles deserves our praise, and, as the victim of the author of the *Counterblast*, our pity. R.'s *Complete Works* were published at Oxford (8 vols. 1829); his *Discovery of Guiana* has been separately edited for the Hakluyt Society by Sir R. Schomburgk (1848). The best Lives of him are by Tytler (1853), Edwardes (1868), and Mrs. Creighton (1877). See also vol. i. of Kingsley's *Miscellanies* (1859), and S. R. Gardiner's *History of England, 1603-16* (1863).

Râles, sometimes called Ronchi or Rattles, are thoracic sounds of a morbid type evolved during the acts of respiration.

Râma, a favourite hero of Hindu mythology, identified with three incarnations of Vishnu as Parasuram, Ramchandra, and Balarama. His adventures and those of his wife Sita are described in the *Ramayana* and the *Vishnu Purana*; his most popular exploit is the conquest of Lanka or Ceylon, and the destruction of the demon giant Ravana.

Ram'adan, or **Ramazan**, the ninth month of the Mohammedan year, which previously to the time of Mohammed was dedicated by the Arabs to excessive drinking, was by Mohammed set apart for fasting, because in it 'the Koran was sent down from heaven.' The fast is extremely strict during the day, so that Mohammedans must abstain entirely from eating, drinking, and intercourse with women. But during the night they may refresh themselves with eating and drinking, and enjoy the company of their wives. From the fast of R. none are excused except travellers and those whose health would suffer by observing it; and this exemption has to be compensated by fasting an equal number of days as soon as the impediment is removed.

Râmânuja, the founder of a sect of Vishnuvite Hindus who are numerous at the present day in S. India. He was born near Madras in the middle of the 12th c., and is known to have lived at the holy places of Conjeeveram and Srirangam. His teaching was founded upon the supremacy of Vishnu over the other members of the Hindu Trinity, as the cause and creator of all things. In N. India the similar sect takes its name from Ramananda, said to have flourished at Benares in the 14th c. To Kabir, a pupil of Ramananda, may be traced the monotheism of the Sikhs. See Monier Williams' *Hinduism* (1877).

Râmâyana ('the goings of Rama'), one of the two great epic poems of Sanskrit literature, relating the adventures of Rama, one of the incarnations of the god Vishnu. It is affirmed to be undoubtedly the work of one hand, traditionally that of Valmiki; and it thus preserves a general unity, which renders it superior as a work of art to the rival epic of the *Mahabharata*. On critical investigation, the text which is preserved reveals two distinct recensions. It contains 24,000 verses, arranged in seven books. The date of its composition is assigned to the 3d c. B.C.

Rambouillet, Catherine, Marquise de, the founder of the famous literary society which took her name, and met in the Hôtel de R., in the vicinity of the present Palais-Royal. Born at Rome in 1588, the daughter of the Marchese di Pisani was married at the age of twelve to Charles d'Angennes, who on the death of his father became Marquis de R. in 1611. Beautiful and accomplished, she turned with disgust from the licentious court of Henri IV., and devoted her leisure to classical studies, gradually gathering around her an illustrious circle, which was greatly extended on the death of the king. The Hôtel de R. she luxuriantly refitted in a style opposed to the fashion, but in such pure taste that Marie de Medici ordered the architect of the Luxembourg to follow its designs. When only thirty-five years of age, Madame de R. was attacked by a peculiar malady of which the physicians could neither determine the nature nor relieve the suffering. Not too ill, however, to receive company, she generally reclined on a bed placed in an elegant alcove of the great *chambre bleue*. Here she could be screened off, admitting only her more intimate friends to the space around the bed known as the *ruelle*. The *salons* of the Marquise attracted the choicest wits of Paris and the most distinguished members of the French aristocracy, and the Hôtel de R. for about fifty years remained the fashionable rendezvous of all that was worthy and brilliant in the society of France. The list of visitors includes Malherbe, Racan, Corneille, Scarron, Saint-Evremond, Larocheffoucauld, Richelieu, and Boileau; while a charming coterie, famed equally for beauty and culture, was formed by Mademoiselle de Scudery, Madame de Sévigné, Mademoiselle de la Vergne, Madame Lafayette, the Marquise de Sablé, and the Duchess de Longueville. The fame of the Hôtel de R. led to the formation of many minor societies, and for a time *bas-bleuism* was the rage. Literary ladies were *alcovists*, and the clubs became mere corollaries of the *ruelles*. Even Madame de R.'s infirmities were imitated, and fashionable belles gave audience in coquettish *déshabille*. Against these follies and pedantries Molière aimed his *Précieuses Ridicules*. The Hôtel de R. declined greatly on the ascendancy of Louis Quatorze, and the Marquise died at Paris, 2d December 1665. The precursor of the Academy, the Hôtel de R. diffused a taste for literature, and

aided the development of the language, while it raised the moral tone of society and imparted new life to the art of conversation. See Somaize, *Dictionnaire des Précieuses* (1661), Roederer, *Mémoires pour servir à l'Histoire de la Société polie en France pendant le XVII^e Siècle* (1835), Livet, *Précieuses et Précieuses* (1859).

Rameau, Jean Philippe, the most celebrated French musician of the 18th c., was born at Dijon, September 25, 1683. After a professional visit to Milan in 1701, he spent several years in wandering about the south of France as first violinist to a theatrical company, and giving performances on the organ. In 1717 he went to Paris, and was organist in succession in several churches. He published a *Traité d'Harmonie* in 1722 (there is an undated English translation by Griffith Jones), and his *Nouveau Système de Musique Théorique* in 1726. He wrote many pieces for the church and the theatre, and was ultimately appointed manager of the opera, where he produced numerous operas and ballets. The former include *Hippolyte and Aricie* (1732), *Castor and Pollux* (1737), *Dardanus* (1743), *Pygmalion* (1748), *Zoroastre* (1749), *Acanthe and Cléopâtre* (1751), and *Les Paladins* (1760). He published his *Dissertation sur le Principe de l'Harmonie* at Paris in 1750. R. died at Paris, 12th September 1764. His character as a theorist stands deservedly high, and his compositions, though now obsolete, were considered at the time both scientific and brilliant. See Fétis, *Biographie universelle des Musiciens* (new ed. 1878).

Ramesses was the name of thirteen of the kings of ancient Egypt. See EGYPT and PHARAOH.

Rameswaram (from *Rama* and *iswar* = 'god'), the chief town on the E. shore of the island of the same name which forms part of the district of Madura, Madras, British India: pop. (1871), together with the adjacent town of Paumbaum (q. v.), 9407. Close by is a fresh-water tank 3 miles in circumference, on the bank of which is the celebrated pagoda, one of the finest buildings in India, annually frequented by 30,000 pilgrims. This is approached through a gateway 100 feet high, of handsomely carved granite, which opens into a cloister 600 feet square. The town itself is well built, and is the residence of many wealthy priests and traders. The island of R., which is about 20 miles long and of varying width, forms the first link in the chain connecting the mainland of India with Ceylon, by means of Adam's Bridge. For the proposed ship-canal across it, see PALK STRAITS. Its sanctity in Hindu eyes is connected with Rama's invasion of Ceylon; but local tradition, confirmed by geological evidence, asserts that it was only separated from the mainland by a hurricane in the 15th c.

Ramillies, a village of Brabant, Belgium, 13½ miles N. of Namur by rail, where Marlborough at the head of the allies defeated the French under Villeroy and the Elector of Bavaria, May 23, 1706. In an hour's engagement the French lost baggage, artillery, and 20,000 men, and with them the whole of the Spanish Netherlands—Antwerp, Brussels, and other towns surrendering to the conqueror without a blow.

Ramler, Karl Wilhelm, a German lyrical poet, born at Kolberg, 15th February 1725, studied at Halle, was from 1748 to 1790 a teacher in the Cadets' School at Berlin, and from 1790 to 1796 director of the theatre. He died 11th April 1798. Of the poems of R. all that are now interesting are his imitations of antique metres, as his *Oden aus dem Horaz* (Berl. 1769), which served as models to Voss and others. See his *Poetische Werke* by Göckingk (2 vols. Berl. 1800-1), and Heinsius, *Versuch einer Biographischen Skizze R.'s* (Berl. 1798).

Rammelsberg, a mountain in the Upper Harz, S. of the town of Goslar (q. v.), 2041 feet above the sea. Its mines have since 1668 yielded gold, silver, lead, copper, zinc, vitriol, sulphur, and alum.

Rammohun Roy, Rajah, the founder of the Brahmo Somaj (q. v.), or reformed Theistic sect of Hindus, and one of the most original men whom India has produced in later times. He was born in Burdwan district in Bengal in 1774, and early learned the classic languages of the East, and studied the Shastras, the Koran, and the Bible. In 1820 he published *The Principles of Jesus, the Guide to Peace and Happiness*, and in 1830 organised a society for prayer-meetings, based upon adoration of the One and Universal God of Goodness. He adhered closer to the Vedas than his followers have done. Shortly afterwards he came

to England, partly on a mission from the Mogul Emperor of Delhi. He published English translations of the principal books of the Vedas and other Indian works. He died at Stapleton Park, near Bristol, 27th September 1833. See Mary Carpenter's *Rajah R. R.'s Last Days* (Lond. 1866).

Rámnuggur ('town of Rama'), a town in the district of Benares, N.W. Provinces, British India, on the right bank of the Ganges, and 4 miles S. of Benares. Pop. (1872) 8916. It is celebrated for the fort or residence of the Rajah of Benares, built of stone, which is one of the handsomest specimens of modern Hindu architecture.

Ram'pant (Old Fr. 'climbing'), in heraldry, an epithet applied to a lion standing erect on his hind legs, with the tail and one of the fore legs elevated, and the head in profile, as the red lion in the royal arms of Scotland.

Ramphorhynchus, a curious genus of extinct reptiles, the fossil remains of which occur in Mesozoic rocks. There were no teeth in the front portion of the jaws, which apparently existed in the form of a horny beak. R. was one of the flying reptiles allied to the *Pterodactyl* (q. v.).

Ram'pion, or **Ramps**, is a name applied to *Campanula Rapunculus* formerly much cultivated in gardens for its roots and its leaves, both being used in a raw state as a salad mixture, and the latter boiled as spinach. The root has a flavour of walnuts. The plant is a biennial, and has a wide distribution in Europe, extending to W. Siberia and N. Africa. In Britain it is a native of gravelly ground in S. England.

Ramps, in fortification, obliquely sloping passages 10 or 12 feet broad, cut in the interior talus or slope of a rampart, for the ascent or descent of troops and cannon.

Rámpur (= city of the god Rama), the capital of a native state in India, in political connection with the government of the N.W. Provinces, on the left bank of the Kosila, a tributary of the Ganges, and 18 miles E. of Moradabad. Pop. 68,000. It is a straggling town, with two forts and several handsome palaces. There is a special manufacture of a kind of damask. The state of R. lies W. from Bareilly, in the centre of the N.W. Provinces. Area, 945 sq. miles; pop. 507,013; revenue, £146,000. Army, 28 guns, 500 horse, and 1000 foot. The exports are rice, sugar, and hides; the imports are elephants, horses, English cloth, spices, and salt. The ruling family, whose title is Nawab, came from Afghanistan towards the end of the 17th c., and the name of Rohilkund is said to be derived from their original home. For loyal services during the Mutiny of 1857, the late Nawab received an increase of territory, yielding £13,000 per annum.

Rámpur, the capital of the native state of Bussahir, Punjab, British India, situated amid the Himalayas, on the left bank of the Sutlej, 50 miles N.E. of Beelaspur. The architecture is of a Tibetan character, but there are many temples frequented by Hindu pilgrims. The river, which runs through a gorge, is here crossed by a swing bridge of ropes. R. is celebrated as an emporium of trans-Himalayan trade, and has given its name to the *chuddurs* or shawls made from the wool of the mountain sheep, which are themselves used as the beasts of burden. Borax is also an important article of trade.

Rámpur Beaulah, the chief town of the district of Rajshahye, Bengal, British India, on the left or N. bank of the Ganges, 125 miles N. of Calcutta. Pop. (1872) 22,291. In the early part of last century it was the site of a commercial factory, and the administrative headquarters were moved here in 1825. There is an important English school, which is growing into a college, and is well supported by the landowners. A large trade is conducted on the Ganges. In 1876-77 the registered exports were valued at £251,000 of raw silk; the imports at £199,000, including £100,000 of refined sugar.

Ram'say, Allan, was born at Leadhills, Lanarkshire, October 15, 1686. His father, Robert R., manager of Lord Hopetoun's lead mines, died when Allan was little more than an infant; and Mrs. R. soon after married a landowner in the neighbourhood named Crighton. Allan got the benefit of the parish school, learned as much Latin as enabled him 'to read Horace faintly in the original,' and in 1700 was apprenticed to a wig-maker in Edinburgh. At Edinburgh he soon became known for a thoroughly sociable fellow; and as small clubs held in taverns were patronised then by all classes, he connected himself with

more than one of these. His most regular attendance was given to the Easy Club, of which he became poet laureate, and which was usually favoured with the first reading of his poems. The members of this society were known by assumed names; R. was first Isaac Bickerstaff, and afterwards Gawin Douglas. He seems to have continued in the wigmaking business until thirty, although long before that he had conjoined with it the dignity of authorship. He was never ashamed of his early profession, and turned away sneers by remarking that he 'thatched the out and inside of many a shrewd and witty pate.' In 1712 he married Christian Ross, a lawyer's daughter. At the *Mercury*, opposite Niddry's Wynd, he was now established as bookseller and publisher, and it was the custom of parents to send their children to his shop for 'his last piece,' which he would hand over the counter in the shape of a penny broadsheet. In this manner appeared 'Edinburgh's Salutation to my Lord Marquess of Caernarvon' (1720) and others such. His first considerable attempt at publication was the production of King James's *Christ's Kirk on the Green*, with an additional canto by himself. The rich, broad humour here displayed caused the book to be sold rapidly, and after two years he brought out a second edition, with still another canto, as successful as the former. His poems now amounted to so considerable a number that he collected them (1721) into a quarto volume, the subscriptions for which brought him four hundred guineas. It is a curious sign of the times that he dedicated to 'The Most Beautiful the British Ladies,' a book stained in many places with the grossest indelicacy. He produced in 1722 his vigorous *Fables and Tales*, and in 1723 *The Monk and the Miller's Wife*, a Chaucerian tale, which Woodhouselee declares 'would be of itself his passport to immortality.' In 1724 appeared his poem on *Health*, and the first volume of the *Tea-Table Miscellany*, a *Collection of Songs, Scottish and English*. October of the same year welcomed his *Evergreen*, being a *Collection of Scots Poems wrote by the Ingenious before 1600*. This is compiled chiefly from the Bannatyne MS. which had been lent to R. But his conscience as an antiquarian editor was too easy; he freely cut and patched wherever it seemed good to him, his single aim being to catch the public taste. Of two poems of his own introduced into the *Evergreen*—'The Vision' and 'The Eagle and the Robin,'—the former is his greatest effort of imagination. It is a political allegory referring to the Pretender, and rivals the best work of Dunbar. R.'s purest, truest poem, *The Gentle Shepherd*, appeared in 1725. Its germ had been printed in 1718 in a separate pastoral, entitled *Patie and Roger*, followed in 1721 by the song *Patie and Peggy*, and in 1723 by the sequel *Jenny and Meggie*. These pieces were of such merit as to induce R.'s friends to ask him to undertake a pastoral poem descriptive of life in the S. of Scotland. Dr. Pennecuik, a brother poet, furnished him with the framework of the drama. The scenery is now generally supposed to be that around Newhall House, twelve miles from Edinburgh. *The Gentle Shepherd* is a Scotch eclogue *suu generis*. It does not ape the classical; no line of it is out of harmony with the spirit of Scottish peasant life; yet its beauties are those of Theocritus. It had reached ten editions in 1750, and has since then gone through at least forty more. The remaining three volumes of the *Tea-Table Miscellany* appeared successively in 1725, 1727, and 1740. A second collection of R.'s poems was made in 1728, and a book entitled *Thirty Fables* followed in 1730. His last work was a collection of *Scots Proverbs* (1736). In 1726 he had removed his business to the Luckenbooths, where he changed his sign of Mercury for the heads of Drummond and Ben Jonson. Here he established the first circulating library in the kingdom. It appears to have succeeded well, for Wodrow notes that in 1728 the magistrates attempted to suppress it on account of its influence on the youth of the city. These magistrates also fell foul of a theatrical speculation of R.'s, and, refusing him a licence for plays, rendered useless a theatre he had built at great expense in Carrubber's Close. This was the single piece of ill-luck in the life of the poet, who, like his contemporary Pope, was always able to coin his verses into gold. In his sixtieth year he retired from active business, and built himself a quaint villa, 'like a goose-pie,' on the Castle Hill, where it still remains, commanding a view that is scarcely to be surpassed anywhere. This Scottish Horace passed through old age, though burdened by disease, with Horatian equanimity, and died on the 7th of January 1758. His statue was erected in Princes Street, Edinburgh.

burgh, in 1865. A neat and careful edition of *The Gentle Shepherd*, with memoir, was published by Ross (Edin. 1875). Chalmers' edition of R.'s complete works (1800) has been superseded by that of Gardner (2 vols. Paisley, 1877), who supplies a full biography.—**Allan B.**, son of the preceding, was born at Edinburgh, October 1713. He pursued the profession of artist, a profession his father had at one time contemplated, lived on friendly terms with Dr. Johnson and Sir Joshua Reynolds, acquired considerable political and literary influence, and rose to such eminence in art as to be appointed portrait painter to George III. About half-a-dozen short political tracts were published by him anonymously. R. died at Dover, August 10, 1784.

Ramsay, Edward Bannerman Burnett, was born at Aberdeen, 31st January 1793. His father, Alexander, second son of Sir Thomas Burnett, Bart., of Leys, was Sheriff of Kincardineshire, where the family estates lay. Edward, when very young, was taken in hand by his uncle Sir Alexander R., who sent him to school in Yorkshire, at Harsley, near his own house. Harsley was the most retired village in the county. In its church the Bible lay in chains of Edward VI.'s period; no turnpike road passed through it; and all the letters of the villagers were written by Sir Alexander's gardener. In the second series of the *Reminiscences* will be found an account of the quaint surroundings and time-honoured usages amid which R.'s youth was passed. Sir Alexander died in 1806, leaving the estates to Edward's father, who obtained a baronetcy from Fox. In 1815 Edward graduated at St. John's College, Cambridge, and next year he obtained the curacy of Rodden, Somersetshire. This charge he soon conjoined with that of Buckland Dinham. An account of his work among the Methodists of Buckland was written by Dr. Guthrie in the *Sunday Magazine* for January 1865. In 1823 he removed to Edinburgh, where he became first incumbent of St. George's Episcopal Chapel, next, incumbent of St. Paul's Church, Carrubber's Close (1826), in 1827 assistant minister of St. John's, and in 1846 Dean of the Diocese of Edinburgh. He was offered the Bishopric of New Brunswick, that of Glasgow, and the position of Coadjutor-Bishop of Edinburgh; but declined the preferment. His *Advent Sermons* appeared in 1850, *Diversities of Christian Character* in 1858, *Christian Life and Manual of Catechising* in 1859, *On the Canon Law of the Episcopal Church* in 1861, and *Christian Responsibility* in 1864. These represent the literary work he did as a Churchman. He published in 1827 a *Memoir of Sir J. E. Smith*, in 1850 a *Memoir of Chalmers*, in 1862 *Genius and Works of Handel*, in 1866 *Preachers and Preaching*, in 1868 *Pulpit Table-Talk*, and in 1869 *The Art of Reading and Preaching Distinctly*. In 1857 appeared the work which has carried the best of Scotch humour over the world, *Reminiscences of Scottish Life and Character*. It had first taken the form of a little book of fifty pages, entitled *Some Changes in Social Life and Habits*. This kindly humourist, who occupied a unique and delightful position in Edinburgh society, died 27th December 1872. In 1873 appeared *Memorials of Dean R.*, by Rogers; the 1874 edition of the *Reminiscences* (22 editions have appeared) contains an appreciative biography of the author by his old friend Cosmo Innes.

Ramsay, William, youngest son of Sir W. Ramsay of Bamff, was born in 1806, and educated at the universities of Edinburgh and Glasgow. He graduated B.A. at Trinity College, Cambridge, in 1831, and two years before this had begun to act as Professor of Mathematics in Glasgow. In 1831 he resigned the chair of Mathematics for that of Humanity. He contributed largely to Dr. Smith's *Classical Dictionary*, and published *Selections from Ovid and Tibullus* (new ed. 1859), *Manual of Roman Antiquities* (4th ed. 1859), a fine annotated edition of *Exercitia pro Cluentio*, since adopted by the Clarendon Press (1869), and *Manual of Latin Prosody* (1859). R. died 12th February, 1865. R. was a ripe scholar, and poured forth his learning with a certain diffuse eloquence that enraptured students. Tradition in Glasgow College still retains many of his humorous sayings and doings. He was succeeded in the chair of Humanity by his nephew, George R., who still (1878) holds it.

Ramsden, Jesse, an inventor and maker of scientific instruments, was born near Halifax, Yorkshire, in 1735, received a good education, and began the pursuit in which he became

famous, after being for several years a cloth-dresser. He married the daughter of Dolland (q. v.), and thus acquired an interest in the letters-patent for achromatic telescopes. For the chief observatories throughout Europe he constructed instruments which excited general wonder by their accuracy and the perfection of their object-glasses. He reduced the possible error of the sextant from 5' to 30" of a degree, and invented a dividing machine, which ensured greater certainty and rapidity. One of his many skilful productions was the theodolite used by General Roy. He died at Brighton, November 5, 1800, leaving great part of a moderate fortune to be divided among his workmen.

Ramsey, a seaport in the Isle of Man, 12 miles N.N.E. of Douglas, has a courthouse, grammar-school, and small harbour, with a lighthouse and breakwater. There is weekly steam communication with Liverpool and Whitehaven. Pop. (1871) 3934.

Ramsgate (from *Rium*, the British name for Thanet, and *gate*, 'a road or passage,' referring to the break in the chalk cliffs which here occurs), a seaport and watering-place of Kent, on the Margate branch of the South-Eastern Railway, 4 miles S. of Margate, and 75 miles S.E. of London. It is now a well-built and handsome town, commanding a fine view over the Downs, Pegwell Bay, and, in clear weather, the French coast. Its commercial importance began early in the 18th c. Its present harbour, 40 acres in extent, protected on the E. by a breakwater 3000 feet long, and on the W. by another half that length, serves as a harbour of refuge for the Downs. In 1877 452 vessels, with an aggregate tonnage of 46,252, entered and cleared. Pop. (1871) 14,640, which is very largely increased in the season, from the middle of summer to the end of autumn. In 1877 was opened the Granville Marina, a large sea-garden on the beach, including a dining-hall, promenade, concert-hall, theatre, and bazaar, and an hotel on the cliff above, surmounted by a tower 175 feet high. R. has some ropeworks, and a shipbuilding industry.

Ramshorns, in fortification, a sort of low, semicircular work invented by Belidor, sometimes erected in the ditch of a fortification to serve instead of Tenaillles (q. v.).

Ramskin, or **Sef-ton Cake**, a cake in which the dough is baked up with skim-milk or grated Parmesan cheese. It is rolled out thin, glazed with white of egg, and after firing, is eaten hot.

Ram-Til, an Indian name for the Black Til (*Guizotia oleifera*), a small herb belonging to the *Compositæ*. The plant is commonly cultivated in Mysore and the Deccan for the sweet-tasted oil obtained from the seed. Besides the home consumption, it forms an article of export to Europe.

Ramus, or **La Ramée**, **Pierre**, born in 1515 at Cuth, in Vermandois, came to Paris a peasant boy of twelve, and there for nine years was by day a servant, a student only at night. After taking his master's degree (1536) he opened a course of lectures, the boldness and novelty of whose opinions caused their suppression, and would have brought their author to the galleys but for two powerful patrons, the Cardinals de Bourbon and Lorraine. Through them he was appointed president of the Collège de Presles (1545) and Professor of Eloquence and Philosophy in the Collège Royal (1551), still, however, incurring the frequent censures of the University. At length his adoption of the Reformed faith (1561), by redoubling the animosity of foes and breaking existing friendships, forced R. to fly from Paris, whither he returned only to fall in the massacre of St. Bartholomew, August 26, 1572. The paradox of R.'s M.A. thesis, 'That all in Aristotle is false,' forms the text of all his later teaching, wherein he combated the philosophy of the Middle Ages with no small success. Strangely enough it was itself founded on antiquity. 'I find,' he said, 'to my great wonderment that neither Cicero nor Virgil took any account in their writings of the laws of the *Organum*. This wonderment increased when, passing on to Plato, I read neither subtle rules nor methodical arguments. Socrates was content with sensible discussion; he would have us examine and bring reason rather than authority to the task. Why, then,' he proceeds to ask, 'can we not Socratise a little?' And before that question the mists of Scholasticism lifted, clearing more and more as R. proceeded to publish his destructive *Aristotelicæ Animadversiones* (1543); *Rhetoricæ Distinctiones* (1549); *Pro Philosophicâ Disciplinâ* (1551), and *Dialecticæ* (1555), by which he opened up a path for the constructive genius of Bacon and Descartes. He was also one of the first to

recognise the Copernican system, and in his *Grammaire Française* (1562) advanced a 'neographic' method two centuries before the lexicographers, distinguishing *j* from *i* and *v* from *u*. See Waddington, *R., sa Vie, ses Écrits et ses Opinions* (Par. 1855), and Desmazes, *Pierre R., Professeur au Collège de France, sa Vie, ses Écrits, sa Mort* (Par. 1864).

Rana and **Ranidæ**. See FROG.

Ranocé, **Armand-Jean le Bouthillier de**, born at Paris, January 9, 1626, received the tonsure in his tenth year, and in 1639 dedicated to his god-father, Cardinal Richelieu, a commentary on Anacreon. With such tastes and such a sponsor, little wonder that he led a gay, profligate life even after his assumption of the priesthood in 1651. The legend of his conversion is horrible, if apocryphal,—how, climbing one night through his mistress's window, he was confronted by her head lying John-Baptist-like in a charger, she having died in his absence, and the coffin proving too short to receive her. Certain at least it is that in 1663 R. suddenly resigned an enormous plurality of benefices, turned Trappist, and, himself a reformed man, proceeded to reform others by elaborating the present austere rule of his order (see TRAPPISTS). He died in the odour of sanctity at Soligny-la-Trappe, October 27, 1700, leaving behind him *Relations de la Vie de quelques Religieux de l'Abbaye de la Trappe* (4 vols. 1696), *Lettres de Piété* (2 vols. 1701-2), and other prolix but devout treatises. A collection of his letters was published by B. Gonod (Cler. 1846), and his *Life* has been written by De Tillemont (1712), D'Exauvillez (1842, new ed. 1868), Chateaubriand (1844), and Dubois (1866).

Ran'cho (Span. 'a messroom') is a word denoting in Mexico and California a rude hut used by herdsmen on the plains, and is opposed to *hacienda*, a farm. From it is derived the name *rancheros*, for the half-breed herdsmen of Mexico, a race of daring riders and huntsmen, among whom are recruited the strength of the Mexican army—its guerilla cavalry. *Rancho*, a corruption of R., is now applied in California to any large farm, but especially to those devoted to stock-raising.

Rancidity is the strong, penetrating, disagreeable odour acquired by oils and fats after some exposure to the air. See OILS.

Randazzo, a town of Sicily, province of Catania, in the Val Demone, 2536 feet above the sea, on the river Alcantara, 32 miles N.W. of Acireale, and 11 miles N. by W. of the crater of Etna. Its finest churches are S. Maria (Norman of the 13th c.), and S. Niccolo, of alternate courses of black and white stone. Pop. (1874), 7900.

Randers ('the town on the foreland'), a town of Denmark, in N. Jutland, on the Guden, 8 miles W. of its entrance into the Randersfjord, and 19 N.N.W. of Aarhus by rail. It is compactly built, and has one church, St. Mortens (14th c., restored 1870), a synagogue (1858), a hospital (1868), a 'Lærd Skole,' and four other schools. In 1874 there were in R. thirteen brandy distilleries. Brewing, cotton-weaving, and the manufacture of machinery, gloves, chicory, and tobacco are carried on, and there is considerable trade in agricultural products. Before the Reformation R. had six churches and four monasteries. Pop. (1870) 11,354.

Ran'dolph, **Earl of Moray**, nephew of Robert the Bruce, first emerges in history on the eve of the battle of Bannockburn (1314), where he routed, with an inferior number of men, Clifford at the head of 800 horse, as he approached Stirling Castle from the east. In 1315, when the order of succession to the throne was adjusted, R. upon certain contingencies was appointed to be guardian of the kingdom. On the 20th September 1319, he fought a battle near Borough Bridge, in Yorkshire, known as the Chapter of Milton, owing to the number of English ecclesiastics who contended with the Scotch spearmen. And again in 1322 he assailed the English, and drove them S. to York. R. travelled to the Papal court at Avignon in 1324, where, says Burton, the rough Scots soldiers overreached the Pope in diplomatic subtlety, and wrung from him the promise that he would henceforth address Robert the Bruce by the title of king. In 1327 he conducted another raid into England, and on the death of King Robert became, under the Act for the settlement of the crown, the Regent. He died July 1332, and, writes Burton, left behind him 'a traditional reputation for even-handed justice and wonderful sagacity.' See Burton's *History of Scotland*, vol. ii.

Ran'dolph, John, of Roanoke, an American politician, born 2d June 1773, at Cawson, Virginia, was of an old and wealthy family, and is said to have been seventh in descent from the famous Pocahontas. He studied at Princeton, and at William and Mary College, but without much application, and afterwards read law at Philadelphia. In 1799 he was elected to Congress, though the celebrated orator, Patrick Henry, opposed his election. With one or two short interruptions he sat in Congress thirty years. He was an ardent republican and follower of Jefferson, yet opposed the war with England in 1812 and the Missouri compromise in 1820. His sarcastic eloquence always excited attention, but gained him few friends, and in 1826 he fought a duel with Henry Clay. In 1822 and again in 1824 he visited England, and in 1830 he was appointed Minister to Russia, but spent most of his time in London, and returned in 1831. His nervous eccentricities, which extended even to dress, attracted much attention in England. He died at Philadelphia, 24th June 1833, leaving a will by which he emancipated his slaves, and provided for their maintenance. This will afterwards gave rise to much litigation. See *Biography of J. R.*, by Sawyer (New York, 1844). *Life of J. R.*, by Garland (New York, 1850), and Powhatan Bouldin's *Home Reminiscences of J. R.* (Richm. 1878), a work which has all the charm of picturesque detail.

Ran'dolph, Thomas, an English poet, was born at Newnham, Northamptonshire, in 1605. Educated at Westminster School along with Mayne, he proceeded to Trinity College Cambridge, where he took the degree of M.A., and obtained a fellowship. Ben Jonson made a bosom friend of him. He wrote several lively dramas entitled *Aristippus*, *The Muse's Looking-Glass* (1630), *The Conceited Pedlar*, *The Jealous Lovers* (1632), *Amynias* (1638), and *Hey for Honesty*. Several of the songs scattered through these works—as much masques as set plays—are spirited and graceful. R. led a life of dissipation, and died 17th March 1635. His *Dramatic Works* were edited by W. C. Hazlitt in 1875.

Raneegunge (Raniganj, 'Queen's market'), a town in the district of Burdwan, Bengal, British India, on the left bank of the Dahmudah River, 120 miles N.W. of Calcutta by rail. Pop. (1872) 19,578. It is celebrated as the spot where coal and iron have been first profitably worked in India. The R. coalfield has an area of 500 sq. miles; the seams are numerous, and those that are now worked vary in thickness from $4\frac{1}{2}$ to 35 feet. Coal was worked here as early as 1777. In 1872 there were 44 collieries, with a total output of 322,443 tons, most of which was sent to Calcutta or used on the railway. The largest concerns are at Chowkidanga, R. itself, Seaisol, and Jemery. Iron ore is found abundantly in clay beds and magnetic deposits. A large European company, established in 1875, has achieved some success in setting up blast furnaces on the European model. In 1876-77 the registered exports of coal to Calcutta were 254,000 tons, valued at £356,000. The imports by rail included £135,000 of salt, and £113,000 of piece-goods.

Range, in gunnery, is the distance from the gun at which the projectile strikes the earth. This distance depends upon the angle of projection, the initial velocity of the projectile, and the resistance offered by the air to its flight. Were there no resistance, the trajectory would be a parabola, and the maximum R. for a given initial velocity would be obtained when the angle of projection was 45° . The resistance of the air, however, completely alters the form of the trajectory; and for high initial velocities, the angle of projection for maximum R. is about 32° . Elongated projectiles travel much further than round shot; and as great a R. as 6 $\frac{1}{2}$ miles has been covered by a 250-lb. projectile fired from a Whitworth gun at an angle of 33° .

Rangoon ('the city of victory'), the capital of British Burmah, and the chief town of the district of the same name, lies on the left bank of one of the twelve mouths of the Irrawaddy, known as the R. River, about 25 miles above the sea, and 62 miles S. of the ancient capital of Pegu. Pop. (1876) 108,000. It was originally built in 1753 by Alompra, the founder of the Burmese monarchy. In 1824 it was occupied by the British during the First Burmese War, and again in 1852 it was captured by storm in the Second War, the result of which was the annexation of the province of Pegu. It contains few important buildings beyond the administrative and commercial offices. It is,

however, celebrated for the great Shoay-dagon pagoda, situated on an eminence 800 feet square, which formed a strong citadel during the last siege, and which has lately been strongly fortified. The superstructure of this building cannot be very ancient; but in massiveness and ornamentation it is unsurpassed, as also for sanctity, as it contains relics of the great Buddha Gautama and his three immediate predecessors. It was regilded in 1870 at a cost of £60,000, and a new Htee or top, presented by the King of Burmah, costing £65,000, was placed on it. Other conspicuous buildings are the barracks for European troops, and the central jail, in which are usually confined some state prisoners from India. The municipality was organised in 1874, being half composed of non-official members. In the first year, the municipal income was £43,000, and a large amount was expended on sanitation, &c. R. is in weekly communication with Calcutta by the British Indian line of steamers, and is by far the most important port in the province. In 1874-75, including coasting trade, the total exports were valued at £3,826,000, chiefly rice and timber; the imports at £3,959,000, comprising betel nuts, salt, piece-goods, cotton twist, crockery, raw silk, wines, and liquors; 838 vessels entered the port, with a total tonnage of 565,000. The exports of rice, which showed a great decrease on the previous year, were 389,900 tons, valued at £1,769,000, more than half of the total from all Burmah. In the same year there passed through the custom-house goods valued at £600,000, going up the river to Independent Burmah, on which a duty of only 1 per cent. is levied. The manufactures are chiefly confined to mills worked by steam for the husking of rice. R. is already the third city in commercial importance in the Indian Empire, and lying as it does at the mouth of the Irrawaddy, navigable for at least 1200 miles, it will undoubtedly become in time a great city. It has been laid out with this view, and the spacious site between the R. and Pegu Rivers, with the Poosondong River flowing through it, will hold a vast population.—The district of R., which lies E. of the Irrawaddy River, has an area of 9800 sq. miles; pop. (1872) 431,069. Almost the entire cultivated area, 1100 sq. miles, is under rice. A railway has recently been constructed up the river to Promé, a distance of 150 miles. See General Fytche's *Burma, Past and Present* (Lond. 1878).

Rank, the relative position in which officers and men stand in the army and navy. *Army R.* is the position held by an officer in the army by brevet or through his status in his regiment, and his seniority in that R. is determined by the date of his commission. If the commissions of two officers bear the same date, their relative seniority remains as it stood before their promotion in the R. below. *Brevet R.* is a superior R. in the army to that attained by an officer in his regiment, and is given for long service, or as a reward for gallant conduct. In his regiment an officer ranks according to his regimental title, but stands among other officers in the army according to his brevet R. Officers in the Grenadier, Coldstream, and Scots Guards hold higher R. in the army than the nominal R. in their regiments. *Local R.* is a higher R. assigned, within particular limits, to officers serving abroad, in order that they may take proper position among officers of other troops, or that they may be enabled to perform more important duties. *Honorary R.* is such R. as is given (usually a step in advance) to officers retiring on full pay, but it is not accompanied by increased pay. *Substantive or permanent R.* is R. where the pay of the officer corresponds to it, and up to the post of captain is the only R. which obtains in the army. Among non-commissioned officers and men the positions of regimental corporal-major, regimental sergeant-major, quartermaster corporal-major, regimental quartermaster-sergeant, sergeant, corporal, bombardier, second corporal, and private, are ranks; all other positions being appointments. In the navy there is only one kind of R. for all officers. For the relative R. of army and navy officers, see RELATIVE RANK. See also PROMOTION.

Rank and File. All soldiers bearing arms, from corporals downwards, are designated as the R. and F. of the army. A line of soldiers standing side by side is called a *rank*; a line where the men stand behind one another is called a *file*. The term R. and F. is thus meant to include the entire mass of a body of troops.

Rank's, Leopold von, born at Wiehe in Thüringen, December 21, 1795, was educated at Donndorf and Schulpforta,

next studied at Leipzig, and in 1818 became head-master of the gymnasium at Frankfurt-am-Oder. Two works both published in 1824, *Geschichte der Romanischen und Germanischen Völker von 1494-1534* and *Zur Kritik neuerer Geschichtschreiber*, at once proclaimed their author's ability, and gained him a chair of History at Berlin. Here R. soon signalled himself as an author, lecturer, and founder of an historical school. In 1827, shortly after the appearance of his *Fürsten und Völker von Südeuropa im 16. und 17. Jahrhundert* (4th ed. 1857), he undertook, at the cost of the Prussian Government, a journey to consult the Austrian and Italian archives. Those of Venice proved especially valuable, and on them he drew largely for the materials of his *Serbische Revolution* (1829; Eng. trans. 1853), *Die Verschwörung gegen Venedig im Jahre 1688* (1831), and *Vorlesungen zur Geschichte der Italienischen Poesie* (1837). Important as these works are, they were eclipsed by *Die Römischen Papste, ihre Kirche, und ihr Staat* (3 vols. 1834-37; 5th ed. 1866-67; Eng. trans. by Kelly, 3 vols. 1843, and E. Foster, 1847), and *Die Deutsche Geschichte im Zeitalter der Reformation* (6 vols. 1839-47; 4th ed. 1867; Eng. trans. by Sarah Austin, 3 vols. 1845-47). Appointed historiographer of the Prussian kingdom in 1841, R. now produced *Neun Bücher Preussischer Geschichte* (3 vols. 1847-48; Eng. trans. by Sir A. Duff Gordon, 1849), which, with its freedom from national bias and vainglory, was coldly received. In France, however, his *Französische Geschichte, vornehmlich im 16. und 17. Jahrhundert* (5 vols. 1852-61; 2d ed. 1857-62) is a standard authority, whilst his *Englische Geschichte, vornehmlich im 17. Jahrhundert* (6 vols. 1859-67; 4th ed. 1877; Eng. trans. Oxf. Clar. Press, 1875) is allowed by common consent to clear up much that Hallam and Macaulay left obscure. Amongst R.'s minor, though only relatively minor works, may be reckoned his *Geschichte Wallensteins* (1869), *Die Deutschen Mächte und der Fürstenbund* (2 vols. 1871-72), *Genesis des Preussischen Staates* (1873), *Ursprung und Beginn der Revolutionskriege 1791 bis 1792* (1875), *Friedrich der Grosse, Friedrich Wilhelm IV., zwei Biographien* (1877), and *Denkwürdigkeiten des Staatskanzlers Fürsten von Hardenberg* (4 vols. 1877). Since 1867 he has been bringing out a complete edition of his works, of which 39 volumes have at present appeared. No historian has grasped European politics so widely and so firmly as R. In the internal working of foreign constitutions he is necessarily sometimes at fault, confounding, for instance, an impeachment with a bill of attainder; but such occasional slips are far outweighed by his masterly survey, based on contemporary documents, of England's connection with the Continent under the Stuart dynasty. His style is characterised by its intense seriousness, history being to him neither romance nor epic, and by an objectivity rarely met with amongst his countrymen.—His brother, **Karl Ferdinand R.**, born at Wiehe, May 26, 1802, was successively director of the gymnasiums of Quedlinburg (1831), Göttingen (1837), and Berlin (1842), and died in the last-named city, March 29, 1876. He was author of a *Chrestomathie aus Lateinischen Dichtern* (5th ed. 1873), *Lives of Aristophanes* (2d ed. 1845) and *Sophocles* (1876), *Rückerrinnerungen an Schulförta* (1874), &c.

Ranking and Sale is a complete and comprehensive process of Scotch law, by which the heritable, or real, property of an insolvent person is judicially sold, and the price divided among his creditors according to their several rights and preferences.

Rank'ness is a certain condition assumed by plants arising from excessive richness of soil, or too free an application of manure. Grasses become coarse and unpalatable; shrubs and fruit trees produce luxuriant shoots with a minimum of fruit-bearing wood, and it becomes necessary to check this unprofitable overgrowth by pruning. In all cases the tendency of R. is to diminish the fruit yield of the plant, and to produce an abundance of roots and suckers. Some plants, however, have naturally such a surplussage of luxuriance that for practical service it has to be modified—thus the pear is frequently grafted upon the stock of the quince to accomplish this. See PRUNING.

Rann'och, Loch, a Scottish lake in the N.W. of Perthshire, and to the N.E. of the wild, wide moor of the same name. It is 11 miles long and nowhere more than 2 broad, receives the Gauer water from Loch Lydoch, and the Erich from the loch of that name, and sends forth the Tummel to join the Tay 3 miles above Pitlochry. It is girt by mountains, partly covered with birch woods, and its waters abound with trout and char.

Ran'ula is the term applied to an encysted tumour, very analogous to a ganglion, found in the floor of the mouth and raising up the tongue. R. resembles the body of a frog, hence its name. It may be caused by the obstruction of one of the large salivary ducts by a calculus, by the expansion of one of the processes of a salivary gland, or by the formation of a cyst in the cellular tissue. R. may be cured by making a free incision into it, pressing all the fluid out, and keeping the wound open till the cavity has filled up; or a portion of the cyst may be snipped out with the scissors, or a seton may be passed through it.

Ranuncula'ceæ is a natural order of thalamifloral dicotyledons—forming the opening order in works arranged according to the system of De Candolle—and consists of about 500 species of annual or perennial herbs, or rarely shrubs, found abundantly in temperate and cold regions of the world. It is founded upon the common crowfoot or buttercup, but embraces plants of very different structure within its limits. Its essential characters are indefinite stamens, anthers attached by their base and opening by slits, and albuminous seeds. The properties are acrid and poisonous—sometimes vehemently so, as in aconite and hellebore. Some of its constituents are beautiful with gay flowers, as the peony, ranunculus, larkspur, and columbine, while many are mere weeds. In larkspur and aconite the general resemblance to the regular portion of the order is much obscured, from the striking variation and irregularity in the calyx and corolla.

Ranun'culus (from Lat. *rana*, 'a frog') is the type genus of *Ranunculaceæ*, consisting of about 160 species of herbs found in all temperate regions. The yellow or white flowers are usually paniced; the sepals 3 to 5, caducous, imbricate in bud; the petals usually 5, glandular at the base; the stamens many; the carpels numerous, with a short style, and an ascending single ovule; the fruit a head or spike of apiculate or beaked achenes. The three species commonly known as buttercups (*R. acris*, *R. repens*, and *R. bulbosus*) are familiar representatives of the genus, and the goldilocks of woods and copses (*R. auricomus*), the lesser spearwort of wet places (*R. Flammula*), and the spring-flowering pilewort or lesser celandine (*R. Ficaria*) of damp, shady situations, are all common plants. The greater spearwort (*R. Lingua*) with handsome deep-yellow flowers as big as a crown-piece, is more local, whilst the celery-leaved R. (*R. sceleratus*) is common in watery places, but has inconspicuous flowers; it is very acrid. *R. arvensis*, with achenes beset with hooked prickles, is a noxious cornfield weed. A section of the genus called *Batrachium* embraces a very variable and puzzling series of aquatics, common in ditches, ponds, and streams. They usually bear white flowers, and produce two kinds of leaves, those upon the surface being more or less circular, whilst the submerged are cut into numerous capillary or linear segments. Among cultivated species *R. Asiaticus* affords the endless varieties of the R. grown by florists—varying both in doubleness and colour; and *R. aconitifolius* is the 'white bachelor's buttons' of gardens, a double variety of *R. acris* forming the yellow. None of the species have any noteworthy economic properties or uses.

Ranunculus Lingua.

Ranz des Vaches, the name given to the simple melodies played by the herdsmen of the Swiss Alps on the Kuh-horn (q. v.) when driving the cattle to arid from their pasture grounds. They have been collected and published along with other popular Swiss melodies in the *Sammlung von Schweizer Kuhreigen und Volkslieder* (Bein, 1818), and in the *Allgemeine Schweizer Liederbuch* (1851).

Rapall'o (formerly called Tigulia), a seaport of N. Italy, in the province of Genoa, 19½ miles E. by S. of that city by rail. In the vicinity is the pilgrimage church of the Madonna di Mont-

allegro. R. has an active coral fishery, and considerable trade in olive-oil, besides manufactures of soap and wax. Pop. (1874) 5352.

Rape (from Lat. *rapio*, 'I seize') is the crime of having carnal intercourse with a woman by force, and against her will. Penal servitude for life, or minor punishment, may be awarded to the offender, according to circumstances. The injured woman is an admissible witness to prove the crime; but the value of her evidence is a question for the jury, depending on such questions as—Is she of good character? Did she immediately tell of her injury to some one, and cause search to be made for the offender? It is an essential feature of the crime that it be against the will of the sufferer, so that if she be cheated into consent the crime is not committed; but the guilt is not extenuated by showing that the woman yielded to threat of murder, or of even minor violence. All aiding or abetting in this crime are equally guilty with the chief perpetrator. See ABDUCTION.

Rape or Cole Seed, is the *Brassica Napus* of Linnæus, one of the factors of the puzzling series that Dr. Boswell combines under the significant name of *B. polymorpha*. It is either annual (*B. praxos* of some writers) or biennial, and is distinguished from its allies *B. Rapa* and *B. campestris* (the source of the turnip group) by its fusiform root, its leaves all being glabrous and glaucous, and its corymb lengthening before the fall of the deciduous petals. The plant has a wide distribution through Europe and temperate and sub-tropical Asia, appearing also in a quasi-synchronous condition in Britain; but it is impossible to distinguish in what countries it is truly wild, and where it is merely an escape from or remnant of cultivation. The two principal reasons for which it is grown are for the feeding of sheep upon the stalks and leaves, and for the extraction of oil from its seeds. For these purposes it is largely cultivated in Europe, and for a long period has been grown in the eastern and southern counties of England. The plant delights in a rich alluvial soil, and is one of the few suitable for newly reclaimed bog and fen land. Great crops have been produced in the fens of Lincolnshire and the alluvial flats of Essex. R. speedily, however, exhausts the soil, and some leases prohibit its cultivation, except to be eaten green by sheep. The collection of the seed is somewhat precarious, as the lower pods are ready to burst before those at the top are full. If the season is wet at harvest, much of the seed is lost, and without great attention some loss is sustained in the most favourable seasons. The plant should be cut when the dew is on it, and removed as little as possible; indeed, if the weather permits, it is advisable to thresh out the seed on a cloth in the field. The seed is subsequently spread out on the floor of a granary that it may not heat, and is turned frequently over until it is ready to go to the crushers, who express the oil. The residue after pressure forms R.-cake, sometimes used as a cattle food, but generally ground up and used as a manure.

Raphael, Sanzio da Urbino, among painters 'the divine,' and the 'Phœbean singer' of the Renaissance, was born at Urbino, 28th March 1483. Descended of a family which had produced several artists and ecclesiastics, his father, Giovanni Sanzio or de Santi, himself an artist standing high in the second rank of the Umbrian school, instructed the young R. in the rudiments of art. On his father's death in 1494 R. entered the school of Pietro Perugino at Perugia, where he remained till about his twentieth year. Of the works painted by him before 1495 nothing is known with certainty, and he now acquired Perugino's manner so perfectly that the works of this period are only distinguished from that master's by their great freedom, elaboration, and delicacy. R. spent the summer of 1502 in Siena, where, to assist Pinturicchio in adorning the cathedral library, he made some designs, two of which are still preserved, one at Florence, the other at Perugia. Not later than 1503 were painted the exquisite little 'Madonna between S. Jerome and S. Francis,' now in the Berlin Museum, the beautiful 'Staffa Madonna,' which remained in the Staffa Palace, Perugia, till it was sold for £14,000 to the Czar in 1871, and the allegorical 'Knight's Dream,' now in the National Gallery, besides several other easel pictures. The 'Sposalizio,' or 'Espousal of the Virgin' (1504), is the most celebrated example of R.'s first or Peruginian style. It preserves the simplicity and tenderness, with not a little of the constraint, of the Umbrian school, while the figures are invested with a new dignity, and the features are lit with a subtler, sweeter intelligence. R. proceeded in October 1504 to Florence, then

the glorious centre of the Cinquecento revival, and the art treasure-house of N. Italy. In the City of the Lilies, a knowledge of the grander methods and heroic aspirations of Florentine art burst upon the disciple of quietism, and severed the bonds of Umbrian conventionality. R. now studied the nature-breathing frescoes of Masaccio in the Brancacci Chapel, and drank inspiration from the precious antiques garnered by Lorenzo de Medici in the gardens of San Marco. The cartoons of Leonardo and Michael Angelo filled his mind with nobler ideas of form and composition, while to the devout Fra Bartolommeo, himself educated by the influence of Leonardo, he owed more, perhaps, than to any other teacher. Among the most interesting works of this period are the Uffizi portrait of himself, in which he shows a pale, eloquent face, with brown hair and eyes; the charming 'Three Graces,' his first classical theme; 'La Belle Jardinière' (said by Clement to be so called because the model was a fair flower-girl), in whom are so exquisitely blended divine beauty and human feeling; and the majestic 'Entombment of Christ,' the chief ornament of the Borghese Palace. These works indicate a rapid transition from the still, statuesque expression and stately mysticism of the Umbrian style to the dramatic movement, vivid realism, and glowing colour which found their consummate utterance in the *Stanza* and *Galatea*. In the complete second or Florentine style the Madonna is no longer a pallid, nun-like abstraction, but a noble type of human beauty, who seems 'to look on Jesus as her beloved child rather than as her divine Lord.' Without losing his earlier purity and elevation, R. has now gained in vitality and force of treatment something of the intense power of Angelo, and in varied choice of theme and plenitude of resource not a little of Leonardo's versatility. At the age of twenty-five, and when Leonardo was fifty and Angelo thirty-three, R. went by invitation to the court of Pope Julius II., where he was commissioned to fresco the Vatican hall of judicial assembly called 'La Segnatura,' one of the four halls of *Le Stanze* which had already been decorated by Perugino, Francesco, and others. On the walls of this room he painted with his own hand (1508-11) a pictorial epic in four magnificent allegories—Theology, Philosophy, Jurisprudence, and Poetry. These mark the highest reach of the master's art in solemn grandeur of conception, calm realisation of the loftiest ideal by perfect harmony in grouping, colouring, and draping, and above all in the bold and successful translation of 'the golden treasure of the Christian spirit into the silver vessel of antiquity.' Delighted with the transformation of *La Segnatura*, the Pope ordered that the frescoes in the other rooms of *Le Stanze* should make way for fresh creations of the new favourite. But R. subsequently preserved an entire vault by Perugino, and several small works of Sodoma. Meantime the Sistine frescoes of Angelo were publicly unveiled (1512), and of these R. made a careful study. The Madonnas of the Roman period are stronger and grander than those painted at Florence, and this is ascribed by Lanzi and Mengs mainly to an earnest study of the newly-discovered antiques. The second hall of the Vatican was decorated (1512-14) with 'The Miraculous Expulsion of Heliodorus from the Temple,' 'The Miracle of Bolsena,' 'Attila Repulsed from Rome,' and 'The Deliverance of St. Peter.' These works indicate perhaps his nearest approach as a colourist to the Venetian school, while they show an increase of freedom and flexibility, of dramatic power, and of skill in handling large masses of light and shade, and at the same time a tendency to that coarseness of execution which becomes more visible in the later frescoes. The frescoes in the third of the *Stanze*, including 'The Fire in the Borgo,' 'The Oath of Leo III.,' 'The Coronation of Karl the Great,' and 'The Victory of Leo IV. over the Saracens at Ostia,' were painted partly by his pupils (1514-17) and from his designs. They are dedicated to the glory of the Papal power. Those in the Sala di Constantino, representing scenes from the life of Constantine the Great, were executed from his drawings (1519-24), under the direction of Giulio Romano. The frescoes of the Loggia (galleries) in the Vatican were designed by R. (1514-16), and comprise the series of exquisitely simple compositions, upwards of fifty in number, known as 'R.'s Bible.' For Leo X., R. designed (1515-16) the famous cartoons for the ten tapestries, worked at Arras, and still preserved in the Vatican. The seven cartoons, now after many vicissitudes safe in South Kensington Museum, have been frequently engraved, and are preferred by some judges to any other of R.'s works. The subjects are drawn from the Acts of the Apostles, and the splendid series

is called by Quatremère de Quincy 'the climax not only of the productions of R., but of all those of modern genius in painting.' R. had already executed the 'Sibyls' for Santa Maria della Pace, which for serenity and grace far outvie the sublime 'Sibyls' of Angelo, and the incomparable 'Triumph of Galatea' in the Chigi Palace. In rapid succession followed the 'Birth of Venus,' 'Madonna della Sedia,' 'Christ Bearing the Cross' ('Lo Spasimo'), 'The Visitation,' 'The Archangel Michael,' 'The Large Holy Family of the Louvre,' the portraits of Leo X. and Joanna of Arragon, 'The Violin-Player,' 'The Sistine Madonna' (Dresden), and 'The Transfiguration.' Symonds calls the Sistine Madonna the 'sublimest lyric of the art of Catholicity.' According to Passavant, together with the 'Transfiguration,' it has 'excited the most constant admiration and the warmest veneration throughout all Christendom.' These were the last works of the master, who, having caught malarial fever, died on Good Friday, April 6, 1520. Short as was his career, the vast mass of his work is not less striking than its variety. His easel-pictures crowd the galleries and palaces of Europe, and yet he produced innumerable designs never used for painting, was himself a sculptor, engraver, and sonneteer, and still found time, from 1514, to superintend the building of St. Peter's, and to form an elaborate plan for the excavation of Rome. Gifted with an industry equal to his fertility, in the wide range of his labour there is everywhere visible a perfect serene equipoise between the faculty of the artist and the artistic purpose. 'There is nothing overmuch in any portion of his work, no sense of effort, no straining of a situation, not even that element of terror needful to the true sublime.' Viewing the world through a pure atmosphere of joy and beauty, R. threw a tinge of loveliness even over tragedy and death, while he shrank from a realistic treatment of what was stern or shocking. His dictum that 'we must not represent things as they be, but as they should be,' has been spurned by modern pre-Raphaelites, and Ruskin says that on the walls of the Segnatura the artist 'wrote the *Mene Tekel Upharsin* of the art of Christianity.' But this Hellenic tendency to glorify flesh and feeling, to scout ugliness and obscenity, and to dower youth with beauty and old age with dignity, is that which makes R. peculiarly the singer of the Renaissance. Lanzi likens the rivalry of R. and Angelo to that between Zeuxis and Parrhasius in its stimulating both to their highest efforts. R. in his later years lived like a prince, owned a palace in Rome and a villa beyond the walls, and was surrounded by a retinue of disciples. He left property to the value of sixteen thousand ducats, and bequeathed his painting materials to his favourite pupils, Giulio Romano and Gianfrancesco Penni. See the biographies of R. by Vasari, Quatremère de Quincy, Von Woltzen, Charles Blanc, Charles Clement, C. P. Landor, and especially that by Passavant (Paul Lacroix's ed. Par. 1860); the art-histories of Lanzi, Kugler, Layard, Jameson, Crowe and Cavalcaselle, Rosini, and Symonds; also Gruyer's voluminous works on the Madonnas, and Heri Ruland's exhaustive catalogue of the works (Lond. 1877).

Rapha'nia, or **Er'gotism**. See **ERGOT**.

Raph'ides (Gr. *raphis*, 'a needle'), are acicular crystals of calcium oxalate found disposed in bundles in the cells of plants. They abound in some genera, such as the Cacti, and many of the Lily family, and in the medicinal 'Turkey rhubarb' their presence imparts the peculiar grittiness, 100 grains of the root containing 30 or 40 grains of the crystals. In the duck-weeds their presence or absence furnishes a specific character. R. vary in size, from $\frac{1}{16}$ to $\frac{1}{8}$ of an inch in length. In some plants, as geranium and pelargonium, in which they are abundant, they have a radiating arrangement.

* Rapier Hilt.

Rap'idan. See **RAPPAHANNOCK**.

Rap'ier (Ger. *rapier*, 'a foil,' Fr. *rapière*), a sword having a straight, thin, narrow blade, generally four-sided, designedly for thrusting only. From Italy the R. was carried into France and Spain, and in the 16th c. it was introduced into

England. It was customary for all gentlemen to wear one.

Gallants rivalled each other in the length of their rapiers, till Elizabeth proclaimed that no blade should exceed a yard in length. Toledo, Seville, and Solingen were the most celebrated seats of the manufacture of R. blades. The R. has a cup-guard, frequently richly ornate, a straight handle, and curved or straight *quillons*. The R. was formerly the universal weapon used in duelling and fencing.

Rapin, de Thoyras, Paul, a French historian, was born 25th March 1661, at Castres in Languedoc, studied at the Protestant Academy of Saumur, became an advocate in 1679, preferred a military life, but was kept from it by his father's advice, and in consequence devoted himself to music, mathematics, and ancient literature. In 1686 he crossed to England, from whence he passed to Holland to join a company of cadets at Utrecht, recrossing in 1689 in the train of William of Orange, whom he served in Ireland, receiving a severe wound at the siege of Limerick. By 1693 he had become a captain, and was appointed travelling tutor to the son of the Earl of Portland. In 1699 he married, and in 1707 retired to Wesel, where he devoted himself with untiring zeal to the production of his *Histoire d'Angleterre*, published at the Hague (8 vols. 1724; Eng. trans. by Tindal, 15 vols. 1725-31; 2d ed. 1733). It traverses the ground from the Roman invasion to the death of Charles I., and has a fine enthusiasm for political liberty, besides being lucid and orderly in its narrative and rich in matter. R. had previously written a curious *Dissertation sur les Whigs et les Tories*. He died at Wesel, 16th May 1725.

Rapp, Jean, Comte, born at Kolmar, April 27, 1773, was destined by his father for the Church, but (1788) entered the army, and having distinguished himself under the eye of General Desaix at the battle of Szeiskam, was appointed his aide-de-camp. After the battle of Marengo he acted in the same capacity to Napoleon, who made him a general of division (1805) on witnessing his conduct at Austerlitz. His behaviour in Prussia and Poland gained him the surname of 'the intrepid.' For his services at the battle of Lobau (August 1809) he was made a Count of the Empire. He played a brilliant and glorious part in the Russian expedition, in which he was wounded for the twenty-second time, and specially signalised himself by his heroic defence of Danzig against the Russians. Forced to capitulate, he was sent to Russia as a prisoner, and only released on the return of the Bourbons in 1814. During 'the Hundred Days' he joined Napoleon and got command of the army of the Rhine, and was created a peer of France. Until 1817 he lived in Switzerland, but being pardoned his allegiance to his old master, he entered Louis's service as king's chamberlain, and died at Paris, 8th November 1821. His *Mémoires* (from family papers) were published in 1823. In 1853 a bronze statue was erected to his memory in his native town. See De Courcelles, *Histoire des Généraux Français*.

Rappahann'ock, a river of Virginia, U.S., rises in the Blue Ridge of the Alleghamies, and after a S.E. course of 250 miles, generally parallel to that of the Potomac, reaches Chesapeake Bay through a broad estuary 70 miles long. The largest affluent is the Rapidan, which joins it 10 miles above Fredericksburg. At the rapids here a fine dam has been made, giving great water-power. Below this point it is a noble tidal stream with important shipping, and for 35 miles above it has been made navigable by artificial means.

Rappee', a moist coarse variety of snuff, which is said to derive its name from the French *rape*, 'a grater,' the instrument originally employed in its preparation.

Rapto'res, an order of birds, sometimes known by the name *Accipitres* (q. v.), and which includes the familiar 'birds of prey,' such as the eagles, hawks, falcons, vultures, owls, &c. They are *monogamous*, and the females are, as a rule, larger than the males. The order has been arbitrarily divided into the *Diurnal* and *Nocturnal* R.

Ras (Heb. *rosh*), an Arabic word meaning 'headland,' and of frequent occurrence in the names of capes on the coasts of Arabia and N. Africa. Its resemblance to the Gaelic *ross*, which has the same signification, is probably accidental.

Rash'es, or **Exanthemata**. See **EXANTHEMATA**.

Rash'i, one of the ablest and most famous of the Rabbis, was born at Troyes in France in 1040. His family name was Ishak,

and from the initials of his full title, Rabbi Shelomo Ishak, was formed the name R. His father was a learned Talmudist, and in the Talmud 'R. was nourished, lived, and moved.' Marrying according to its prescriptions at the age of eighteen, he yet left his home to pursue his studies in the great rabbinical schools of Mainz, Worms, and Speier, undergoing the severest privations, and never seeing his wife except at festival times. In 1064, already a renowned master in the Talmud, he settled permanently at Troyes, where he became the Rabbi of the community, receiving of course no pay for this, and presenting to his contemporaries, till his death in 1105, the perfect example of a Rabbi, of which all Jewish posterity, too, has regarded him as the stainless ideal, expressing its admiration in extravagant legends. His great work was a commentary on a great part of the Talmud, which Grätz considers a model. It is simple, luminous, acute, independent, and many-sided. The language, which is the Talmudic idiom, is at once laconic and perspicuous; indeed, R. is an artist as well as a commentator. With justice, he and his contemporary, Isaac al Alfasi, are regarded as the men who first gave elevation and depth to Talmudic study. Nor is he less original and intelligent in his exposition of most of the books of Scripture. He would know nothing of a mystical explanation or method, and his commentary has been with the Jews the most popular of all such works. See Grätz, *Geschichte der Juden*.

Rask, Rasmus Christian, a great Danish philologist, was born 22d November 1787 at Brændekilde, near Odense in Fyen. In 1807 he left Odense School for Copenhagen University, where in 1818 he became a titular, and in 1825 an extraordinary professor of the history of literature, in 1829 was appointed librarian, and in 1831 extraordinary professor of Oriental languages. After accompanying Nyerup to Sweden and Norway (1812), he went to Iceland (1813-15), and in 1816 began a linguistic tour, at the expense of the Danish Government, through Sweden, Finland, Russia, Persia, and India, from which he returned to Copenhagen in 1823, bringing two collections, the one of Zend and Pehlevi MSS. for the University library, the other of Pali and Singhalese MSS. on palm-leaves for the Royal library. R. died of consumption, 14th November 1832. His chief works are *Veiledning til det Islandske* (Copen. 1811), *Biørn Haldorsens islandske Lexicon* (ib. 1814), *Angelsaxisk Sproglaere* (ib. 1817), *Det islandske Sprogs Oprindelse, Anvisning til Islandskan, Snorra Edda, and Edda Semundar* (ib. 1818), *Synishorn* (ib. 1819), *Singalesisk Skrifflære* (Colombo, 1821). After his return from India he published Spanish (1824), Frisian (1825), Danish (1826), and Italian (1827) Grammars; a *Grammar of the Danish Language* for Englishmen (1830); *Loemau Fabula* (1831); and in 1832 Grammars of old Norse, Lappish, and English, and *Nonnulla de plen systemate Sibilantium in linguis montanis*. After R.'s death his brother brought out his *Samlæde Afhandlinger*, with a life by N. M. Petersen (3 vols. 1834-38). A prodigious memory, joined to great acuteness and accuracy of mind, constantly employed in the severest study, enabled R. to rise to a place in the first rank of the philologists of his century. At his death he was acquainted with 55 different languages. He was the first to reduce philology to a system, and the classification of languages which he already attempted in 1819 is essentially that accepted at the present day.

Raskol'niki (Russ. 'separatists,' from *raskól*, 'schism'—*ras*, 'asunder,' and *kól*, 'to split'), the Nonconformists of Russia, the descendants of the conservative dissenters who parted from the official 'Orthodox' Church in the 17th c. On the introduction of printing, the patriarch Nikon thought it necessary (1654) to choose the best texts of the Liturgy, Psalter, and other religious books, but large sections of the people, believing these 'Nikonian novelties' to be heretical, refused to give up their old Icons and missals, or correct the irregularities of their ceremonial. Persecution (1666) only confirmed their zeal. Thousands fled to neighbouring countries, or to retreats in the northern forests. Peter the Great was to them no other than Antichrist, for had he not eaten and drunk with heretics, and worn their dress, and 'numbered the people;' introduced passports bearing 'the seal of Antichrist,' disfigured 'the image of God' by shaving, and 'destroyed the years of our Lord' by transferring New Year's Day from September to January? After quelling all armed opposition, Peter had recourse to clemency, and issued ukazes (1714) tolerating the R., provided they paid a double poll-tax.

Catherine II. abolished their disabilities (1762), and thenceforth the R. have been generally tolerated, on the condition of paying a certain tax to the parish clergy of the established Church, and to the police. The two main sections of the R. are the *Sitro-odriddsi*, or 'Old Ritualists,' and the *Bezpoposti*, or 'People without Priests' (*bez popsf*), and include (according to Mackenzie Wallace) 7,000,000 people. The latest official census (1871) admits only 1,093,452 R. The Old Ritualists, believing that priests could only be consecrated by bishops, were thus till 1844, when Ambrose, the deposed Metropolitan of Servia, was permitted by Austria to found a bishopric at Bělava Krinitza, in Galicia, forced to accept priests who had seceded from the 'Orthodox' Church. The Priestless People included the Pomórtsi ('dwellers near the coast') and the Theodosians (followers of a sectary Theodosi), and at first believed in celibacy; but a numerous 'orphan' class having arisen among them, they instituted a form of marriage, which the civil power did not recognise till October 1874. The other nonconformists are either *Philippins* (q. v.) *Stánniki* ('Wanderers'), or *Beguný* ('Fugitives')—who call themselves *Christovye Lyúdi* ('Christ's People')—or belong to minor denominations (*tókti*) differing on minor tenets. The dissenters of Russia are about 10,000,000 in all, or one-eighth of the population of the empire, and include in their ranks the third and wealthiest part of the merchant class, the majority of the Don Cossacks, and all the Cossacks of the Ural. See Nilski, *Seménaya zhizn v russkom Raskólé* (St. Peters. 1869); *Select Sermons* by Philaret, late Metropolitan of Moscow (Lond. 1870); Subbótin, *Istoria Bélokrinitzskoi Ierarkhii* (Moscow 1874); Mackenzie Wallace's *Russia* (vol. ii. Lond. 1877).

Rasores. See GALLINACEOUS BIRDS.

Rasp, a species of file having distinct abrading prominences formed by indentations of a pointed punch, instead of with a chisel, as is the case with a file. The R. is almost exclusively used for operating on wood, bone, and the softer metals.

Raspail, François-Vincent, chemist and politician, was born at Carpentras, January 29, 1794, where he received his education from a priest. He was sent to Avignon to complete his education, and in 1811-12 he delivered lectures on theology and philosophy, but declined to enter the Church. In 1816 he went to Paris, took various scholastic engagements, studied law and natural science, and between 1827 and 1830 made many important contributions to organic chemistry in the *Annales des Sciences Naturelles* and the *Bulletin des Sciences*. Into the Revolution of 1830 R. threw himself with great impetuosity on the democratic side, and received a severe wound. He was then offered the administration of the Museum of Natural History, but declined it. In 1831, for a violent letter in *La Tribune*, he received fifteen months' imprisonment, and, with the exception of brief intervals, he continued in custody until 1836, because of his outspoken hatred of royalty. But his scientific studies were prosecuted with unabated fervour. In 1843 he began to develop his theory of disease, and to advocate the antiseptic virtues of camphor. He even prosecuted a lucrative practice, until he was stopped on the ground of illegality. He was one of the leaders of the Revolution of 1848, and exercised a great influence by his writings in *L'Ami du Peuple* and his speeches in the clubs. In 1849, however, for advocating the abolition of the Presidency in offensive language, he was imprisoned for five years, during which time he was twice elected to the Assembly. In 1854 he retired to Belgium, and continued his devotion to science until 1869, when he was elected to the Corps Législatif, where he associated himself with Communism in its most extreme enunciation. After the fall of the Empire he became the idol of democratic Lyon, which returned him regularly as its member. The aged demagogue died at Paris, January 10, 1878, leaving a reputation for consistency and earnestness which, however, bore no fruit to his party on account of the impracticability of his views.

Raspberry (*Rubus Idæus*) is the only species of the extensive genus *Rubus* (q. v.) that has been brought into general cultivation for its fruit. It is a shrub with a perennial rootstock, throwing up suckers which grow into biennial stems (technically *canes*), more or less clothed with slender straight prickles. The leaves are pinnately three to five foliate; the flowers drooping, with white petals; the fruit (which consists of many aggregated drupes) red or yellow and hoary, falling off from the spongy conical receptacle when fully ripe. The R. is common in woods, &c., through Britain, ascending to 2000 feet in the Scotch High-

lands, and has a wide distribution through Europe and Northern and W. Asia. 'It was known to the ancients, and Linnæus retained the classic name of *Ida* with which it was associated by Dioscorides.' The mode of cultivation is by suckers, which are usually planted in rows from N. to S. at 4 feet apart every way. Growth from seed is only resorted to when new varieties are wanted. The fruit of the *R.* ranks in the dessert with the gooseberry and strawberry, but its principal uses are for jams, tarts, sauces, sweetmeats, and ices, and it is employed on a large scale in preparing spirituous liquors and cooling syrups. It is reckoned next in efficiency to the strawberry in removing the tartar of the teeth, and has been recommended to gouty and rheumatic subjects. In Scotland both the *R.* plant and fruit are generally called 'rasps,' and locally the name 'hindberry' is used. The origin of the name *R.* is doubtful. *R. occidentalis*—the black *R.* or 'thimbleberry' of N. America—yields a well-flavoured and large fruit, ripening early; and the value of that of *R. odoratus* would doubtless be enhanced by cultivation. *R. parvifolius* is the native *R.* of Australia.

Rasp'berry Vin'egar is a pleasant acidulous fruity beverage, prepared by bruising up raspberries in an equal proportion of good malt or wine vinegar, allowing the mixture to stand for three days, and then pressing and straining out the juice. To each pint of juice so obtained add 1 lb. of refined cane-sugar, then boil, skim, and bottle immediately the *R. V.* is cool. It is sometimes fortified with a little brandy.

Rasse (*Viverra zibethica*), a species of Carnivorous quadrupeds, inhabiting India and other parts of E. Asia, and allied to the Civet (q. v.). It is about 3 feet in length, is of a general greyish-brown hue, variegated with longitudinal rows of black spots. The tail is long and marked by black rings. Like the civet, the *R.* secretes an odoriferous substance, which is in high repute amongst the Javanese, by whom it is named 'Dedes.'

Ras'tadt, or **Ras'tatt**, a town of the Grand-Duchy of Baden, situated on the river Murg, 3 miles from its junction with the Rhine, and 15 miles S.W. of Karlsruhe. In 1840 it was strongly fortified by the German Confederation, but since the annexation of Strassburg in 1871 its fortifications have been razed. Near it is a palace, formerly the residence of the Margraves of Baden-Baden, built in imitation of Versailles. It has manufactures of tobacco, metal-ware, and papier-maché. Pop. (1875) 12,205. *R.* has been the seat of two congresses. At the first, in 1714, Marshal Villars, on the part of France, and Prince Eugene on that of Austria, signed the peace which concluded the War of the Spanish Succession. The second in 1799 separated without any result having been arrived at, and the three French plenipotentiaries on leaving the town were attacked by Austrian dragoons, who murdered two of them, and seized the papers of the legation.

Rat (*Mus*), the name applied to various species of *Rodents* of the genus *Mus*, which also includes the mice. The two typical species of *R.* are the common or brown *R.* (*Mus domesticus*), and the black *R.* (*Mus rattus*). In England the latter has been well nigh exterminated by the brown *R.* The black *R.* is smaller than the brown *R.*, and the upper jaw is more prominent. The brown *R.* is also termed the 'Norway *R.*,' and the black *R.* the 'English *R.*' The tail of the brown *R.* is shorter relatively to the size of its body than that of the black *R.* Its average size is about 8 or 9 inches. Both species breed several times in the year, and may produce from ten to fourteen or fifteen young at a birth. The skin of the *R.* is largely utilised for the manufacture of glove-leather.

The water *R.* is the Water Vole (*Arvicola amphibius*) of naturalists (see *VOLE*). The Musk *R.* is described in the article of that name. The Coypu *R.* or Racoonda (*Myopotamus coypu*) inhabits Central America. It is allied to the beavers, is aquatic in its habits, and attains a length of about 2 feet 6 inches. The Beaver *R.* (*Hydromys chrysogaster*) is allied to the Musk *R.* It inhabits Van Diemen's Land, and resembles in its habits the Water Vole. The name '*R.*' is applied to Rodentia far removed from the *R.* family (*Muridae*). Thus the Mole *R.* (*Spalax*), Coast *R.* or Land Mole (*Bathyergus*), and the Pouched *R.* (*Sacophorus*), are *R.*-like only in appearance, and have no near affinities with the true rats.

Ratafia, in France, the generic name for liqueurs compounded of alcohol, sugar, and the odoriferous and flavouring

principles of plants; also a spirituous liquor consisting of brandy flavoured with apple or apricot kernels.

Ratch'et is a stop or detent which drops into the spaces between the teeth of a wheel, called a *R.-wheel*, rising as the wheel moves forward, but preventing it from moving backwards.

Ra'tel (*Mellivora R.*), a species of Carnivorous animal allied to the Weasel (q. v.), and known also as the 'honey weasel' and 'honey badger.' It inhabits S. Africa, a nearly allied species being found in India, is about 3 feet long, generally of black colour, the back being grey. The tail is short. The *R.* is very fond of honey, and is said to rob the nests of the wild bees. It is readily domesticated.

Ratchet wheel.

Rates mean taxes leviable by statutory authority on owners or occupiers of real property for local purposes. The usual mode of enforcing payment is by the authorised agent or collector applying to a justice of the peace for a distress warrant against the recusant.

Rathenau, or **Rathenow**, a town in the province of Brandenburg, Prussia, on the right bank of the Havel (here crossed by a stone bridge), 50 miles N.W. of Berlin. It is surrounded by walls pierced by six gates. It has considerable weaving, spinning, and tanning industries, as well as brickworks and manufacturing of optical instruments. Pop. (1875) 9951.

Rathkeale (Irish Gael. *Rath-Gaela*, 'Gaela's fort'), a market-town of Ireland, in the county of Limerick, on the Deel, an affluent of the Shannon, 19½ miles S.W. of Limerick by rail. In *R.* and its neighbourhood are many descendants of German Protestants, known as 'Palatinates,' settled here about the beginning of the 18th c. Pop. (1871) 2517.

Rathlin, **Island of**, an island belonging to the barony of Cary, County Antrim, Ireland. It is 6½ miles long by 1½ broad, and is 6½ miles N. of the coast at Ballycastle, its post-town. *R.* is supposed to be the island mentioned by Ptolemy as Rikina, and by Pliny as Ricinia. Its Irish name is *Rackra*, whence the form *Rachraun* and *Rachrin*, sometimes found. A religious house is said to have been founded here by St. Columba in the 6th c., and there are still remains of a fortress said to have been built by Robert the Bruce, who at one time took refuge here. In 1558 a Scottish colony, which was then inhabiting the island, was expelled from it with much slaughter by Lord Deputy Sussex. Most of the surface of *R.* is rocky pasture. The geological formation is basaltic, and takes a columnar form on the E. side similar to that of the Giant's Causeway and Fingal's Cave. Kelp-burning used to be largely carried on here, but since kelp has gone out of demand the population has fallen off from 413 (1841) to 1039 (1871).

Rat'ibor, a town of Prussian Silesia, on the left bank of the Oder (here crossed by a bridge 320 feet long), 11½ miles from the Austrian frontier, and 85 S.W. of Breslau by rail. It was almost entirely rebuilt after the fire of 1858, and has five churches, a gymnasium, and several charitable institutions. It is the seat of the Upper Silesian Court of Appeal, and was from 1288 till 1532 the capital of the principality of the same name. *R.* has manufactures of damasks and woollens, and produces brandy, tobacco, and glass. It has also an important transit trade in corn and wood. Pop. (1875) 17,269.

Ratification, in Scotch law, is the ceremonial sometimes gone through by the maker of a deed legally to establish the fact of its having been made without intimidation. *R. by a wife* is made by her declaring in presence of a judge, her husband being absent, that she has not been induced by him, by force or fear, to execute the deed.

Rating in the Navy. 1. *Rating of Men*.—The rating according to his qualifications of each sailor in the ship's books. Persons who have never previously been to sea are rated as ordinary seamen of the second class, and practised sailors as ordinary or able seamen, according to their experience. 2. *Rating of Ships*.—All large ships in the Royal Navy are registered under one of six rates, according to the number of men or the complement of guns which they carry. The following table (then under revision) shows the different rates of ships as on 1st January 1878:—

- 1st Rate. All ships carrying 110 guns, or 1000 men and upwards.
 2d Rate. One of Her Majesty's yachts, and all ships carrying between 81 and 109 guns, or between 800 and 799 men inclusive.
 3d Rate. Her Majesty's other yachts, all flag-ships and guard-ships, and all ships carrying between 60 and 80 guns, or between 600 and 799 men inclusive.
 4th Rate. All frigate-built ships carrying between 410 and 599 men inclusive.
 5th Rate. All ships carrying between 300 and 400 men.
 6th Rate. All other ships carrying a captain.

The other vessels in the navy are divided into (1) sloops, (2) gun-vessels, and (3) all other ships and smaller vessels commanded by lieutenants.

Ra'tio. See PROPORTION.

Ra'tion in army and navy, the allotment of food, fuel, &c. granted to each soldier and sailor for his daily maintenance. In the British army the peace ration includes $\frac{3}{4}$ lb. of meat, 1 lb. of bread, 37 lbs. of coals for every 12 men, $2\frac{1}{2}$ gills of oil for every 18 men, and such groceries and vegetables as the soldier chooses to buy. The war ration is 1 lb. fresh or salt meat, 24 oz. of bread or 1 lb. biscuit, 2 oz. rice, 2 oz. sugar, 1 oz. coffee or $\frac{1}{2}$ oz. tea, $\frac{1}{2}$ oz. salt, 1 gill spirits, and fresh or preserved vegetables. A stoppage of 1d. per day is made when the war ration is supplied. When a soldier's wife accompanies her husband abroad, he receives half a R. for her, and from $\frac{1}{2}$ to $\frac{1}{3}$ of a R. for each accompanying child, according to its age. In India a soldier's ration is 1 lb. meat, 1 lb. bread, 4 oz. rice, $2\frac{1}{2}$ oz. sugar, $\frac{7}{8}$ oz. tea or coffee, $\frac{3}{4}$ oz. salt, 1 lb. vegetables, and 3 lbs. firewood. The R. of forage for army horses is 10 lbs. oats, 12 lbs. hay, and 8 lbs. straw, which the men receive free, and for which the officers pay 8d. per day. The rations supplied in the navy are 1 lb. meat, $1\frac{1}{2}$ lb. ship biscuit or $1\frac{1}{2}$ lb. soft bread, $\frac{1}{2}$ pint spirits, 2 oz. sugar, 1 oz. chocolate, $\frac{1}{2}$ oz. tea, $\frac{1}{2}$ lb. vegetables, and various extras. According to scientific investigation, the nutriment for able-bodied men doing heavy work should have three carboniferous for every nitrogenous element. Soldiers in Continental armies are not generally so well fed as British troops. In the Franco-German war pea-sausage was largely supplied to the German army, and was found portable and nutritious, while it made good soup.

Ra'tionalism has been defined as 'a certain cast of thought or bias of reasoning, which leads men on all occasions to subordinate dogmatic theology to the dictates of reason and of conscience; in history, to attribute all kinds of phenomena to natural rather than miraculous causes; in theology, to esteem succeeding systems the expressions of the wants and aspirations of that religious sentiment which is planted in all men; and in ethics, to regard as duties only those which conscience reveals to be such.' The rise of this spirit in Europe is marked by the decline of the belief in magic and witchcraft which began in the 14th c. Since the Reformation on Protestantism as a basis, various modifications of R. have been built—by the Arminians, the Socinians, the Deists of the 17th c., and the more thorough-going Rationalists of the 18th c. in England, France, and Germany. In the 16th c. Christianity was regarded as a system entirely beyond the range of human reason, a system which it was impious to question or examine. It was hissing all over with miracles, which excited no scepticism and no surprise. On the other hand, the central conception of R. is that conscience has supreme authority as the religious faculty, and that religion is no exception to the general law of progress and uninterrupted development, Christianity being a conception which is to become more and more spiritualised as the human mind passes into new phases. The best-known characteristic of R., however, because it is the first direction it invariably takes, is the attempt to explain away the miracles of Scripture. See Farrar's *Critical History of Free Thought* (Bampton Lectures, 1863); Hurst's *History of R.* (New York and Lond. 1866); Lecky's *History of R. in Europe* (4th ed. Lond. 1870); and Hodge's *Syst. Theology* (Edinb. 1873).

Ra'tios, Prime and Ultimate, the name employed by Newton to denote the fundamental principles of limits as established geometrically in the opening sections of his *Principia*. The ultimate ratio of two small variable quantities is the limit to which their prime or real ratio continually approaches as they are diminished indefinitely. Thus the ultimate ratio of an arc and its sine is unity, since as both are made smaller and smaller, the

ratio approaches nearer and nearer to unity, and may be made to differ from it by less than any assignable quantity. See LIMIT.

Rat'isbon. See REGENSBURG.

Rattans', or **Rattan Canes**, are the long flexible stems of various species belonging to the genus *Calamus* (q. v.) or allied genera. The species are chiefly found in India and the Eastern Archipelago, where they grow in the forests, climbing over trees and bushes to a greater extent than any known plants. The stems vary very much in length, but 100, 300, and 500 feet are of ordinary occurrence, and Rumphius states that one kind attains the extraordinary length of 1200 feet. In the countries where these palms abound the inhabitants make use of them for a great variety of purposes; chairs, mats, door-blinds, hats, baskets, and other useful articles of plaited work being manufactured from strips of the stems, but the most important services they are utilised for is as mooring-cables for the coasting vessels, and as ropes where immense strength is necessary. From *C. montanus*—a native of the Himalaya up to 6000 feet—the light but strong suspension-bridges spanning the large rivers of Sikkim are constructed; it also supplies material for the strongest ropes for dragging logs of wood from the forests. The R. used in lieu of ropes on timber rafts in Burma are referred on good authority to *C. latifolius*, a common species in the moist valleys of that country, where its stem, 200 feet long, terminating in an elegant crown of leaves, may be seen surmounting the gigantic trees over which it climbs. *C. Rotang*, *C. rudentum*, *C. verus*, *C. viminalis*, and probably several other species, furnish the canes or R. imported in large quantity into Europe for the bottoms of chairs, couches, sides of carriages, window-screens, and other purposes. The Malacca cane of Sumatra is generally ascribed to *C. Scipionum*, which Loureiro erroneously described as from Cochin-China. The flesh surrounding the seeds in *Calamus* is a delicate article of food, and the young shoots of some species, while still tender, are roasted or boiled, chopped small, and being fried with pepper and gravy, are said to furnish a very palatable dish. See CANE and DRAGON'S BLOOD.

Ratt'any, or **Rhat'any** (*Krameria triandra*), is a pretty little shrub, a native of Chili, Peru, and Bolivia, at elevations from 3000 to 8000 feet. A preparation of the root is used as an astringent medicine; it also acts as a tonic and as a styptic; and the dried powdered root forms an ingredient of many dentifrices. An extract is said to be extensively employed to give astringency and colour to artificial port wine. Some other species of this anomalous genus have similar astringent properties, particularly *R. Jume* from Central America and the W. Indies.

Rat-Tailed Maggot, the name given to the *Eristalis tenax*, one of the flies in its larval condition. It inhabits the mud of ponds and ditches. The abdomen ends in a long breathing tube opening by two terminal 'spiracles,' and bearing hair-like appendages. There are seven pairs of 'prolegs.' The chrysalis buries itself in the earth.

Rattaz'zi, Urba'no, an Italian statesman, born at Alessandria, Piedmont, June 29, 1810, was educated at a Government school, practised as an advocate at the Turin bar, and in 1838 removed to the Court of Appeal then recently established at Casale. When Carlo Alberto proclaimed his constitution in 1845, R. was returned to the Lower Chamber of Sardinia as the ultra-Liberal representative of the College of Alessandria. After the battle of Custoza he acted as a member of the ten days' Ministry, and subsequently he filled the office of Minister of the Interior, a post he was deprived of on the change consequent on the battle of Novara and the abdication of Carlo Alberto. Thereafter he and a few friends formed what was termed the left centre, while Cavour led the right centre. By degrees the republicanism of R. was modified, and in 1854 he found himself able to accept the Minister of Justice's portfolio in the Cavour Ministry. As Minister of Justice he put forth all his powers against the Clerical party; but subjected to continual opposition, which fatigued rather than conquered him, he retired at the general election in 1857. In the following year a large majority elected him president of the Chamber, and after the peace of Villafranca he replaced Cavour, took an active part in the arrangements for the annexation of Tuscany, Bologna, Modena, and Parma, and pushed the organisation of the new Italian kingdom. In 1860 Cavour regained the power, and R. retired. He died June 5, 1873.

Rattlesnake (*Crotalus*), a genus of snakes belonging to the section *Viperina*, in which there are no teeth in the upper jaw save the poison-fangs and their rudimentary successors. It forms the type of a distinct family, that of the *Crotalidae*, in which there is a large pit or depression between the nostril and the eye. In the genus *Crotalus* itself the head has posterior scales, and the scales of the lips are large. The R. inhabits N. America. The best known species are the *C. horridus*, named popularly the banded R. or Caravel, the *C. or Uropophis durissus*, and the small or Miliary R. (*Crotalus miliaris*). The chief characteristic of these reptiles is the possession of a number of horny joints or rings on the tail, which make a rattling noise when the snake moves. The number of the 'rattles' is said to increase with the age of the animal. The exact use of this curious apparatus is still undetermined, and its analogy is by no means clearly made out. Professor Shaler, United States, thinks that the R. imitates through its movements the note of the Cicada, an American insect; and that birds swooping down to seize the supposed prey, are in turn seized by the serpent. The R. is a highly poisonous reptile, its bite proving fatal within a short period. Its average length is from 6 to 8 feet. The colour of the *C. horridus* is brown, with a black streak in the side of the neck. The *U. durissus* is of paler brown colour, and the small R. is brownish olive, and attains a length of 2 or 3 feet.

Rauch, Christian, a German sculptor, born 2d January 1777 at Arolsen in Waldeck. After studying under Ruhr at Kassel, he came to Berlin (1797) as valet of King Friedrich Wilhelm II. The king dying in the autumn of that year, R. entered the service of his successor, Friedrich Wilhelm III. and Queen Luise. In 1804 they sent him to Rome, where he enjoyed the society of Wilhelm von Humboldt, Canova, and Thorvaldsen. Among the earliest works of R. are the bas-reliefs 'Hippolytus and Phædrus,' 'Mars and Venus wounded by Diomedes,' a colossal bust of the King of Prussia, a life-size bust of Queen Luise, and several busts for the Walhalla (Regensburg). In 1811 R. returned to Berlin to execute the celebrated monument of Queen Luise, which was finished in 1814. His activity grew with his fame. His other chief works were his statues of Bulow and Scharnhorst at Berlin (1815-22), numerous busts (before 1824 he had completed as many as 70, 20 of these being of colossal size), the bronze statues of Blücher at Breslau and Berlin (1826), of Francke at Halle (1826), of King Max of Bavaria at Munich (1829), and of Dürer at Nurnberg (1838), the six colossal 'Victories' in the Walhalla (1836), and the equestrian monument of Friedrich the Great at Berlin (uncovered May 1851), which is considered his masterpiece. Equally great in noble ideal representation and in truth to nature, R. is recognised as one of the first of modern sculptors. He died 3d December 1857.

Baumer, Friedrich Ludwig Georg von, born at Wörlitz, near Dessau, May 14, 1781, proceeded from the Joachimsthal Gymnasium at Berlin to the universities of Halle and Göttingen, and after holding various legal offices was called to the chair of history in the university of Breslau (1811). His tour, made at the cost of the King of Prussia, in Germany, Switzerland, and Italy (1815-17), bore splendid fruit in a *Geschichte der Hohenstaufen und ihrer Zeit* (6 vols. 1823-25; 4th ed. 1871), where R. sought to confirm the reviving consciousness of German nationality. He became professor of political economy and history at Berlin (1819), was led by his historical researches to Paris (1830), and imperilled his favour with the court by withdrawing from the Superior College of Censors (1831). A liberal speech on Friedrich the Great's saying, 'Each of my subjects shall be happy according to his liking,' cost R. his membership of the Berlin Academy (1847), but procured his election to the Frankfurt Parliament, whence he was sent on an embassy to Paris. In 1853 he was created a member of the Upper House, but retired thenceforth from politics, though continuing to lecture down to his ninetieth birthday. He died June 14, 1873, at Berlin, which owes to him several of its people's libraries. R. was author of *Vorlesungen über die alte Geschichte* (2 vols. 1821; 3d ed. 1861), *Geschichte Europas seit dem Ende des 15. Jahrhunderts* (8 vols. 1832-50), *Beiträge zur neuern Geschichte aus dem Britischen Museum und Reichsarchive* (5 vols. 1836-39), *Handbuch zur Geschichte der Literatur* (4 vols. 1864-66), and various works of

travel, *Herbstkreise nach Venedig* (1816), *Briefe aus Paris und Frankreich* (1831), *England*, 1835 (2 vols. 1836; 2d ed. 3 vols. 1842), *Italien* (1840), *Die Vereinigten Staaten von Nordamerika* (2 vols. 1845), &c. See his *Lebenserinnerungen und Briefwechsel* (2 vols. Leips. 1861).—**Karl Georg von R.**, brother of the preceding, was born at Wörlitz, April 9, 1783, and studied at Göttingen, Halle, Freiburg, and in the Pestalozzian Institute at Iffert. He became professor of mineralogy at Breslau (1811), served on Blücher's staff through the War of Liberation (1813-14), accepted a call to Halle (1819), and to Erlangen (1827), where he died, June 2, 1865. Of his many admirable works on geology, geography, and education, may be mentioned *Geognostische Fragmente* (1811), *ABC-Buch der Krystallkunde* (1821), *Lehrbuch der Allgemeinen Geographie* (3d ed. 1848), *Beschreibung der Erdoberfläche* (6th ed. 1866), and *Geschichte der Pädagogik* (4 vols. 1842, et seq.; 4th ed. 1872-74). See his *Selbstbiographie* (Stuttg. 1866), and Scheurl, *Zum Gedächtniss K. von R.'s* (Erl. 1865).—His son, **Rudolph von R.** (born at Breslau, April 14, 1815; died at Erlangen, August 30, 1876), as professor at Erlangen of the German language and literature, published some valuable contributions to German philology, *Einwirkung des Christenthums auf die althochdeutsche Sprache* (1845), *Geschichte der Germanischen Philologie* (1870), *Erläuterungen zu den Ergebnissen der Berliner Orthographischen Konferenz* (1876), &c.

Rau'pach, Ernst Benjamin Salomo, a prolific German dramatist, was born at Straupitz in Silesia, May 21, 1784. In 1801 he entered the University of Halle, where he underwent a course of study in theology, after which he acted for ten years as a teacher in Russia, and was appointed professor of philosophy (1816) and of German literature (1817) at St. Petersburg. In 1822 he left Russia, and after travelling in Italy, settled in Berlin, where he died, March 18, 1852. R.'s dramatic works were arranged by himself in the two divisions, *Dramatische Werke erster Gattung* (18 vols. Hamb. 1830-44), and *Dramatische Werke komischer Gattung* (3 vols. Hamb. 1828-34). Of these the chief are *Die Fürsten Chawansky* (1818), *Die Gefesselten* (1821), *Der Liebe Zauberkreis* (1824), *Die Freunde* (1825), *Isidor und Olga* (1826), *Rafale* (1828), *Die Tochter der Luft* (1829). His *Lustspiele* appeared in 1828, and subsequently *Kritik und Antikritik*, *Die Schleichhändler*, *Der Zeitgeist*, *Das Sonett*, and the farces *Denk' an Casar* and *Schelle im Monde*. A collection of tales issued in 1820 and another in 1833 were less successful. He published a cycle of sixteen dramas on the history of the Hohenstaufen emperors (Hamb. 2 vols. 1837-38). The later works of R. were contained in the *Jahrbuch deutscher Bühnenspiele* of Gubitz, and were *Jacottine von Holland* (1852), *Der Kegelspieler*, *Mulier tacet in Ecclesia* (1853), and *Saat und Frucht* (1854). The plays of R. have merits which are theatrical rather than dramatic. See Pauline Raupach's R., *eine biographische Skizze* (Berl. 1854).

Ravallac, François, assassin of Henri IV., was born in Angoulême, 1578; became successively a clerk, valet-de-chambre, solicitor, and schoolmaster. While imprisoned for debt, he contracted a habit of seeing visions, which induced him, on his release, to adopt the religious life recommended to him by the Jesuits. He is remembered only for his infamous murder of Henri, May 14, 1610. In the Rue de la Ferronnerie a block occurring, R. stepped up, put his foot on the wheel of the royal carriage, and plunged a knife into the king's heart. R. escaped at the time, but was shortly captured, knife in hand, taken in charge by the Duc d'Epemon, and, after condemnation by the Parliament, torn asunder by wild horses (May 27, 1610). His crime was attributed to the Spanish Court and to Marie de Médicis. Kitchin remarks that 'it is best to believe that he had no direct accomplices, and that he instinctively did the work of the party of which he thereby became, in a sense, the representative.' He declared to the end he had no partners in the enterprise. See Kitchin's *History of France* (vol. ii.); Henri Martin, *Histoire de France*.

Ravana, in Hindu mythology the demon-king of Lanka or Ceylon, is depicted as a giant with ten faces, who carried away Sita, the wife of Rama, and whose destruction by her avenging husband with the aid of the monkey Hanuman forms the subject of the great Hindu epic, the *Ramayana* (q. v.). As the monkeys represent the negroid aboriginal tribes in the centre of the peninsula, so R. is supposed to stand for a Dravidian monarch.

Ravelin (Fr. *ravelin*, Ital. *rivellino*, from Lat. *re*, and *vallum*, 'fortification'), a triangular outwork, constructed to cover the curtain and shoulders of the bastions. It is open at the rear, and has two faces forming a salient angle, two demigorges formed by the counterscarp, and is surrounded by a ditch which separates it from the covert way. Within it a smaller work of a similar kind is sometimes erected, termed a *redoubt*, the salient angle of which is defended by a *bonnet*, the sides of which are parallel to those of the R. The ditch before the redoubt of the R. is defended chiefly by *tenailles*, and *lunettes* are works erected at its sides. See FORTIFICATION.

Raven (*Corvus corax*), a species of *Corvidæ* or Crows, very widely distributed over the surface of the globe. Its colour is a bluish black, and the female is larger than the male R. A large specimen may measure about 2 feet in length. The bill is very strong, the upper mandible overlapping the lower. The R. does not exhibit the usual gregarious habits of crows. It is bold and wary, and has been known to attack even comparatively large animals, such as rabbits and hares, and even lambs. The R. has the faculty of imitation highly developed, and may learn to utter short words. It may attain a venerable age, instances having been known of a R. having lived for sixty or seventy years. It has from time immemorial been regarded as a bird of evil omen, a result probably due to its sombre appearance and croaking notes.

Ravenna, one of the oldest cities of Italy, capital of the province of R., 43 miles S.E. of Bologna, lies in a swampy valley, between the rivers Lamone and Ronco, and is connected with the Adriatic by the Naviglio Canal. It has an art-gallery, a library containing 50,000 volumes and many valuable MSS., an archaeological museum, and fifteen churches. The most notable buildings are the cathedral of St. Orso, dating from the beginning of the 5th, and restored in the 18th c.; the adjoining *Baptistery*, a splendid specimen of Byzantine architecture; the church of *San Francesco* (founded 450); the *Tomb of Dante*, who died in R.; the church of *San Vitale* (consecrated 547), an imitation of the church of St. Sophia at Constantinople; the church of *San Apollinare Nuovo*, a basilica erected about 500 by Theodoric the Great; and, a little way outside the town, the church of *San Apollinare in Classe* (consecrated 549, restored 1779), the finest extant basilica. Near R. is the famous pine-forest, *La Pineta*, celebrated by Dante, Boccaccio, Dryden, and Byron. R. has manufactures of silk, linen, paper, and glass. Pop. including suburbs (1874) 18,414.

History.—R. was founded either by the Etruscans or by a Greek colony from Thessaly, but was of no importance until Augustus constructed the harbour (*Clarus*), and made it the headquarters of the Adriatic fleet. The deposits brought down by the river Po have not only filled up the harbour, but extended the coast-line so greatly that R. is now upwards of 5 miles from the sea. In 402 the seat of the Western empire was removed thither by Honorius. It was taken in 493 by Theodoric, and was still 552 the seat of the Ostro-Gothic kings. For the next two centuries it was the residence of the Byzantine exarchs. In 755 Pippin (q.v.) of France handed it over to the Pope. Between 1275 and 1509 it was governed by independent dukes and by the Venetians, and from 1509 to 1860 it was, with one short interruption, in the hands of the Pope. In 1512 the French, under Gaston de Foix, who was killed in the battle, defeated the Spaniards and Papal troops under the walls of R. See Spreiti, *Dell Origine e della Magnificenza della Città di R.* (2 vols. Rav. 1793-96); Quast, *Die Altchristl. Bauwerke zu R. vom 5 bis 6 Jahrh.* (Berl. 1842); Habsch, *Die Altchristl. Kirchen, &c.* (Karls. 1863); John Henry Parker's *Mosaic Pictures in Rome and R.* (1866); Pasolini's *Delle Antiche Relazioni fra Venezia e R.* (Flor. 1874); and *The Goths at R.*, in the *British Quarterly Review* for October 1872.

Ravensburg, a town of Wurtemberg, in the fertile Schussenthal, 11 miles N. of Friedrichshafen on the Bodensee by rail. It has one Protestant and two Catholic churches, a medieval rathhaus, a lyceum (1809), a realschule, and a wealthy hospital. There are cotton, woollen, hemp, and flax manufactures; paper, oil, and grain mills. Pop. (1875) 10,034.

Ravenscroft, Thomas, an English composer, was born in London about 1590. As a boy he was a chorister in St. Paul's Cathedral under Edward Pierce. He published his *Melismata*, musical phantasies fitting the court, citie, and country humours, to

3, 4, and 5 voices, in 1611, and a *Brief Discourse in defence of the old musical notation* in 1614. His arrangement of *The Whole Book of Psalms, with the Hymnes Evangelical and Songs Spirituall, composed into 4 parts by sundry authors* (1621-23), was the finest collection of psalm tunes which had appeared, and contained many beautiful melodies of his own composition. He died in London in 1635. A selection of his works was published by the Roxburghe Club in 1823.

Ravi, one of the five rivers of the Punjab, identified with the Hydrastes of the Greeks, and still called Trastee in certain parts of its course. It rises among the Himalayas, and flows S.W. past the city of Lahore, till its junction with the Chneaub: total length, about 450 miles. At Madhapore, where it debouches on the plains, a large canal system takes off to irrigate the sandy desert of the Bari Doab, which lies between the R. and Bias rivers. The total cost has been £2,000,000 sterling, and the net profit is £50,000 per annum. The main canal is 212 miles long, and there are 692 miles of distributaries. The number of acres irrigated in 1872-73 was 228,000; the rate for water varies from 12s. to 3s. per acre.

Ravignan, Gustave François Xavier Delacroix de, born at Bayonne, December 2, 1795, quitted the bar for the seminary of Saint-Sulpice in 1822, and passed thence into the Society of Jesus. After some years' employment in the work of education, he grew into fame through the discourses, grave, elegant, and closely reasoned, which he delivered at Amiens and in the churches of St. Thomas Aquinas and Notre Dame at Paris. He died February 26, 1858, and his *Conférences* and *Entrétiens Spirituels* were published in the following year. R.'s defence of his order, *De l'Existence de l'Institut des Jésuites* (1844; 7th and enlarged ed. 1855), created a deep sensation at the time of its appearance. See his *Life* by Father de Pontevey, S.J. (Eng. trans. Dubl. 1869).

Ra'wicz, or Ra'witch, a town of Prussia, province of Posen, near the borders of Silesia, 37 miles N.N.W. of Breslau by rail. It has a fine rathhaus, and a 'real-chule' of the first rank. Leather, oil, and tobacco are manufactured; and weaving, spinning, and brewing are carried on. There is also a considerable trade in corn. Pop. (1875) 11,155.

Rawlinson, Sir Henry, K.C.B., an Oriental scholar and Indian diplomatist, was born at Chadlington in Oxfordshire in 1810, and entered the Bombay army in 1826. In 1833 he was selected to assist in disciplining the Persian army, and while in that country was led to study the cuneiform inscriptions, of the interpretation of which he is one of the joint discoverers. He first deciphered the rock inscriptions of Behistun (q.v.) in 1838. During the Afghan expedition of 1839-42 he served as political or diplomatic officer with the force that occupied Kandahar; and he is now the sole survivor of this branch of the service who was connected with the fatal war. He was made agent at Bagdad in 1844, and lieutenant-colonel in Turkey in 1850; in 1850 was knighted, and appointed a director of the East India Company and elected a member of Parliament in 1858; and in 1859 he was sent as minister to the court of the Shah. Since 1868 he has been a member of the Council of India. From 1859-60 he again sat in Parliament, and from 1871 to 1875 he was president of the Royal Geographical Society. R. has received many honours both at home and abroad, and has been president of the Society of Biblical Archaeology since its foundation in 1873. He acquired wide celebrity by his translation of the Persian text of Darius, first published in the Transactions of the Royal Asiatic Society in 1846, and has since contributed to the same journal many valuable memoirs on this and other Eastern subjects. With E. Norris and George Smith, he edited 5 vols. folio of cuneiform inscriptions, 1861-70, and furnished much of the material for his brother's edition of Herodotus. In 1874 he published *England and Russia in the East*, in which he advised the occupation of Herat by the British, as a check to the advances of Russia in Central Asia.—**Rev. George R.**, brother of the preceding, born 1815, is Camden Professor of Ancient History in the University of Oxford, and Canon of Canterbury. He is best known by his translation of Herodotus in conjunction with Sir G. Wilkinson (4 vols., 1858-60), and by his elaborate *Five Great Monarchies of the Ancient Eastern World* (4 vols. 1862-67; 3d ed. 1876); *Manual of Ancient History* (1869); *Sixth Great Oriental Monarchy, or the Geography, History, and Antiquities of Parthia* (1873); *The Seventh Great Oriental Monarchy, treating*

of the Sassanians (1876). He has also written the commentaries on the book of Kings, &c., for the *Speaker's Commentary*, and contributed an essay on the Pentateuch to Thomson's *Essays and Reviews*.

Rawul Pindi, the chief town of the district and division of the same name, in the Punjab, British India, on the Grand Trunk Road, 160 miles N.W. of Lahore. Pop. (1868) 19,228, with an additional 6581 in the cantonments, which lie S. of the town. There are stationed here one regiment of hussars and two of European infantry, as well as artillery and native troops. R. has a considerable trade in country produce; and since 1860 the largest horse-fair in N.W. India has been held here, under Government patronage.—The district of R., which lies among the spurs of the Himalayas between the rivers Indus and Jhilum, has an area of 6216 sq. miles; pop. (1868) 711,256. It contains the ruins of Taxila city, visited by Alexander; Attock, where the Indus has been always crossed, and the sanitarium of Murri. The crops are wheat, millet, and barley. The camels, mules, donkeys, and horses of the district are celebrated.

Ray, the name given to several species of fishes belonging to the order *Elasmobranchii* (q. v.). In the family *Raie*, to which both skates and rays belong, the body is flat and very broad. The breadth of the body, however, is due, not so much to its own actual breadth, but to the fact that the large *pectoral* or *breast fins* are united with the body itself, and thus serve to increase its area. The tail is markedly slender. Its upper lobe is prolonged over the lower, thus causing it to appear *heterocercal*. The body is sparsely covered with *placoid scales*, and some species have large spines on the tail. Of the rays, the common R. or skate (*Raja batia*) is a well-known genus. The Thornback R. (*R. clavata*) is common round the British coasts, and derives its name from the large size of the spines on the back and tail. The tail of the sting R. (*Trygon pastinaca*) is covered with a large spine, the sides of which are toothed or serrated. The eagle R. (*Myliobatis aquila*) has also a prominent tail-spine. Its tail is exceedingly slender, and from this latter circumstance it has received the name of 'whip R.' The Homelyn R. (*R. miraletus*) has large dark spots on the sides; and the Bordered R. (*R. marginata*) a dark border on its side-fins, and three rows of tail-spines. Most famous of the R., however, is the Horned R. (*Cephaloptera*) of the Mediterranean Sea. Specimens of this latter fish, weighing over a ton, and measuring 20 feet in length and 8 in breadth, have been obtained. The Electric R. is the *Torpedo* (q. v.) of naturalists.

Ray, or Wray, John, born at Black Notley, Essex, November 29, 1628, passed from Braintree Free School to Catherine Hall, Cambridge, but migrated to Trinity, where he became a fellow (1649), Greek lecturer (1650), mathematical tutor (1652), and junior dean (1658). He accepted episcopal ordination at the Restoration, but was ejected by the 'Black Bartholomew Act' (1662), and thenceforward mainly devoted himself to natural science, having already published a *Catalogus Plantarum circa Cantabrigiam nascentium* (1660). With his friend Francis Willoughby, of Middleton Hall, Warwickshire, he travelled over Great Britain and on the Continent (1663), in 1667 was elected a Fellow of the Royal Society, and after some years' residence in Warwickshire settled in his native village (1679), where he died, January 17, 1705. One of the earliest natural systems of classification in botany was that proposed by R. in his *Methodus Plantarum* (1682; 2d ed. 1703). He distinguished flowering and flowerless plants, dividing the former into Dicotyledons and Monocotyledons. His orders were thus correctly based upon affinities, and R., whilst far outstripping his contemporaries, may be regarded as the forerunner of Jussieu, Decandolle, Brown, Endlicher, &c. Amongst R.'s numerous writings were his *Catalogus Plantarum Anglie* (1670), *Historia Plantarum* (3 vols. 1686–1704), and *Synopsis methodica Animalium Quadrupedum et Serpentinum Generis* (1693). He also edited and enlarged Willoughby's *Ornithologia* (1676) and *Historia Piscium* (1686), and published a *Collection of Unusual or Local English Words* (1674; edited by Professor Skeat for the English Dialect Society, 1874), and a *Collection of English and other Proverbs* (1678), besides various religious treatises. His *Life and Select Remains*, by Dr. Derham, appeared in 1760; and the R. Society, founded in 1844, has devoted two volumes of its *Transactions* to his *Memorials* (1844) and *Correspondence* (1848), edited by Dr. E. Laukester.

Raymond, the name of seven counts of Toulouse. **R. I.**, in 852, succeeded his brother Fredelon, who had been granted the lands of Toulouse by Charles the Bald, and added to them the county of Querci. He died in 864 or 865.—**R. II.** succeeded his father, Eudes, in 918. Next year he drove back the invading Saracens under Abd-er-Rhaman IV., and in 923 defeated the Normans. He died in 923, and was succeeded by his son, **R. III.**, who is also known as **R. Pons**. This prince defeated the Hungarians in 924, driving them beyond the Alps. He died in 950.—**R. IV.**, known as **R. de Saint-Gilles**, succeeded his brother, Guillaume IV., who was without male heirs, in 1088, uniting to the hereditary dominions of Toulouse the earldoms of Rouergue, Nîmes, and Narbonne, which he had acquired in 1066 by a marriage with the daughter of his uncle Bertrand, Comte de Provence, which procured him ten years later the excommunication of Pope Gregory VII. He married in 1080 Mathilde, daughter of Roger, Count of Sicily, and in 1094, Elvire, daughter of Alfonso, King of Leon and Castile, becoming by his alliances one of the most powerful princes in the S. of Europe. In 1096 he left his dominions for Palestine at the head of the third army of the Crusaders, and in 1100 went to Constantinople, leaving it next year at the head of 100,000 Christians; but this undisciplined army was soon routed on the plains of Cappadocia, and R. was obliged to return to Constantinople. Returning to Syria in 1102, he was seized at Tarsus by Tancred, his mortal enemy, and only recovered his freedom at the prayer of several princes, who put him at the head of an expedition against Tripoli in 1103. Here he died in 1105.—**R. V.**, grandson of the preceding, was born in 1134, and began to reign in 1148. The claims of Henry II. of England to the suzerainty of Toulouse through Eleanor his wife, daughter of Guillaume IV., were opposed by Louis VII. of France, but were satisfied by a partial submission of R. in 1193. He died in 1194, and was succeeded by his son, **R. VI.**, who was born in 1156. Under his mild rule the doctrines of the Albigenses spread widely, and his court was rendered brilliant by troubadours whom his generosity attracted. R. was obliged to promise to extirpate the 'heretics,' but being unwilling to persecute the greater number of his subjects, he was excommunicated by the papal legate, Pierre Castelnau, and this sentence was soon after ratified by the Pope. Alarmed at the threatened invasion of his territories by the neighbouring barons, R. yielded, but the assassination of the legate in 1208 laid him under the suspicion of having caused his death, and he was once more excommunicated, while an interdict was laid on his territory, and a crusade preached against him, and inculcated on all true Catholics. In 1209 an army of 100,000, under Simon de Montfort, invaded Toulouse. His submission and visit to Rome in 1210 having proved unsuccessful, R. took up arms, and at first was successful; but on September 12, 1213, he was defeated with a loss of 15,000 men, his noble ally Peter of Arragon being among the slain. R. now retired to England; but, after the Council of Lateran had ratified all the actions of Montfort, he returned to Toulouse, flung himself into his capital in 1217, and defended it for ten months, until the death of Montfort obliged the Crusaders to raise the siege. R. now recovered most of his former territory, but died suddenly in the August of 1222.—**R. VII.**, son of the preceding and last sovereign of his house, was born at Beaucaire in 1197. Amauri, the son of Montfort, having handed over his claims upon Toulouse to Louis VIII., the latter marched against R. A new crusade was preached against him, and in June 1226 Louis appeared before Avignon, which fell after three months' resistance. His death in November 1226 alone saved R., when his enemy had advanced within 12 miles of Toulouse. Notwithstanding some partial successes, he found himself obliged to submit to a rigorous and humiliating peace, April 1229, in which he bound himself to punish heretics without mercy, to pay immense fines to the Church, to raze the walls of Toulouse and thirty other towns; lastly, to give his only daughter in marriage to one of the brothers of Louis IX., and go against the Saracens in Palestine. The hatred of the people, as shown by the driving the inquisitors from Toulouse and Narbonne in 1236, was attributed to his schemes, and he was once more excommunicated, and subjected to many indignities. He died September 27, 1249, when on the point of setting out for Palestine, having the mortification to see his dominions pass under the sway of the house of Capet. See Catel, *Histoire des*

Comtes de Toulouse; and Moline de Saint-Yon, *Histoire des Comtes de Toulouse* (4 vols. Par. 1862).

Raynouard, François Juste Marie, born at Brignoles, in the modern department of Var, September 8, 1761, was educated at Aix, and after a short legal practice at Draguignan, became a deputy in the Legislative Assembly (1791). He suffered imprisonment during the Reign of Terror, carried off the Institute's prize of poetry (1803), and achieved an immense success with a national tragedy, *Les Templiers* (1805), though, like his other dramas, *Caton d'Utique* (1794) and *Les États de Blois* (1814), it lacks action, and reproduces the tone but nothing of the genius of Corneille. His poems, too, *Socrate dans le Temple d'Aglaure* (1803), *Camœns* (1819), &c., are poor and prosaic, all their author's power being avowedly reserved for the closing line, 'the crack of the whip,' as he was pleased to style it. A native of Provence, it is as an investigator of his country's speech and literature that R. is best remembered. To the works already mentioned under PROVENÇAL LANGUAGE may be added *Éléments de la Grammaire Romane* (1816), *Des Troubadours et des Cours d'Amour* (1817), and *Influence de la Langue Romane* (1835). R. was secretary to the French Academy (1817-25), of which he had been elected member in 1807, and died at Paris, October 27, 1836.

Razor (Fr. *rasoir*, from *rasér*, 'to shave' or 'scrape'), an instrument with a fine cutting edge for shaving. First-class razors are made of the best cast steel, perfectly hardened and tempered. The edge of a R. is composed of a microscopic and regular series of saw-like teeth, so that the operation of shaving resolves itself into one of mowing. Sheffield is the great seat of the R. manufacture in Great Britain, and several qualities of razors are there made. A black-handled Sheffield R. of good and well-tempered steel may be purchased for one shilling; while others of cast iron are sold at the rate of sixpence per dozen for export to S. and W. Africa and the islands of the Pacific for native use. Sharks' teeth and oyster or mussel shells are used for shaving in New Caledonia and other South Sea Islands. Captain Cook, the intrepid navigator, once resigned himself for six hours into the hands of a native royal barber, the operation being performed with a sharpened oyster-shell.

A *R-strop* is usually a leather-covered flat strip of wood. One side is smeared with R.-paste, compounded of oxide of iron, emery powder, or putty powder and hog's lard or other unctuous matter; while the other side, on which the keenness of edge is finally imparted, has either the soft leather plain or blackened with plumbago and lard.

Razor-Bill (*Alca torda*), a species of Auk (q. v.) or *Alcida* common in the Arctic Seas, and found frequently on the northern coasts of Britain. It is allied to the Great Auk (*Alca impennis*), now so rarely found. The R.-B. is caught in large numbers on the Labrador coast. It attains a length of 17 inches, and is an expert swimmer and diver. The eggs number two at most, and are deposited on the bare surfaces of rocks. Both eggs and flesh are esteemed for food.

Razor-Bill

Razor-Shell and Razor-Fish. See SOLEN.

Ré, Ile de (Lat. *Rex Insula*), an island, 18 miles long by 4 broad, on the coast of the department of Charente-Inférieure, France. It is separated from the mainland by the Pertuis de Breton, from the Ile d'Oléron by the Pertuis d'Antioch, and its four fortifications serve as a protection to the harbour of La Rochelle. The population (in 1872, 16,618) is chiefly occupied in fishing, in the cultivation of the vine, in the distillation of brandy, and in the manufacture of sea salt. Oyster-beds, capable of producing 300,000,000 oysters annually, have recently been established in the neighbourhood. The capital of the island is St. Martin (pop. (1872) 2740), fortified by Vauban, and containing an arsenal. Other towns are La Flotte and Ars. The coast is rocky, but has several good harbours and two lighthouses.

Reaction (from Lat. *re*, and *ago*, 'I act'), in politics or religion a backward tendency from reform or progress. It often arises, among those who have been but half converted to a cause, from disappointment at the smallness of apparent results, but it is the almost invariable consequence of injudicious or ill-timed change. It was a reactionary feeling which the Jesuits in the 17th c. availed themselves of to check the further spread of Protestantism, and it was this which reconciled the French to the imperialism of the first Napoleon.

Reaction is the term employed in medicine and surgery to designate the process of recovery from a state of collapse. The immediate symptoms of collapse are followed by R., and in this stage the prognosis mainly depends upon the rapidity of the recovery, and on the character of the pulse when R. is established. See SHOCK.

Reade, Charles, son of Mr. John Reade of Ipsden, the most popular squire of Oxfordshire, was born in 1814. Educated by private tutors, he entered Magdalen College, Oxford, as demy, or scholar, and in 1835 he graduated third class in classics. He then obtained a fellowship from his college, and afterwards held the Vinerian Fellowship. He also obtained the degree of D.C.L., and was called to the bar, Lincoln's Inn, 1843. The first of his books were *Christie Johnstone*, a tenderly-wrought picture of Scottish life, and *Peg Woffington*, a piece of historical realism which at once raised him high in the ranks of novelists. These appeared in 1853, and were followed by a still greater success—*It is Never too Late to Mend* (1856); *The Course of True Love*, and *White Lies* (1857); *Cream*, containing *Jack of All Trades* and *Autobiography of a Thief* (1858); *Love me Little, Love me Long* (1859); *The Eighth Commandment* (1860); *Cloister and Hearth* (1861); *Hard Cash* (1863); *Griffith Gaunt* (1866); *Foul Play* (1868); *Put Yourself in His Place* (1870); *A Terrible Temptation* (1871); *A Simpleton* (1873); *The Wandering Heir* (1875); *A Hero and Martyr* (1876); *A Woman-Hater* (1877). No novelist of the day excels R. in discriminative appreciation of character, or sense of dramatic fitness. His style, terse and epigrammatic, is to be compared for effect to that of no contemporary except Victor Hugo, whom R. rivals in egotism and eccentricity, even more than in genius. Almost all his novels are written with a serious purpose—e.g., *Hard Cash* exposes the system of private lunatic asylums, and *Never too Late to Mend* that of convict prisons. R. has worked along with Tom Taylor on several plays, the most noted of which are *The King's Rival* (1854) and *Masks and Faces* (1854). His other dramas are *Gold* (1850); *Two Loves and a Life* (1854); *Wandering Heir* (1875); *The Scuttled Ship* (1877).

Reading (Celt. *rhvd*, 'a ford'), the county town of Berkshire, stands on the Kennet, just above its junction with the Thames, 35½ miles W. of London by rail. It has three parish churches—St. Lawrence, a good Perpendicular structure (restored 1868), St. Mary's (1551; restored and enlarged 1864), and St. Giles's (restored 1872), whilst the finest of its seven district churches are the cruciform Gray Friars (rebuilt 1863), Christ Church (1862), All Saints' (1864-74), and St. John's, with a spire of 172 feet, rebuilt in 1874. Among the public edifices are the Assize Courts (1861); the new Municipal Buildings (1876), with a tower of 100 feet, containing a carillon; the Royal Berkshire Hospital (recently enlarged); and the Grammar School (founded in 1486; rebuilt 1870-71), which (1878) has 8 masters and about 150 boys. Plans were approved in April 1878 for a new town-hall, to comprise a free library, reading-rooms, museum, and schools of science and art. New drainage-works were completed in 1874, and waterworks in 1878. The ruined abbey, with its fine Norman gateway (restored 1861), is surrounded by beautiful public gardens; and there are also recreation grounds of about 22 acres, 13 of which were presented to the town in 1876 by Mr. Alderman Palmer, now (1878) M.P. for R. Two world-famous establishments at R. are the biscuit factory of Huntley & Palmer, employing 2500 workpeople and using 1000 sacks of flour weekly, and Sutton's seed emporium, which covers 5 acres, and in 1877 sent out grass-seed enough for 28,000 acres. There are also extensive ironworks, breweries, flour-mills, &c. R. sends two members to Parliament, and has three weekly newspapers, of which the *Mercury* was established in 1723. Pop. (1871) 32,324. Occupied by the Danes in 871, R. rose into importance under Henry I., owing to his foundation (1121) of a stately Benedictine abbey. Four parliaments met

at R. in the reigns of Henry VI. and Edward IV.; and in the Great Rebellion it was held alternately for King and Parliament, being taken by Essex after an eight days' siege (1643). See the Histories of R. by Coates (Lond. 1802) and Man (1816).

Reading, a city of Pennsylvania, U.S., on the E. bank of Schuylkill river, 128 miles W. of New York. The streets are well laid out and kept scrupulously clean, and excellent water is abundant. There are some very costly churches, excellent schools, two handsome opera-houses, a number of fine hotels, a court-house and public offices, and three daily and several weekly newspapers. R. has blast-furnaces, rolling-mills, foundries, wool, cotton, nail, and other manufactures, flour and saw mills, and large coal trade. A great railway riot took place here in June 1877. Pop. (1870) 33,930.

Real (Lat. *realis*, from *res*, 'a thing'), a term used in English law. Property in England is legally divided into *R.* and *personal*. *R.* property comprehends lands and houses and such other things as are permanent and immovable. Things *personal* include things movable and all other things which lack the two requisites of a *R.* estate—permanency and immobility. There is also a subordinate division of *personal* estate, or chattels, into chattels *R.* and chattels *personal*. The former are interests issuing out of or annexed to *R.* estates, such as the right of presenting to a church. The latter are such articles as household furniture, money, jewels, &c. Actions and suits in English law are also divided into *R.* and *personal* according to their object. The similar but not identical term of Scotch law is *Heritable and Movable* (q. v.). In England, a mortgage is *personal* property and goes to the personal representative; while in Scotland a security affecting heritable, that is *R.* property, is heritable and descends to the heir.

Real (Span. 'royal'), a current Spanish coin, valued at 100 to the pound sterling, or equivalent to nearly 2½d. It is divided into 100 centimes, and is equal to ⅓ of a piastre. The *R.* was first coined in Spain in 1497, and was introduced into Mexico, Peru, and other old Spanish possessions. In these New World republics the name still survives, though it is no longer retained as an official coin. In Portugal it is also used as money of account, being equivalent to 40 reis.

Realgar is a native ruby-red sulphide of arsenic occurring in Hungary, Transylvania, the Harz, and other localities, in prismatic crystals, massive or disseminated. *R.*, prepared artificially, is used as a pigment, and in making coloured fires.

Realism. See NOMINALISM.

Real Presence of Christ in the Sacrament of the Eucharist is held by the different denominations of Christians in various senses. According to the Roman Catholic doctrine of Transubstantiation (q. v.), Christ is present by the bread and wine being actually changed into his body and blood. Lutherans, in their doctrine of Consubstantiation (q. v.), hold the doctrine of the *R. P.* as firmly as the Roman Catholics, only the body and blood of Christ are with, in, and under the bread and wine. Calvin, while denying the *R. P.* in the sense in which it was maintained by Romanists and Lutherans, yet affirmed that the body and blood of Christ were *dynamically* present in the Lord's Supper (q. v.). From the glorified body of Christ in heaven there radiates an influence of which believers, in the Lord's Supper, are the recipients. The Calvinistic doctrine on this point, which was at first carried as near to Lutheranism as possible in order to avoid a schism, was afterwards modified to meet Zwinglianism, which can hardly be charged with affirming the *R. P.* in any sense; but even in the Westminster Confession a certain kind of *R. P.* is affirmed:—'The body and blood of Christ . . . (are) as really, but spiritually, present to the faith of believers in that ordinance, as the elements themselves are to their outward senses.' In the famous Bennett case, heard in the Privy Council (1871), the Archbishop of York, in delivering judgment, said that the Church of England holds and teaches 'a presence of Christ in the ordinance to the soul of the worthy recipient, but as to the mode of the presence she affirms nothing, except that the Body of Christ 'is given, taken, and eaten in the Supper only after a heavenly and spiritual manner,' and that 'the mean whereby the Body of Christ is received and eaten is faith.' See Hodge's *Syst. Theology* (Edin. 1873), Blunt's *Dict. of Doct. and Hist. Theology* (Lond. 1872).

Real Schools (Ger. *realschulen*), in Germany, are secondary schools giving a general *practical* training, and are thus distinguished from Gymnasias (q. v.), which lay the foundation of a general *philosophical and liberal* education. A. H. Francke (q. v.), at the Halle Orphanage, made the first attempt to place 'Realia' on a level with classical studies. His method was carried out by Semler in his 'Mathematical and Mechanical Real School' at Halle, between 1706 and 1740, and Semler's assistant Hecker founded at Berlin in 1747 the 'Economico-Mathematical Real School,' which was favoured by Friedrich the Great, and named by him the 'Royal Real School.' The ascendancy of Philanthropinism, with its worship of bare utility, checked the movement for a time, but in 1822 Spilleke's reconstruction of the Real School at Berlin laid a firm basis for the modern system. The subjects of instruction in *R. S.* are mathematics, the natural sciences, and modern languages. The controversy excited by the demand to enforce at least Latin on the *R. S.*, which led to the foundation of 'Real-Gymnasias,' aiming at a union of both methods, was settled in 1859, by the enforcement of Latin in *R. S.* of the first order in Prussia and Saxony. Another agitation is now going on for the opening up to boys trained at *R. S.* the special studies and professions hitherto requiring gymnasial culture. *R. S.* of the second order want the two highest classes belonging to *R. S.* of the first order, while the 'Higher Burgher Schools' are simply lesser *R. S.*, with a three years' course (from the age of 12 to 15). In 1877 there were in Prussia 84 *R. S.* of the first order (14 in Brandenburg). Austria, during the school year 1876-77, had 60 'Real-Gymnasias,' and such other institutions, with 970 teachers and 12,230 pupils. In Lombardy and Piedmont, *scuole reali* were founded in 1851, divided into two grades, which in 1859 were reconstituted as *scuole tecnici* and *istituti tecnici*. Switzerland, in 1873, had 41 *R. S.*, with 3800 pupils. In 1864 an imperial decree classed all the gymnasias of Russia as 'Classical' or 'Real-Gymnasias.' A statute of the 27th May 1872 replaced the latter with *R. S.*, from which the ancient classics are entirely excluded. In 1876 they numbered 44, with 8308 pupils. See Loth, *Die Realschul-Frage* (Leips. 1870), Kreissig, *Ueber Realismus und Realschulwesen*, Gallenkamp, *Die Reform der Höheren Lehranstalten* (Berl. 1874), and (against *R. S.*), Laas, *Gymnasium und Realschule* (Berl. 1875).

Ream, a quantity of paper containing 20 quires of 24 sheets each; that is, 480 sheets in all. A *R. perfect*, for printers' use, contains 21½ quires, or 516 sheets.

Reaping (from Old Eng. *ripan*, 'to pluck,' connected with *reipian*, 'to seize'; cf. Lat. *rapere*) is that part of harvesting operations which is concerned with the cutting down of cereal crops and grasses. In addition to simple cutting down, *R.* embraces the collateral operations of binding and stooking the grain, and generally of preparing crops for carrying from the field. Although from very remote times innumerable attempts have been made to devise and apply machinery to the operations of harvesting, down till quite recent years the implements employed in *R.* were of the most simple and primitive type, and indeed to a large extent these obtain still. That strenuous efforts should have been made to introduce improved appliances is not to be wondered at, seeing that while economy of labour is of great consequence, the security of the crops with promptitude at the proper time and under favourable conditions of weather are matters of the highest importance. The possibility of using machinery in *R.*, however, depended to a large extent on the perfection to which other agricultural operations were brought; and it was only when advanced systems of farming came to be practised that *R.*-machines were found to be practically available. The implement used from the most remote antiquity for cutting down crops was the sickle or *R.*-hook, a simple apparatus consisting of a hook-shaped knife of steel fastened in a handle, which the reaper seizes with one hand and thrusts into the ripe grain immediately above the ground, while the other hand holds the stalks against its edge till they are cut. In modern times three forms of sickle are in use, the ordinary smooth-edged, the saw-edged, and the heavy or bagging sickle. It is evident that the work of *R.* with the sickle must necessarily be slow, while the manual labour in the stooping position necessary is severe. Still a large quantity of grain is annually cut down with this little implement, large bands of reapers yearly migrating from Ireland to the harvest in the grain-growing districts of England and Scotland. A modi-

fied form of bagging-hook, or rather half hook, half scythe, both in form and action, is the Hainault scythe, which consists of a heavy knife attached to a long handle or shaft, by which the reaper is enabled to stand upright and cut down the corn by striking the knife-edge forcibly against it, the shorn grain being then collected into a sheaf by means of a hook. The various forms of scythe are in labour-saving qualities a great improvement on the sickles, and for many years on large farms the scythe supplanted the R.-hook till, in its turn, it was also thrown aside for the R. machine. In R. with the scythe the grain cut down is caught by a cradle or hoop attached to the handle and heel of the blade, carried forward, and thrown up against the line of standing corn. Three persons at least are required in R. with the scythe—the scytheman, a female lifter who gathers the corn into sheaves and makes a band for banding them, and a bandster who follows, tying up the sheaves and stooking them.

The number of R. machines which have been proposed at various periods is beyond all computation; but some indication of the activity of invention may be gathered from the fact that down to the year 1866 not less than 1000 patents were sought in Great Britain alone for R. machines or for various details connected with them. It would be a mere waste of space to attempt to give any account of the various systems put forward, not one of which was successful, even experimentally, till the Rev. Patrick Bell, in the year 1826, invented his apparatus. The essential mowing principle in Bell's reaper was the cutting of the straw by means of shears, and in all subsequent machines that principle has been adopted, although its mechanical details have been much improved. The original model machine made by Mr. Bell himself is now preserved in the Museum of Science and Art, Edinburgh, and from that model it will be seen that the inventor's first idea was simply fitting a series of reciprocating scissors or cutters on a broad frame. Subsequently the cutters were so modified that the upper blades, thirteen in number, were immovably fixed to the cross bar, under which played twelve movable blades, the whole so geared that when the machine was put in motion they formed a continuous series of open jaws, opening on the one side when closing on the other, so that the cutting was effected against both sides of the upper blades alternately. An endless web of cloth having a transverse motion, and mounted angularly behind the cutters, caught the cut grain and delivered it at the off side. The first modifications of Bell's machine which received much attention were Hussey's and M'Cormack's reapers, both of American origin, and indeed since the machines were first introduced, American inventors and manufacturers have done very much for their development and improvement. In consequence of that activity, reapers of American manufacture are in extensive use in Great Britain, the European Continent, and, indeed, throughout the world.

The general features of all R. machines as now made are the same, individual manufacturers modifying only the method of mounting delivering gear and other details. The usual construction consists of a drawing wheel fixed to one side of the machine, to which is attached a spur wheel working into a series of small toothed wheels, which increase the slow speed of the periphery of the wheel to the fast motion necessary for driving the cutting knives. The knives differ somewhat in shape, but generally consist of a series of triangular pieces of steel riveted to a bar of iron, in some instances serrated on the edges. The knife bar is attached to a crank by means of a connecting-rod, and this crank, which makes about 700 revolutions in a minute, receives its accelerated motion through a train of wheels in direct communication with the large driving-wheel. The knife bar moves backwards and forwards on guides fixed at the back of a number of pointed fingers, which enter the corn crop and guide the straw to the edges of the cutting knife. A platform is fixed at the back of the cutter-bar which receives the corn as it falls from the knives. In most cases a revolving rake with four inclined arms is attached to such machines, and set in motion by the main driving wheel. Two of the arms act as gatherers for bringing the corn well on to the knife, and the others as rakes for delivering the cut corn at the back of the machine.

The most recent notable addition to the R. machine consists of an apparatus for binding the sheaves, several forms of which have been suggested. That, however, devised by Mr. W. A. Wood of New York has been practically the most successful, and there can be no doubt that the binding apparatus will soon be looked on as an essential feature in any reaper. In Mr.

Wood's reaper and binder there is an endless apron which receives the grain as it is cut and deposits it in a trough on the

Wood's Self-Binding Harvester.

outer side of the machine. In this trough by an ingenious and effective mechanical arrangement the loose straw is caught and compressed between two iron arms, wire from a reel is passed round the compressed sheaf, the wire is fastened by twisting, cut away, and the bound sheaf is then tossed out of the trough by one of the arms with which it was compressed.

Reason (Lat. *ratio*, from *reor*, 'I think') is a word used to signify (1) all the intellectual powers, taken together; (2) those intellectual powers which differentiate man from the brute, (3) the faculty of reasoning, (4) the premiss or premisses of an argument, (5) a cause—as when we say that electrical disturbance of the atmosphere is the reason of thunder. The distinction between men and brutes as rational or irrational is now being abandoned. Coleridge refines upon it by saying that in the lower creatures 'there may be understanding, but there is nothing of R,' his *R.* being that of Kant, which deals with the supersensible world of ideas, while his *understanding* deals with the sensible world and conceptions. This pure R. holds the same relation to understanding that perception holds to sensation. By the understanding we inquire into grounds, causes, conditions of phenomena; but by the R. we inquire into the *ultimate* grounds, causes, or conditions of these phenomena. See **DEDUCTION**, **INDUCTION**, **SYLLOGISM**, &c.

Réaumur, René Antoine Ferchault de, a French physicist and zoologist, was born February 28, 1683, at La-Rochelle. He went to Paris, in 1703, soon attracted attention by three geometrical memoirs, and became in 1708 a member of the Academy of Sciences. He had a special genius for inventing practical methods, and turned his attention to a number of different projects, such as the manufacture of steel, the tinning of iron, the manufacture of porcelain, &c. He is best known as the inventor of the spirit-of-wine thermometer, and of the thermometer scale which is still popular in Germany (see **THERMOMETER**). He died at his estate of Bermondière in Maine, October 17, 1757. His most important work is the *Mémoires pour servir à l'Histoire des Insectes* (6 vols. 1734-42).

Rebate, or **Rabbet**, in carpentry, a rectangular groove cut longitudinally along the edge of a piece of wood to receive the edge of another piece or pieces. The recess in a door frame into which the door shuts is a familiar example of a R.

Re'bec, or **Re'beck**, an old three-stringed instrument like a fiddle, which was in this country the precursor of the viol.

'While the merry bells ring round,
And the jocund rebecks sound.'—Milton's *L'Allegro*.

Rebell'ion (in law). The difficulty which law has to contend with regarding R. is this, that when part of the subjects of a state take arms against the authorities in power, whether the fact is to be regarded as R. depends on the force of the insurgents, or on the issue of the struggle. If the contending powers are each strong enough to carry on a protracted war, policy and humanity will lead each to award belligerent rights to the other; to award quarter to those who surrender, and to spare the lives of captives. Yet, the war being finished,

the victors may regard the vanquished as rebels. Thus, in the recent conflict in the United States, the North awarded belligerent rights to the South, yet the Northern doctrine, though it has been mercifully applied, continues to be that the Southern states were rebels. Wheaton in his *Elements of International Law* suggests the following principles:—(1) The courts of a state must treat rebels as criminals. (2) The fact that the state has treated rebel prisoners as prisoners of war, and has claimed as regards neutrals the privileges of a state of war, does not affect the first rule. (3) A foreigner holding a rebel commission takes his chance of being treated as a rebel, or as a belligerent. (4) A foreigner carrying on naval war under a rebel commission, takes his chance of being treated as a pirate, or as a belligerent, by his own nation, and by all others. (5) That though the parent state have awarded belligerent rights to insurgents, yet that their doing so concerns internal state policy only, and that the mode of action may be changed at any time. Of course the rebels will not award any rights to their opponents, or to those assisting them, or to neutrals, which opponents and neutrals do not award to them; and if the rebels succeed, then they have just such privileges of success as the parent state would have had had it succeeded.

Rebus, a species of pictorial hieroglyphics, said to be named after the squibs on passing events ('*de rebus quæ geruntur*') composed by the clergy of Picardy for the yearly carnival. In the Middle Ages many knights and ecclesiastics employed as cognisances rebuses punning on their names; thus the Lyharts bore a stag couchant, the Derings a deer and ring, and so on. At present the R. serves chiefly for padding in our lighter magazines, and the following may stand as a good representative of its kind: On the letters S T a gorgeous cockatoo sits perched, whilst beneath is a wretched moulting bird, the solution being: On S T (honesty) is the best Poll I see (policy).

Récamier, Jeanne Françoise Julie Adelaïde Bernard, one of France's most distinguished society queens, was born at Lyon, December 4th, 1777. Her father, a banker at Lyon, in 1784 removed to Paris, where he filled an important position in the Post-Office, and where his wife succeeded in drawing around her a large and fashionable circle of friends. Among these the dazzling beauty of Mademoiselle Bernard raised general admiration, and while yet a child she received, through her parents, several offers of marriage. Left entirely to her own choice, in her fifteenth year she married M. Récamier, a rich banker, nearly four times her age. Under the fatherly protection of this husband, she quickly assumed the leading position in society which her beauty and her manners were so calculated to obtain; and wisely making friends of her feminine rivals, such as Madame de Stael, whom she entirely eclipsed in the affections of all except the blind, she threw her net of fascination over men so skilfully that few escaped. Of the number of scholars and men of the world who remained through life her firm friends, nearly all commenced their intimacy with her as lovers. But she never allowed their devotion to compromise either themselves or herself. The Duc de Laval's quotation wittily describes her influence on these admirers:—

'Ils ne mouraient pas tous, mais tous étaient frappés.'

Prudent in everything except politics, Madame R. seemed formed for an object, not so much of intense passion, as of general esteem. Her capability of loving was perhaps small, but her capability of pleasing was infinite. Sainte-Beuve declares that if coquetry was hers, it was the coquetry of an angel. Adrien and Matthieu de Montmorency, Bernadotte (afterwards king of Sweden), General Moreau, Benjamin Constant, and J. J. Ampère were her most faithful adorers. But the only suitor whom she favoured in her youth was Prince August of Prussia, nephew of Friedrich the Great, and a royal prisoner in France. Madame de Stael introduced him to her friend, who agreed to marry him, and asked her husband for a divorce. Her husband had by this time lost nearly all his wealth. The assent he gave to her request touched her with commiseration for his misfortune; and she never fulfilled her strange engagement with the brave, handsome prince. In 1811 she was exiled from Paris by Napoleon; and she did not return till the Restoration. The only man besides the Prince on whom she seems to have bestowed real affection was Chateaubriand. Him, too, Madame de Stael introduced to her, but on her deathbed. When Madame R. had retired in comparative

poverty to the Abbaye-aux-Bois, she carried her society with her. Chateaubriand transferred all the attentions he had bestowed on De Stael to her beautiful friend; and for the last twenty years of her life she lavished her undivided solicitude on this hypochondriac. It was a strange ending for both. Chateaubriand became a widower in 1846, and wished to marry her. She, too, was widowed, but she preferred to remain his friend. He died July 4, 1848, and Madame R. died May 11, 1849. Gerard painted a portrait of her in her girlhood; Canova (whom she met at Rome in 1813) executed a bust of her; and Achille Devena made an exquisite sketch of her on the day of her death. See *Souvenirs et Correspondance tirés des Papiers de Mme. R.* (2 vols. Par. 1859); and *Mme. R., les Amis de sa Jeunesse et sa Correspondance intime* (Levy, Par. 1873), understood to be edited by Mme. R.'s niece.

Receipt is a legal acknowledgment of money received in discharge of a debt or obligation. In English law a R. is not necessarily a written document; it may be constituted by the evidence of witnesses who can swear to the payment of the money. In Scotland such evidence is not admissible, if the debt itself is created by writing. When the written R. is for more than £2, a penny R.-stamp is necessary to the validity of the discharge.

Receiving Stolen Goods, knowing them to be stolen, makes the offender Accessory (q. v.) to the theft. The crime may be a misdemeanour or a felony, rendering the criminal liable to imprisonment or to penal servitude of not fewer than three, or more than fourteen years. The police in London have in certain cases power to enter premises in search of stolen goods. Anyone who prints or publishes an advertisement for the return of stolen goods, *without questions being asked*, or to that effect, is liable to be fined £50. But no action can be begun without the consent of the Attorney- or Solicitor-General. The corresponding term of Scotch law is *Reset of Theft* (q. v.).

Recent, in geology, is a general term applied to deposits later than the glacial age, and is therefore equivalent to what is ordinarily known as the Human Period. See **PLEISTOCENE**, which includes all formations later than the Pliocene (q. v.).

Receptacle, or **Torus**, in botany, is the extremity of the peduncle (above the calyx), upon which the corolla, stamens, and ovary are inserted. It is sometimes little more than a mere point or minute hemisphere, but is often also more or less elongated, thickened, or otherwise enlarged. R. is also applied, in a capitate inflorescence (q. v.), to the short, flat, convex, or conical axis on which the flowers are seated.

Receptaculites, a curious fossil organism of doubtful nature. It is referred by most authorities to the *Spongida* or Sponges, but some maintain its affinities with the Foraminifera, or the corals. The fossil remains of R. occur in Lower and Upper Silurian strata. They are of cylindrical, ovoid, and discoid shape. The bodies are hollow, and have an aperture on their upper surface. Below, a thickened portion seems to indicate the original *nucleus* or beginning of the organism, the walls of which exhibit an outer and inner layer, with a spicula layer between. The inner layer is pierced by numerous apertures.

Reception of a novice is a ceremony, consisting of laying aside the ordinary dress, being invested by a bishop or priest with the novice's habit, which has first been blessed, and of having the hair cut off. This ceremony takes place after the individual has passed a few months as a Postulant (one desirous of being taken into an order), but is not to be confounded with the final R. into the order, which takes place at the end of the Novitiate, or period of probation, and which is called 'profession.' See **NOVICE**.

Reciprocal. In algebra, two quantities are said to be reciprocals of each other when their product is unity. Thus, the R. of a is $\frac{1}{a}$, and of $10, \frac{1}{10}$. In modern geometry, the theory of R. polars leads directly from a given proposition to another which is known as its R. See **POLL** and **POLARS**.

Recitative is musical declamation. Something of the kind was common in the Greek theatre. Modern R. grew probably from the aria-parlante in which poems were recited, and was

introduced into opera at the beginning of the 17th c. by Jacopo Peri. For a long time the harpsichord, subsequently the violoncello, was used to accompany R., but in modern music the whole string band usually plays soft four-part chords throughout. *Recitativo Secco* is simple R. when unaccompanied or only supported by plain chords. *Recitativo Obligato* has pronounced an elaborate accompaniment. When the R. approaches the *aria* in melody, it is called *recitativo Arioso*.

Reclaim', in Scotch law, means to appeal from the judgment of the Lord Ordinary to the Inner House. The initiatory act of the appeal is termed a *reclaiming note*. See COURT OF SESSION.

Recluse'. See EREMITES, ASCETICISM, ANCHORITE.

Recognisance is an obligation with one or more sureties entered into before a court of record, or magistrate, to do, or to refrain from doing, some specific act. In default, the R. is forfeited to the crown, and the principal and his sureties may be sued for the sums to which they are respectively bound. Justices of the peace may enforce R. at their own instance, or they may grant it at the instance of another.

Recoil' (from Fr. *reculer*, 'to fall back'), in gunnery, is the backward motion of a cannon at the instant of firing, caused by the reaction of the projective force of the explosion. The momentum with which the projectile leaves the cannon is equal to the momentum with which the cannon recoils. The much greater mass of the cannon, and the resistances to its motion which arise from friction and its weight, render its velocity much smaller than the velocity with which the projectile travels. The peculiar action of the Moncrieff gun-carriage depends upon the R., which forces the gun backwards and *downwards*, so that it may be reloaded with greater security for the gunners.

Recoll'ets (Fr., from Lat. *recollectus*, 'gathered together') is a name which seems to have been given to reformed bodies of various monastic orders in the 16th c., and especially to the Reformed Franciscans, who received this name in France, that of *Reformati* in Italy, and that of *Discalceati* ('bare-footed') in Spain, and were established as a separate association by Pope Clement VII. in 1532.

Reconnaissance, an examination of a place with a view of facilitating military or naval operations. Reconnaissances are of two kinds, (1) Offensive, and (2) Topographical or defensive. (1.) Offensive reconnaissances may be carried on either secretly or openly. In the former case the reconnoitering party usually consists of a small mounted body of men, commanded by an officer, who advance as near to the enemy's position as possible. Open offensive reconnaissances are conducted by a general officer at the head of a considerable mass of troops, and are sometimes called 'armed reconnaissances' or 'reconnaissances in force.' They are experimental movements made in order that the strength of the enemy at a particular place may be ascertained, or for strategical purposes. When it is desired to discover if a town or village is occupied by the enemy, it is usual to send a body of horsemen at full gallop through the principal street. (2.) Topographical or defensive reconnaissances are undertaken by staff officers for the purpose of obtaining information relative to the country. The qualifications required are of a high order. A reconnoitering officer should be able to judge distances correctly, to make a good rapid sketch, carefully noting the hills, woods, roads, the direction and depth of streams, bridges, canals, towns, villages, isolated buildings, and all the main features of the country, and to write a clear and accurate description, detailing its resources and capacities for maintenance of horses and troops, and the comparative healthiness and suitableness for occupation and defence of the various positions. A knowledge of the language of the country is very desirable. Reconnaissances should be made by naval and military officers before the disembarkation of troops as to the anchorage, depth of water, nature of the beach, and other salient points. Classes of instruction in reconnoitering have been established at the various military stations in connection with the Intelligence Department of the War Office. Mr. Archibald Forbes, the distinguished war correspondent of the *Daily News*, has suggested that instead of the men being drawn from various services, a special reconnaissance corps should be formed in the British army.

Rec'ord, in law, denotes the written averments and pleas of parties in a litigation, forming the basis of the future argument and decision of the cause. The higher courts of England file the records of a suit, hence they are called courts of R. They alone have authority to fine or imprison for *Contempt of Court* (q. v.) under CONTEMPT. Trial by R. means that one of the parties to a suit or action pleads in his favour the R. of a former case. Should the other party deny the plea, then the R. relied on must be produced.

Reorde, Robert, M.D., a physician and mathematician, was born at Tenby, Pembrokeshire, about the beginning of the 16th c. He studied at Oxford, and was elected a Fellow of All Souls' College in 1531. In 1545 he took his doctor's degree at Cambridge, and shortly after went to London, where he died in the debtors' prison in 1558. His chief works are *The Urinal of Physike* (1548), *The Ground of Artes*; *teaching the Worke and Practice of Arithmetike* (1549), *The Pathway to Knowledge, containing the First Principles of Geometrie* (1551), *The Castle of Knowledge* (1551), in which he compares the Ptolemaic and Copernican systems, to the benefit of the latter, and *The Whetstone of Witte, which is the Second Part of Arithmetike, containing the Extraction of Roots* (1557), a mathematical treatise which establishes his reputation as the foremost mathematician, after Vieta, of his time.

Recor'der, an old instrument of the flageolet kind.

Recorder is in England a legal officer associated with the magistrates of a city or town corporate. He must be a barrister of not fewer than five years' standing. The duties of the R. are to try prisoners who have been committed for trial by Justices of the Peace. See QUARTER SESSIONS, COURT OF.

Records, Public. A record is defined by Lord Coke as 'an authentic and uncontrollable testimony in writing, contained in rolls of parchment, and preserved in courts of record.' By Act 1 and 2 Vict. c. 94, under the title Public Records are embraced all rolls, records, writs, books, proceedings, bills, warrants, accounts, papers, and documents whatsoever of a public nature belonging to Her Majesty. And by a comprehensive definition given by the Record Commission of 1836 the P. R. are said to constitute four great classes—(1) independent documents, such as *Domesday Book* or the *Valor Ecclesiasticus* of Henry VIII.; (2) a series of enrolments, as the *Clove, Patent, and Charter Rolls*; (3) records which contain entries of judicial proceedings; (4) separate documents, such as letters, inquisitions, commissions, &c.

The R. were for the most part written on parchment, and till the time of George II. in the Latin language, except during the period of the Commonwealth, when English was substituted. The Parliament R. were mostly written in Norman-French. The custom of recording documents on rolls of parchment dates from a period subsequent to the Conquest.

Custody and Preservation of P. R.—In early times the R. of the courts, being part of the king's treasures, were preserved in his palace, but when the courts of law became stationary, the R., instead of being carried by the king from place to place, were deposited in their respective courts. The quantity of these R. increasing rapidly, further accommodation had to be obtained. Thus we find mention of the New Temple, the wardrobe of the Tower of London, the four Treasuries, afterwards consolidated into the Chapter House, and the Rolls Chapel, as repositories. The Tower, Rolls Chapel, and Chapter House, continued for many years the chief though not the only repositories, more accommodation being required. In the time of Edward I. a keeper of the rolls in the Tower was appointed, and frequent orders were issued by his immediate successors for the better care and preservation of the P. R. There were legislative enactments for the same object in the reigns of Queen Elizabeth, Charles II., and William III. But the most minute and full inquiry into the state of the P. R. was that made by the Committee of the House of Commons in 1800, and their report is the most exhaustive and comprehensive that has yet appeared. Upon that report the Commons presented an address to Geo. III. 'to give directions for the better preservation, arrangement, and more convenient use of the P. R. of the kingdom, and that they, the Commons, would cheerfully provide whatever extraordinary expenses might be incurred. During

the next thirty years several other commissions were appointed. In the year 1836 a Select Committee was appointed to inquire into the affairs of the Record Commission, and as a result of their report the P. R. Act 1 and 2 Vict. c. 94 was passed, which placed the records in the custody of the Master of the Rolls, and eventually led to the establishment of the present Record Office.

The Record Office.—This office, built in 1856, stands on the Rolls estate between Chancery Lane and Fetter Lane. It now contains the R. formerly kept in the Tower, Chapter House, Rolls Chapel, and other places. In number, antiquity, and great historical value, these R. form a collection unsurpassed by that of any other country, and they are now so well arranged that any difficulty regarding their inspection has been removed. Chief among the documents is the *Domesday Book* (q. v.) of William the Conqueror. The *Court of Chancery R.* form an unbroken series from the time of King John, and the *Exchequer Rolls* date from the days of Henry II.; the *Close Rolls*, so called from being closed or sealed up, commencing with King John, and continuing to the present time, are documents of great importance to the historian, antiquarian, and for purposes of legal reference; the *Patent Rolls*, so called from being unsealed, also from the time of King John, illustrate almost every subject connected with the history and government of the country; the *Parliamentary Rolls*, from Edward I. to Henry VIII., give the transactions that took place during each Parliament; the *Great Roll of the Exchequer*, or *Pipe Roll*, contains the yearly accounts of the Crown revenues, the rent of lands, &c.; the collection of *Fines* are R. of the transfer of lands, &c., from Henry II. to 1833, when this kind of conveyance was abolished; the *State Papers* contain the Privy Council, Secretaries of State, foreign and other correspondence, and papers on domestic and ecclesiastical affairs. These, together with the *Charter*, *Coronation*, *Memoranda* and *Originalia Rolls*, the *Rotuli Hundredorum*, *Extenta Maneri*, *Testa de Nevill*, and the *Valor Ecclesiasticus*, a survey by Henry VIII. of the abbey, monasteries, bishoprics, &c., in the kingdom, are some of the most important documents in the English national archives.

Scotland.—Prior to the return of David II. from captivity, the P. R. of Scotland are very fragmentary and incomplete. The earlier R. seem to have been wholly carried away by Edward I. None of these are now known to exist in Scotland. At the Reformation many valuable documents, preserved by the monks in the religious houses, were destroyed. In 1650, when Edinburgh Castle surrendered to Cromwell, the P. R. were removed to Stirling; but in the following year Stirling Castle, with 'all the R. of Scotland,' fell into the hands of the English, and by order of Cromwell were transported to the Tower of London. The legal documents were returned sometime between 1653 and 1657. The remaining R. which were of a historical and public character were ordered to be returned after the Restoration, but the vessel in which they were being conveyed to Scotland was wrecked, and though some of the documents were recovered, a great many valuable R. perished. Prior to 1787 the R. of Scotland were kept in a room under the Parliament-House, known as the Laigh Parliament House. On the completion of the General Register House in 1787, all the R. were removed thither. They are in the custody of the Lord Clerk Registrar.

The R. of Scotland include the Parliamentary and Privy Council Acts, the R. of the various courts of justice, Great Seal, Privy Seal and Signet R., the *Retours* of Services, dating from 1547, and the important and useful Registers of Sasines, of Inhibitions, and of Adjudications.

Ireland.—Ireland possesses no continuous series of R. Many valuable documents were destroyed during the wars which occurred in the island; others perished through the decay of age, the negligence of officials, and by fire; and many were carried off by successive governors on the expiry of their term of office; some of these are now found in the P. R. Office in England; others in the British Museum, Bodleian Library, &c. In 1810 a Commission was appointed for the care and preservation of the R. Its labours terminated in 1830. In 1867 the P. R. (Ireland) Act was passed, and a P. R. Office has been erected in Dublin.

Publication of the R.—In 1855 the Master of the Rolls received authority to prepare and print calendars and indexes to the R., state papers, and other documents in his charge, and already a large number of volumes of calendars, divided into

different series, have been published, and others are in preparation. In 1857 a plan for the publication of the ancient chronicles and memorials of the United Kingdom in a uniform series was submitted by the Master of the Rolls to Her Majesty's Treasury and adopted, and since that time about 70 vols. have been published, embracing the period from the earliest time of British history to the end of Henry VII. The publication of this series still continues. Among the more important of the early record publications may be mentioned *Domesday Book*, first published in 1783, and again in facsimile by photolithography in 1863; *Calendarium Inquisitionum post mortem* (4 vols.); *Statutes of the Realm* (11 vols.); the *Valor Ecclesiasticus* (6 vols.); *Rymer's Fœdera* (1st ed. 20 vols.); *Proceedings and Ordinances of the Privy Council of England* (7 vols.). Issued under the direction of the Lord Clerk Register of Scotland may be mentioned the *Acts of the Parliaments of Scotland* (12 vols.); *Registrum Magist. Sigilli regum Scotorum*; and the *Retours* (5 vols.); and recently *Historical Documents, Scotland* (2 vols. 1870); *National MSS. of Scotland* (1867-72); *Lord High Treasurer's Accounts* (vol. i. 1877); *Register of the Privy Council of Scotland* (2 vols. 1877-78); *Exchequer Rolls of Scotland* (vol. i. 1878). Others are in preparation.

See *Record Reports*, 1800 and 1836; *Annual Reports of the Deputy Keepers*; Cooper, *Account of the P. R.* (2 vols. 1832); Thomas, *Handbook to the P. R.* (1853); and Ewald, *Our P. R.* (1873).

It may be interesting and useful to glance briefly at some of the more valuable collections of foreign nations.

France.—The French archives accompanied the kings from place to place down to 1194, when their loss at the battle of Fréteval led to the establishment of the Trésor des Chartes in the Sainte-Chapelle of Paris. Louis XIV.'s ministers first classified the more important documents, and Louvois founded the Dépôt de la Guerre in 1668, Torcy the archives of state papers relating to foreign affairs in 1710, while in 1716 the R. of the royal household were deposited in the Louvre. Napoleon laid almost every royal collection of Europe under contribution for the aggrandisement of the Dépôt des Archives, but his spoils were mostly restored on the fall of the empire to their respective governments. The present Archives Nationales, in the Hôtel Soubise, were organised by Camus in 1790, and in 1858 comprised 300,000 charters, deeds, and other documents, divided into the four sections of history, the secretariat, the legislature, and the judicature. The Bibliothèque de la Ville possesses a considerable series of historical and political R., bequeathed by Thouret; and the departments also have each their special archives, in which are preserved many valuable documents of suppressed institutions and the former provinces. See H. Bordier, *Les Archives de France* (1855); *Musée des Archives Nationales* (1872); and *Collection des Inventaires sommaires des Archives départementales communales et hospitalières* (1862 et seq.).

Spain.—The Royal Library at Madrid includes among its 100,000 volumes the secret correspondence of Gondomar, ambassador to the court of James I., and also autograph letters from English lords, ladies, and gentry who were in receipt of Spanish pay. These have furnished Mr. S. R. Gardiner with much of the fresh materials for his *History of England from 1603 to 1616* and *Prince Charles and the Spanish Match*. Of even greater value, as shedding light on the marriage and divorce of Catharine of Aragon and on the struggle in the Netherlands are the Simancas Archives, a portion of which are now preserved in Paris, and which have in turn been utilised by Prescott, Froude, and Motley. Three volumes of a *Calendar of Letters, Despatches, and State Papers relating to the Negotiations between England and Spain, preserved in the Archives of Simancas and elsewhere*, have been edited for the Record Office—the two first, covering the period 1485-1525, by G. A. Bergenroth (1862-68); the third, in two parts, comprising the years 1525-29, by Don Pascual de Gayangos (1873-77).

Italy.—The Archivio Centrale di Friari at Venice comprises some 14,000,000 documents, the earliest dating from 883. They form 8,664,709 stitched quires, are divided in 1890 departments, and fill 298 rooms. Of this unrivalled collection Ranke, in the introduction to his *History of England*, says: 'A rich harvest of independent reports has been supplied me by the archives of the ancient Republic of Venice. The *Relazioni*, which the ambassadors of that republic were wont to draw up on their return home, invaluable though they are in reference to persons and the state of affairs in general, are not, however, sufficient to

supply a detailed and consecutive account of events. But the Venetian archives possess also a long series of continuous reports, which place us, as it were, in the very midst of the courts, the capitals, and the daily course of public business. For the 16th c. they are only preserved in a very fragmentary state as regards England; for the 17th they lie before us, with gaps no doubt here and there, yet in matchless completeness.' Six volumes of a *Calendar of State Papers in the Archives of Venice and other Libraries of Northern Italy*, extending over the period 1202-1556, have been edited for the Record Office by Mr. Rawdon Brown (1864-77). The late Sir T. D. Hardy, in his *Report upon the Documents in the Archives and Public Libraries of Venice* (1865), confines himself to the three collections of the Frari, the Marcian Library, and the Correr Museum, and calls especial attention to documents in the first relating to Catharine's divorce and to Cardinal Pole. The archives of the Vatican, first mentioned under Damasus I., are arranged somewhat chaotically in eleven rooms, and comprise a vast number of important documents, especially of the middle ages—registers of the papal acts, letters of the Popes from Innocent III. to Sixtus V. in 2016 volumes, and correspondence with nuncios and foreign nations. They offer an immense field for future research, having been only partially explored by Ranke, Raumer, Reumont, and in 1876 by Mr. Stevenson. Also at Rome, in the Church of S. Maria in Campo Marzo, are established the new Government Archives, which include the charters and documents of ex-papal authorities, suppressed monasteries, &c. The Archivio di Stato at Pisa possesses 15,994 parchment charters (one granted by Friedrich Barbarossa in 1162, another by Richard Cœur-de-Lion in 1192); the Central Archives of Tuscany—140,000 documents, arranged by Bonaini—are stored in the Biblioteca Nazionale at Florence; at Milan, the Palazzo del Censo ed Archivio contains part of the Government archives, chiefly relating to the history of the city; and the University of Bologna has a large number of ancient documents on papyrus, the *Codex Diplomaticus Bononiensis* amongst the number. At Naples the monastery of S. Severino has been since 1818 the depository of the archives of the kingdom, which include some 40,000 parchment MSS. (the oldest in Greek) dating from 703. The documents of the Angevin period number 380,000, and fill 378 volumes; and lastly, the Monte Casino Archives, rich in materials for the history of Naples, Apulia, and Calabria, occupy three apartments, and comprise 40,000 deeds and records of various kinds, charters, papal bulls, &c., dating from the 8th c. downwards.

Germany.—The archives of the towns rarely extend beyond the 12th, or of the great princely houses beyond the 13th c. The former German Empire stored its R. in four different localities—Frankfurt, Weizlar, Regensburg, and Vienna, but only those of the last-named city have been partially utilised by Don Gayangos for the Simancas Calendar. At Königsberg are preserved the archives of the Teutonic Order, those of the Hanseatic League at Lubeck, of the Swabian towns at Ulm, and of the Rhenish towns at Speier. See Seizinger, *Grundzüge der Bibliothekswissenschaft* (Dres. 1863).

Switzerland.—The public library of Berne has 3200 MSS., many of which relate to the affairs of Switzerland generally and the Canton of Berne in particular; while the 1200 MSS. contained in the cantonal library at Aarau are of great value for both French and Swiss history.

Holland.—The historical documents in the Royal Library of the Hague are very numerous, and furnish rich materials for the history of France as well as of the Low Countries. Motley calls especial attention to a series of pamphlets known as the 'Duncan Collection,' the source from which he drew that great variety of details which gives colour and interest to his narrative.

Belgium.—The Archives Générales du Royaume form the second of the collections of Brussels, uniting the character of a library of MSS. and of a state-paper office. The documents numbered, in 1838, 130,394, extending from the 12th to the 19th c., and classified in 57 divisions. They are of high historical importance, and have been well arranged by M. Gachard. See his *Notice sur le Dépôt des Archives du Royaume de Belgique* (Bruss. 1831).

The P. R. Office of Norway is in the Storting edifice, Christiania. It contains a large collection of documents, consisting chiefly of State papers from the 16th to the 19th c. The *Diplomatic Collection*, which is arranged in a separate compart-

ment, comprises about 8000 documents and letters, 2000 of which are inscribed on parchment. This supplied materials for the important work, *Diplomatarium Norvegicum: Oldbreve til Kundskab om Norges indre og ydre Forholde, Sprog, Slægter, Sæder, Lovgivning og Reitergang i Middelalderen*, collected by Lange, Unger, and Huitfeldt, and published (1849 et seq.) at the public expense. The most valuable of the papers belonging to the period 1520-37 were originally at Munich, but on the application of the Norwegian government were restored to Norway in 1829. See Raine, *Historical Papers from Northern Registers* (Lond. 1873).

United States.—Sir Archibald Alison, in stating the half-truth that Americans will have to write their own history from foreign archives, is wrong in ascribing this to the 'utter disregard' in America 'of historical records and monuments.' Large collections of important documents are gradual and natural growths, and any neglect of political records of which the early colonists were guilty has been amply atoned by the zeal of their descendants. The various states have passed laws similar to that of Massachusetts (1826) enacting that 'all books and MSS. belonging to the Commonwealth, and now in any department of the State House, be collected, arranged, and deposited' in a State Library, and that a sum be annually appropriated for the purchase of 'books, MSS., and charts,' specially relating to the Commonwealth or the United States. These State libraries, maintained at the public charge, are intended primarily for the use of the legislatures and public officials, but are virtually accessible to all persons. As illustrative of their character, it may be stated that the library of Massachusetts contains the records of the General State Court from 1629 to 1777, which reflects the entire legislative and much of the religious history of the period; while that of New York has an important series of charters, commissions, letters-patent, &c., extending from Charles II.'s grant to the Duke of York, 1664, down to the period of the Independence. The first library of Congress, founded at Washington in 1800, was totally destroyed by the British army, 24th August, 1814. The valuable collection of Mr. Jefferson bearing on the history and political affairs of America was purchased in 1815, and forms the nucleus of the present Congress Library. A collected series of the *Annals of Congress* has been published, since 1859, in an edition of 2000 copies. Of all current Congressional papers 500 copies are reserved to be bound, at the end of each session, into sets for the public libraries, historical societies, and colleges of the union.

Destruction of R.—By the law of the United Kingdom any one fraudulently taking away any record or legal writing relating to matter, civil or criminal, pending in court, is liable to penal servitude, under 24 and 25 Vict. c. 96. By the same Act, fraudulently to cancel or destroy a will may render the offender liable to penal servitude for life.

Recoveries and Fines. See FINE.

Recruiting (from Fr. *recruter*). The United Kingdom is divided for R. purposes into districts, under the charge of officers assisted by non-commissioned officers. The acceptance of a shilling or of any current coin of the realm from a R.-sergeant, with the knowledge that it is enlisting money, constitutes enlistment; but a recruit has within from 24 to 96 hours after his verbal agreement with the sergeant to appear before a magistrate, who attests his desire to enter the army, and swears him into the service. If the recruit then desires to cancel his engagement, he may do so on paying a fine of 20s. smart money, for the trouble he has caused, half of which goes to the enlisting sergeant. Recruits enlisted at the headquarters of an infantry regiment are enlisted for the subdistrict brigade to which the regiment belongs, and cannot be transferred to any other brigade without their own consent. If they are enlisted in a subdistrict they may be passed into the subdistrict brigade, or a brigade of any other R. subdistrict, or any other corps for which R. is open. Recruits may also enlist for general service, in which case they may be posted to any regiment of that arm of the service in which they enlist. Certain limits of ages, height, and chest measurement are fixed from time to time for recruits in the infantry, cavalry, and other branches of the service. Recruits may be enlisted for long or short service, the duration of these at present being 12 and 8 years respectively in the cavalry, artillery, and engineers, and 12 and 6 years in the infantry. Short-service soldiers have to serve the difference between the period of long and short service in the

army reserve. The number of recruits annually required under present arrangements in the British army in time of peace is from 30,000 to 40,000 men.

Rectifying is a process which consists simply in submitting any substance to a second distillation either to increase its strength or to free it from deleterious impurities. The complex forms of distillatory apparatus now in use in the distillation of alcohol, in many cases entirely obviate the necessity for any R. operation.

Rector, in the Church of England, is a parish priest who, unlike a vicar, enjoys the whole of his ecclesiastical dues. The title is also borne by certain heads of colleges, schools, and hospitals, by the superior of a Jesuit seminary, and by a cleric appointed by the Pope to attend to the patrimony of the Church in different states.

Rectum, the terminal part at once of the *large intestine* and of the whole alimentary tract. In some animals (*e.g.*, certain Fishes, Reptiles, Amphibians, and Birds) the R. ends in a *cloaca* or chamber common to the alimentary, urinary, and generative systems. Even in the lowest mammalia (*e.g.*, *Ornithorhynchus*) (q. v.) the R. opens into a *cloaca*; but in all other quadrupeds it terminates in a distinct *anus* or *vent*. In *man* the R. attains a length of from 6 to 8 inches. It extends from the left *sacro-iliac symphysis* (or juncture of the sacrum (q. v.) with the ilium on the left side), and passes obliquely from left to right along the curve of the sacrum, inclining slightly backwards at its termination in the anus. Contrary to the etymology of the word, the R. is not straight in its course. It does not present a sacculated appearance like the *colon*, and dilates somewhat just above the anus.

Diseases of the R.—The rectum may be the seat of various affections requiring medicinal treatment or surgical interference. Those of most common occurrence are *Hæmorrhoids* or *Piles* (q. v.), *Prolapsus Ani* (q. v.), and *Fistula* (q. v.) in *Ano*; but there are other diseases of very frequent occurrence, the more important of which are the following:—

(1.) **Fissure, or Ulcer of the Anus**, is a little crack on the edge of the bowel, hardly implicating the whole thickness of the skin, and situated in the great majority of cases towards the coccyx. It is the seat of great pain, especially when the bowels act, and the obstacle to the healing of the ulcer is in the connection of the ulcerated skin with the sphincter ani. It is more common in women than men. The treatment consists in cleanliness, attention to the state of the bowels, and the application of some such stimulant as stick-caustic. The most satisfactory mode, however, consists in exposing the whole extent of the ulcer with a speculum, and then making an incision through its whole length and depth with a straight probe-pointed bistoury. If this fails, the division of the entire sphincter may be necessary.

(2.) **Pruritus Ani, or Itching of the Anus**, is often a troublesome affection, and in some cases may almost oblige the sufferer to renounce society. It is usually symptomatic of some digestive disorder, and may be cured by careful attention to the state of the bowels and the regulation of the diet. The local treatment consists of astringent and sedative lotions with scrupulous cleanliness.

(3.) **Polypos of the R.** is most common during childhood. Two forms are described, the vascular and the fibrous, but the difference is rather of degree than of kind. These polypi are often attached by long stalks to the bowel, so that when they float up into the gut they are imperceptible and cause no symptoms; but when they are carried down they are grasped by the sphincter, and this gives rise to pain and bleeding. The polypos may be detected by making the bowels act by an enema, when it will probably be seen as a small, red projection at the anus, or it may be felt and drawn down by passing the finger round the bowel. The removal of polypos is best effected by tying the base and cutting it off close to the ligature.

(4.) **Mucous Tubercles and Condylomata** are chiefly syphilitic affections, though they may proceed from the irritations of gonorrhœal and possibly other discharges. Mucous tubercles are small, perfectly flat, sessile elevations covered with a velvety or warty and moist epidermis. Condylomata are large, pedunculated projections covered with a foul warty surface, and exhaling a foetid moisture. They are frequently very vascular, and may bleed to an alarming extent when removed.

(5.) **Stricture of the R.** may be simple or cancerous; but

both are accompanied by the same symptoms of mechanical obstruction in proportion to their extent. The more prominent symptoms are constipation followed by diarrhœa, distension of the abdomen, and indigestion, loss of appetite, health, and complexion, depending upon the setting up of inflammation and catarrhal discharge in the mucous lining of the bowel from retention of the feces. *Simple stricture* depends on the deposit of fibroid material in some portion of the bowel which may be due to chronic inflammation, or the healing of ulcers, more especially those of a strumous nature, which may result in the formation of firm bands of cicatrix, narrowing the calibre of the intestine. In *cancerous stricture*, the morbid deposit is infiltrated into the walls of the bowel and the neighbouring tissue, producing a hard, irregular, nodular mass, extending for some distance from the seat of obstruction. There are in addition the general symptoms of the cancerous cachexia.

Treatment.—When the stricture is *simple*, and when the cause on which it depended has passed away, dilation may be successfully accomplished either gradually, by means of bougies, or rapidly by incision; but the latter mode should be practised only in cases in which the method of gradual dilation fails, or is too painful owing to the density of the cicatricial tissues, and even in such cases dilation by the bougie must be afterwards practised. The operation may be performed by means of an ordinary hernia knife, but the bistouri-caché is a safer instrument. *Malignant or cancerous* stricture can be treated by palliative measures only, as every form of mechanical treatment merely aggravates the disease. Relief may be afforded, for a time, by opening the bowel above the seat of stricture, but this is admissible only in urgent cases. Cancer of the rectum may be either epithelial or scirrhus, and it may remain for a long time without spreading to the neighbouring viscera.

Malformations of the R. may consist in imperforate anus, in which case there is no anal opening; or in imperforate R., in which case the anal opening does not lead into the bowel. In many cases the obstruction is formed by a mere membrane, but usually the lower end of the gut is at no great distance, and the malformation may be remedied by operation.

Redan (Fr., in the 17th c. *reden*, or *redent*, 'a toothed-work'), or **Flèche** (Fr. 'arrow'), in fortification, the simplest form of field-work, consisting of two faces forming a salient angle towards the enemy, and thus resembling the *tooth* of a saw.

Red Admiral Butterfly (*Vanessa Atalanta*), a well-known species of Butterflies, of a glossy black colour above, the front wings being marked with a band of red which passes across the wings to their hinder margin. The hinder wings have a red border, and the under parts are yellowish. The R. A. B. occurs in England, Scotland, on the Continent, and in N. America. It is found in Britain late in autumn, but disappears in October. The larvæ feed on nettles, and are dark green in colour, the sides being marked with a yellowish band.

Redbreast (*Erythacus rubecola*), a species of *Insectorial* birds belonging to the sub-order *Dentirostres*. The R. is one of the most familiar birds in Britain, and is recognised by the colour of the breast of the male, the hue in the female being less marked. The bill is short and tapering, and slightly notched at the top. The R. remains in Britain throughout the year. It is common on the Continent, and also occurs in N. Africa. In winter especially the R. becomes bold and familiar, and ventures within dwellings for the purpose of obtaining food. It is pugnacious in disposition; its song is sweet, but neither strong nor varied in its register. The nest is built of soft moss, feathers, and hair, and the eggs, numbering five or six, are white, spotted with brown. The R. is fond of worms, insects, and berries.

Red Colours. Red pigments, or painters' colours, are numerous, and are derived from various sources, some being obtained from the mineral kingdom in a native condition, and others formed by artificial means. The most important and valuable red pigment is vermilion, a sulphide of mercury, which occurs native as Cinnabar (q. v.), but for painters' use it is principally elaborated by artificial means. Biniodide of mercury is another valuable red colour, giving a very rich, strong, scarlet shade. Antimony vermilion is a comparatively new pigment, possessing some of the qualities of true vermilion. It consists of an oxysulphide of antimony, and is artificially prepared. Chrome red is a third red colour, having a vermilion-like hue.

It is a basic chromate of lead, and is sometimes called Austrian vermillion. Minium, or red-lead, is an oxide of lead in very extensive use. Among other red pigments may be enumerated Venetian and Persian red (the peroxide of iron), the red ochres, suboxide of copper, red oxide of tin, and purple of Cassius. There are also numerous red lakes, of which the chief are carmine and madder lake. Red dyes are more numerous and important than any other range of colours. They include cochineal and its allies, in the animal kingdom; the lichen dyes, madder, and allied substances; the red woods, and an endless variety of the artificial derivatives of aniline, phenol, and other products of gas-tar. Nearly all the substances mentioned will be found noticed under their own proper heads.

Red Crag. See **PLIOCENE**.

Red Coral (*Corallium rubrum*), a well-known species of *Sclerobasic Corals*, found in the Mediterranean Sea, and valued on account of the red hue and for the lustre it is capable of showing after being highly polished. As in all other sclerobasic corals, the R. C. has the living parts external to the coral, the latter forming a hard central axis. In the living bark the coral-polype has the coral imbedded. Each polype has the eight fringed tentacles characteristic of the order *Alcyonaria*, or that including the familiar 'Dead-Man's-Finger' polype (*Alcyonaria digitatum*) of the British coasts. The R. C. is of slow growth, and strict laws have been framed for the regulation of the fishery. The animal nature of the R. C. was discovered by Jean André de Peyssonnel, a French naturalist, whose discovery was rejected by the French Academy of Sciences, but afterwards fully confirmed by independent research.

Red Deer. See **STAG**.

Redditch, a town of Worcestershire, 13 miles S.W. of Birmingham by rail, has two modern churches, St. Stephen's and St. George's (1876). It is a great seat of the needle trade, and also manufactures pins, fish-hooks, and fishing-tackle. Pop. (1871) 6737.

Reddle, or **Red Chalk**, a soft clay iron ore, imported from Hessa, Thuringia, Silesia, and other parts of Germany as a material for making crayons. It is a light brownish red mineral; and coarser varieties are obtained from the Mendip Hills in Somersetshire, from Wastewater in Cumberland, and also from several places in Devonshire. The R. of Rotheham, Yorkshire, is the best material known for polishing spectacle glasses.

Redemption, in theology, means the salvation of sinners by Christ. Literally it means the liberation of a slave or a captive by the payment of a ransom. In the New Testament, Christ is represented as giving his own life as a ransom for sinners. The triple yoke from which men need to be liberated is the power of sin, the law, and the guilt of sins committed. It is specially from the last that St. Paul speaks of the R. of Christ delivering men. His theory is briefly as follows: (1) Christ dies. (2) The believer unites himself to Christ by faith so essentially that Christ's death becomes actually his own death ('if one died for all, then all died'—not 'were dead' (2 Cor. v. 14, 15), the 'old man is crucified' with Christ (Rom. vi. 6). (3) But he that is dead is freed from sin (Rom. vi. 7), so that he who thus dies with Christ is justified by his faith; he may truly be reckoned as one dead in respect of his past sins, provided that he is henceforth 'alive unto God' (Rom. vi. 11; cf. Gal. ii. 20). The various theories regarding the R. of Christ which have been evolved in theology are connected with the various views regarding the nature of the Atonement (q. v.). See Hodge's *Syst. Theology* (Edin. 1873); Reuss's *Histoire de la Theol. Chrétienne* (3d ed. Strasb. 1864).

Redemptionists were an order of monks founded 1198 by two Frenchmen, Jean de Matha and Felix de Valois, the principal object of which was to procure the redemption of Christians who were captives among the infidels. To this purpose a third part of their revenues was devoted. The society was consecrated to the Trinity, and hence received the other name of Trinitarians.

Redemptorists. See **LIGUORI**.

Red-Eye, or **Rudd** (*Leuciscus erythrophthalmus*), a Teleostean freshwater fish belonging to the *Cyprinidae* or Carp family.

It resembles the roach, and has a short but deep body, of a general red colour, the iris of the eye being of a bright red hue. A large R. will attain a weight of over 2 lbs.

Redgrave, Richard, R.A., the son of a manufacturer, was born at Pimlico, 30th April 1804, and received his earliest art instruction as a designer in his father's factory. He became a student at the Royal Academy in 1826, and his first success as a painter was a picture exhibited at the British Institution, 'Gulliver on the Farmer's Table,' bought for the purpose of engraving. He acquired a high reputation for his genre painting, happy specimens of which are 'The Wedding Morning' (1844) and 'Country Cousins' (1848); and was subsequently even more successful in landscape subjects, such as 'The Woodland Mirror' (1852) and 'Old English Homestead' (1854). During the latter years of the Government School of Design he was headmaster, and subsequently Inspector-General of Art-Schools, an office which he resigned in 1875, after about thirty years' service, receiving a pension of £750 a year. Subsequently, together with Mr. Cole he formed the Museum of Ornamental Art at Marlborough House, now the Museum of Art at South Kensington. Since 1858 he has been surveyor of Crown pictures, and has prepared a catalogue of such works. He is also favourably known as the author of *An Elementary Manual of Colours* (1863) and *A Century of Painters of the English School* (1866), the latter in conjunction with his brother, **Samuel R.**, who died 20th March 1876, and whose valuable *Descriptive Catalogue of the Historical Collection of Water-Colour Paintings in the South Kensington Museum*, with a preface on the history of this branch of art, appeared in 1877.

Red Gum, or **Strophulus**, is a disease of infancy, characterised by an eruption of small pimples, usually situated close together on the most exposed parts, as the face, arms, and hands. When the pimples are red it is called *S. confertus*; when large and white, *S. candidus*; and when intermixed with red spots, *S. intermixtus*. The eruption is generally accompanied by slight itching, and occasionally by considerable pain from irritation and cracking of the skin. R. G. usually occurs in infants during their first dentition, and is almost always an acute disease, seldom lasting longer than a month. The eruption is generally due to disorder of the bowels or irritation about the gums, and in most cases it will subside in a few days by attention to the state of the gums and of the digestion.

Red Hand, in heraldry, a sinister hand, erect, open, and couped. It is the arms of Ulster and the distinguishing badge of baronets.

Red-Hot Shot, cast-iron projectiles heated to redness, and used in warfare for incendiary purposes. A miniature in a 15th c. MS. in the Ambras collection at Vienna testifies to their employment at that time. The most memorable instance of their successful use was at the siege of Gibraltar in 1779-83.

Re'ding, Aloys von, a Swiss patriot, was born in the canton of Schwyz in 1755. He at first entered the Spanish service, and left it with the rank of colonel in 1788, when he became captain of the militia of his native canton. In this capacity he drove back the invading French at Morgarten, May 2, 1798, and, after the establishment of the Helvetic republic, strenuously advocated the restoration of the old federal constitution. The dissatisfaction of his countrymen with the Helvetic constitution obliged R. to convene a diet at Schwyz, which occupied itself with framing a new constitution. All his attempts to gain the consent of Napoleon, however, proved unsuccessful, and his reforms only led to the disarmament of the Swiss by the French troops. R. was arrested by order of General Ney, and confined for some months in the fortress of Arburg. In 1803 he was chosen *landamman* of Schwyz, and in 1809 he bore the same title at the diet of Friburg. In 1813 he conducted the negotiations for the neutrality of Switzerland, but showed his hatred to the French by opening the passage of the Rhine and communication through the Swiss territory to the allied forces. R. died in the town of Schwyz, February 5, 1818. He was a man of pure patriotism, but he lacked the decision of character necessary for a great political rôle.

Red Lead. See **LEAD**.

Red Liquor is the name under which one of the most important mordants used in calico printing is known. It is an ace-

tate of alumina, and owes its name to the fact that the dye colours it produces with madder, alizarine, and logwood are red and pink. The R. L. is prepared by treating a concentrated solution of sulphate of alumina (alum cake) with acetate of lead, whereby a sulphate of lead is formed and precipitated, leaving the acetate of alumina in solution.

Redoubt, or **Redout** (Fr. *redoute*, Ital. *ridotto*), in fortification, a small enclosed work of various form—polygonal, square, triangular, or even circular. A square R. is usually without bastions, or any means of flank defence. A triangular R., if without bastions at the corners, has, instead of them, complete bastions in the middle of its sides. As redoubts cannot defend their own ditches, and are easily approached at their salient angles, they are used mainly as temporary field-works. A R. of masonry enclosed within another work, as a last retreat for the garrison, is sometimes called a *Reduit*.

Redowak, a Bohemian dance in triple time, somewhat resembling a polka.

Red'pole. See LINNET.

Red' River, so called from the colour of its sedimentary matter, the last important affluent of the Mississippi, rises in the great Stake Plain in the Pan-Handle of Texas, on the E. border of New Mexico, flows E. between Texas and Indian territory, for the first 100 miles through a very steep cañon, from 5 to 20 miles wide, and 200 to 1000 feet high, S.E. through Louisiana, and joins the Mississippi 341 miles from its mouth, after a tortuous course of 1550 miles, 1246 of which are navigable in high water. Eighteen of its affluents are navigable, the chief being the Washita, Negro, Big and Little Wichita, &c.

Red River of the North, rising in Elbow Lake, Western Minnesota, U.S., 1680 feet above the sea, flows S. and then W. as far as Breckenridge, 953 feet above the sea, the head of the steam navigation. Thence flowing N., it separates Minnesota and Dakota, and at an elevation of 792 feet crosses into the British possessions, where it traverses Manitoba, and falls into Lake Winnipeg, after a course of 750 miles, and a total fall of 1072 feet. The chief affluents are the Cheyenne, Pembina, and Assiniboine.

Red' River, or **Selkirk Settlement**, a colony of British America, called also Pembina and Assiniboia, which was founded by the Earl of Selkirk in 1811, along the course of the Red River of the North. It has been (since 1871) included in the province of Manitoba (q. v.) as a part of the Dominion of Canada.

Red-Root is the popular name for several American plants, but is more particularly applied to *Ceanothus Americanus*, a small shrub belonging to the natural order *Rhamnaceæ*, with downy leaves and stems, and numerous small white flowers. The plant is used for dyeing purposes, and also as an astringent. An infusion of the dried leaves occasionally serves as a substitute for tea, hence the other name of the plant, 'New Jersey tea.' Other species of the genus furnish ornamental hardy and half-hardy shrubs for the garden, and several Californian species are recommended for hedges, in consequence of being evergreen, and their branches becoming densely intricate.

Redruth, a town of Cornwall, situated on the brow of a hill 414 feet high, on the highroad from Penzance to Truro, and 10 miles W.S.W. of the latter by rail. It consists mainly of one long street, has a church dedicated to St. Uny (rebuilt 1768), and publishes a weekly newspaper. The tin-mines of the district employed 2395 men in 1871, the copper-mines 635, and there are also iron foundries. Pop. (1871) 10,685.

Red Sea, or **Arabian Gulf**, the N.W. arm of the Indian Ocean, connected with the Arabian Sea by the Straits of Babel-Mandeb, and divided from the Mediterranean by the Isthmus of Suez. It separates Arabia from Africa, and has a general N.W. direction from the straits in the S. at 12° 39' N. lat. and 44° E. long., to the N. end of the Gulf of Suez 39° N. lat. and 33° E. long. Its length is 1380 miles, and its breadth varies from 18 miles at the entrance to 220 at 16° N. lat., after which it maintains an average of 100 miles until the division at Râs Mohammed into the two arms separated by the Peninsula of

Sinai, the Gulf of Akabah (Bahr-el'-Akabah), and the Gulf of Suez (Bahr-es-Suweis). The latter, the R. S. of the Hebrews, has a length of 180 miles and an average breadth of 20 miles, while the former is 100 miles long and 15 miles in average breadth. The bed of the R. S. consists of a long valley, both sides of which are made up of coral reefs that form two chains of islands and rocks stretching along the shore and dividing the sea into 3 parallel channels, of which the middle one is the broadest and deepest. The average depth of the R. S. in the middle is from 420 to 640 feet; the greatest depth hitherto ascertained is 1124 feet, 115 miles N.W. of Jeddah. The abundance of these reefs, and the sudden and violent winds which are frequent, render navigation very difficult. From May to October, the prevailing wind is the N.W. monsoon; for the rest of the year, the S.E.; but in the N. part, from Suez to Jeddah, N. winds blow throughout the greater part of the year. It was formerly believed that there was a difference in the levels of the R. S. and the Mediterranean, variously stated at from 30 feet to 3 feet 3 inches, but it is now known that the levels are really the same. The R. S. receives no rivers except torrents at irregular intervals, and its pure pellucid water has an intensely blue colour which appears greenish over the coral reefs. Its temperature is very high, in the middle between 14° and 24° N. lat.; in the winter months it is seldom lower than 79° F., in March and April 84° F., in May occasionally as high as 90° F., while 106° F. has been experienced in September. The chief islands from N. to S. are Jubal, St. John's, Kamaran, and Perim, besides the groups of Farsan (q. v.) and Dhalac (q. v.). The principal ports on the African side are Suez, Cosseir, Suakin, and Massowah, and on the Arabian side, Yembo, Jeddah, Loheieh, and Mocha.

The origin of the name R. S., which is a translation of the Latin *Rubrum Mare* and the Greek *Erythra Thalassa*, is uncertain. The Hebrews called it *Yam Sâph* ('weedy sea'), and the Arabs still give it the name of *Bahr Souf*, which has the same meaning. The R. S. is first mentioned in the Hebrew Scriptures as having been passed by the Israelites under the guidance of Moses, and Solomon is said also to have had ships at Elath and Ezion Geber on the Gulf of Akabah. Under the successors of Alexander it became the chief means of commercial communication between Europe and India. It was navigated by the Arabs in the 9th c., and between the 12th and 15th centuries the Venetians carried on a great commerce on its waters, until the discovery of the passage round the Cape of Good Hope opened up another route. Since the establishment of the Overland Route to India, and still more since the opening of the Suez Canal, it has recovered its importance as one of the principal channels for the commerce of the world, and the chief means of communication between the E. and W.

Red'shank. See SANDPIPER.

Red'shid, or **Résch'id Pasha**, a Turkish statesman and reformer, was born of a wealthy family at Constantinople in 1802. He first became familiarised with political affairs as secretary to Ali Pasha, governor of the Morea, and afterwards as a protégé of Pertew Pasha, Minister of Foreign Affairs, by whom he was sent to assist in the negotiations with Russia at Adrianople in 1829. He also had an important hand in the treaty of Kutahia in 1833. He spent two years (1834-36) in diplomatic residence alternately at Paris and London, where his urbane manners secured for him the friendship of the leading western statesmen. Recalled to high office in Turkey, he initiated a liberal policy, and put in practice the lessons he had learned in constitutional Europe. But intrigues such as have stopped so many efforts at improvement in Turkey procured his dismissal, and he was again engaged in diplomacy, till on the death of the Sultan Mahmud he became the chief minister of Abdul Medjid. After the battle of Nezib he concluded the Quadruple Alliance which secured the Porte from the ambitious designs of Mehemet Ali. In 1839 he proclaimed the Hattishef of Gulhane, a new charter of civil and religious government, which he endeavoured with indifferent success under his various administrations to carry out. R. was ambassador at London in 1841, Grand Vizier 1846-52, and he was also in power during the war with Russia. He died January 7, 1858. R. was one of the most able, liberal, and unprejudiced of Ottoman statesmen. He was an admirer of English institutions, and his foreign policy was always partial to this nation. He

negotiated two commercial treaties with England and France which were of great service to his country.

Red Snow is 'the common name of *Protococcus nivalis*, which in an incredibly short space of time produces large patches of brilliant scarlet on the surface of snow in the Arctic regions or amongst the Alps.' Although Aristotle appears to refer to R.-S. in *Hist. Anim.* v. cap. 19, it was not until Saussure called attention to his discovery of it on St. Bernard, in 1760 (*De Saussure, Voy.* ii. p. 646), that the phenomenon and its origin attracted notice in the world of science. The report and specimens brought home by Captain (afterwards Sir James) Ross from his Arctic expedition in 1819 increased the general interest in the subject; and the chemist, the botanist, and the zoologist in turn examined the extraordinary substance; the most prominent investigators being Peschier, Wollaston, R. Brown, F. Bauer, Baron Wrangel, Agardh, R. K. Greville, Carmichael, Hooker, Kunze, Unger, Martius, Shuttleworth, Agassiz, Meyen. Whilst some considered the organism to belong to the animal kingdom, others pronounced it to be a fungus, and others, again, a lichen. Agardh placed it amongst the *Alge* in his *Systema Algarum*, and Sir W. J. Hooker described it in the 'Appendix to Parry's second Voyage' as *Palmellia nivalis*.

Redstart (*Ruticilla phænicea*), an *Insectorial* bird belonging to the *Dentirostral* group, and allied to the Robins (*Erythrinae*). The tail, from the jerking movements of which the name is derived, is of a red colour. The common R. is tolerably plentiful in Britain in summer. The head, back, and wings are grey; the forehead is white; there is a black patch at the base of the bill; the throat and neck are black; and the wings brown. The under parts are pale brown. The eggs number five or six, and are of a greenish blue. The R. feeds chiefly on insects. An American bird, *Setophaga ruticilla*, belonging to the family *Muscicapidae*, or that of the Flycatchers (q. v.), also receives this name.

Reduction, in arithmetic, is the changing of quantities from one denomination to another. Thus multiplying by 12 reduces shillings to pence and feet to inches; dividing by 20 reduces shillings to pounds sterling, and hundredweights to quarters avoirdupois.

Reduction, in Scotch law, means the proofs of law by which the legal effect of a deed is annulled. The requisite action can only be at the instance of one having an interest in the matter.

Reduction, in metallurgy, is one of the chemical processes by which metals are freed from the impurities contained in the various ores. Sulphur, arsenic, or other volatile substance, is simply removed by *roasting* the ore in a reverberatory furnace, but when oxygen is present R. is carried out. This process consists in heating intensely the ore in contact with a reagent, such as carbon, which takes up the oxygen and *reduces* the ore to a metallic state.

Redwing (*Turdus iliacus*), a species of thrush (*Turdinae*)

Redwing.

found in Britain in winter, and inhabiting northern regions in summer. It attains the size of the common thrush. Its colour is a warm brown on the upper plumage, and a greyish-white below. The R. derives its name from the presence of a large spot of red on each side of the body; this patch being brought to view when the wings are spread in flight. The eggs number four or five, and are of a bluish tint spotted with black.

Red Woods comprehend a class of woods very extensively used in dyeing and calico-printing. There are two classes of R. W.; one, in which the tinctorial substance is readily soluble in water, comprehends Brazil-wood, Pernambuco-wood, Nicaragua-wood, and Sappan-wood, &c., all great trees of the leguminous genus, *Cæsalpinia*. The second class, embracing woods

which do not yield up their dye to water, and cannot in consequence be used as extracts, includes Sandal-wood, *Pterocarpus santalinus*, barwood and camwood, species of *Baphia*, also all leguminous trees. These woods are more resinous in their nature than the *Cæsalpinia*, and yield more enduring colours.

Ree, Lough, a lake in Ireland, formed by an expansion of the Shannon. It is 17 miles long, and separates Roscommon (Connaught) on the W. from Longford and Westmeath (Leinster) on the E.

Reed is the name given to an appurtenance of the Loom (q. v.). It consists of a series of parallel flat wires (formerly slips of cane or *reed* were used) called 'dents,' held at proper distances apart by two parallel wooden rods placed at their extremities. It is set in the swinging frame called the *lathe*, and the warp threads are separated by being passed through the spaces between the 'dents.'

Reed (Old Eng. *hreed*, Ger. *riet*; the root is doubtful) is the popular name for the largest of the British grasses, known botanically as *Phragmites communis*. It is a common plant by the sides of rivers, lakes, pools, &c., luxuriating in alluvial and tenacious clayey soils, and by its extensively creeping root-stalks soon forms dense marginal barriers. The plant grows to the height of 6 to 10 feet, and when its very large, soft, dull-purple, nodding panicle is in perfection, the masses of the R. produce a striking scenic effect in the landscape. It has a wide distribution, occurring in the four continents and in Australia. From the coarseness of the herbage, cattle in general refuse it, although they eat it if cut into chaff prior to flowering, and mixed with other food; and it contains a considerable proportion of nutritious matter. In some parts the hay is found very convenient for littering cattle, and the dried stems are used largely for thatching purposes. In the allied genus *Arundo* is included the largest of the European *Gramineæ*, namely, the evergreen *A. Donax*, supposed to be the R. of the New Testament. Its canes or stems are sufficiently tall and strong to form fishing-rods, and were formerly used as arrow-shafts (see *Iliad*, xi. &c.). They also furnish material for musical-instrument makers. This plant has been introduced into gardens for ornamental effect, for intercepting the view of unsightly objects, and for giving early shelter. From the split stems of the tall R. named *A. Karka* the Durma mats are made.

Reed in music is a thin strip of wood or metal used in certain instruments, such as the oboe, fagotto, and clarinet, the pulsations of which cause a number of rapid vibrations of air. One R. is free, the other lying over or within an aperture, and actuated by forcibly directing through this aperture a current of air. The rapidity of vibration and pitch depends on the length and weight of the R. and its relative thickness at the two ends. If thick at the free end and thin at the fixed, the tone is grave; or if the reverse, acute. There are two kinds of reeds, the beating and the free. The former, used in the clarinet, is larger than the aperture which its pulsations alternately close and open. The latter, used in the harmonium, is slightly smaller than the aperture, and its pulsations moving within the current alternately allow and interrupt the passage of air. The tone of reeds is intensified by the addition of a pipe or tube. The manufacture of R. organs is carried on in America to a great extent.

Reed, Edward James, C.B., M.P., naval constructor, was born at Sheerness, September 20, 1820, and educated at the School of Mathematics and Naval Construction, Portsmouth. He gained practical experience in shipbuilding in Sheerness Dockyard, after which he edited the *Mechanic's Magazine*, and became secretary to the Institute of Naval Architects. In 1859 he drew attention to the room for economy of time and cost in the building of ironclads, and he was appointed Chief Constructor of the Navy in 1863. His views regarding turret ships not meeting with acceptance, he resigned this appointment in July 1870. He was returned to Parliament for Pembroke as a Liberal in February 1874, and has since been consulted by the Admiralty on plans of naval architecture, while he has shown himself a keen critic and experienced authority on naval affairs in the House of Commons. In 1877 he proposed without success the appointment of a Secretary of State for the Navy. Mr. R.'s services as a designer have been largely made use of by

the British and many foreign Governments, from whom he has received numerous orders of distinction. Among the ships in the Royal Navy constructed by him are the *Monarch* and the *Nep-tune*, the latter of which was purchased by the Admiralty from the government of Brazil for £600,000. He has written largely on naval and other subjects, *Our Ironclad Ships* (1869); *Our Naval Coast Defences* (1871); *Letters from Russia* (1875), &c.

Reed-Mace. See TYPHA.

Reef (from Old Eng. *reafian*, 'to seize'; 'what may be seized or pulled'), that portion of a sail comprehended between the head of the sail and any of the R. bands, four of which are usually in the topsail and two in the foresail and mainsail. By manipulation of the reefs the surface of the sails may be lessened on the increase of the wind. When all the reefs of the topsails are taken in, the vessel is said to be close-reefed. Sails are reefed by men on the yard, a dangerous operation in rough weather, which may be avoided by furling the sails by ropes from the deck under Cunningham's patent.—**R.**, a ridge of rocks rising as high as the surface of the sea (probably from the Icel. *hrifa*, 'a rake').

Reel' (named from the circling motion), a lively Scotch dance in common or jig time performed by two or more couples. The Danish *kroel* is somewhat similar.

Reel'-Winding Machines. Numerous attempts have been made to introduce automatic machinery for filling the spools or reels of sewing-thread, &c., an operation now chiefly done by girls. The machines proposed have generally been very complex in structure, costly, and liable to derangement; but one recently invented by Mr. Bash of Glasgow appears to be at once simple and efficient. It can be constructed by multiplication of parts to fill any desired number of reels at once, and it can be easily arranged to suit different sizes of thread, reel, &c. The apparatus fills the reel, nicks the side, cuts the thread, secures the loose end in the nick, and throws out the finished reel or thread automatically, leaving only to the attendant the duty of supplying the empty reel. It is being extensively adopted in the great thread factories.

Re-entering Angles (Fr. *Angles Rentrants*), or **Angles of the Flank**, in fortification, are the angle between the flanks of the bastion and the adjoining curtains, so named from their pointing towards the interior of the fortification.

Rees, Abraham, born at Llanbryn-mair, Montgomeryshire, in 1743, was educated for the Presbyterian ministry at Caermarthen and Coward's Academy, Hoxton. He was appointed mathematical tutor in that institution (1762), three years later was ordained to the pastorate of a Southwark congregation, and in 1786 accepted the chair of natural science in a newly-founded college at Hackney, which he held till 1795. He was a member of the Royal Society and a D.D. of Edinburgh at the time of his death, June 9, 1825. R.'s success as editor of the second edition of *Chambers's Cyclopædia* (4 vols. 1776-85), which he entirely recast, emboldened him to publish his own far larger *New Cyclopædia* (45 vols. Lond. 1802-20), and he was also for some years Dr Kippis' coadjutor in the *Monthly Review*, and author of *Practical Sermons* (1809), various social and political treatises, &c.

Reeve (Old Eng. *gerfæ*; see GRAF), the former title of the bailiff of a franchise or manor, who levied his lord's dues, acted as his deputy at the *folk-mot*, and could discharge certain of his judicial functions. Except in the Lowland Scotch *grive*, 'a farm overseer,' it now only exists in such compounds as *sheriff* (Old Eng. *scyr-gerfæ*), *port-reeve*, and *borough-reeve*.

Reeve, a term applied to the female Ruffs (q. v.) which are captured along with the male birds, and sent in large numbers from the Lincolnshire fens and marshes to the London market.

Reeve, Clara, an English novelist, born at Ipswich in 1738, was the daughter of a clergyman, with whom she read through Rapin's *History of England*, the Greek and Roman histories, and Plutarch's *Lives*, while a mere child. In 1762 she displayed her learning by translating from the Latin Barclay's fine old romance of *Argenis*, under the title of *The Phanix*. Five years afterwards appeared *The Champion of Virtue*, which in the second edition changed its name to *The Old English Baron*. The authoress in the preface informs us that the romance is 'the literary offspring of the *Castle of Otranto*.' It uses much

of the supernatural machinery Walpole and Mrs. Radcliffe were so fond of, but is much more verbose and feeble. Her other books, quite forgotten, are:—*The Two Mentors* (1783); *The Progress of Romance* (1785); *The Exile* (1788); *The School for Widows* (1791); *Plans of Education* (1792); *Memoirs of Sir Roger de Clarendon* (1793); *Destination* (1799), and *Edwin, King of Northumberland* (1802). Miss R. died at Ipswich 3d December 1803. See Sir Walter Scott's *Biographical Memoirs* (Edin. 1852).

Reeves, Sims, the greatest English tenor of modern days, was born at Woolwich in 1821. While still in his teens he became organist and instructor of the choir in the church of North Cray, Kent. His teachers in singing included T. Cooke and Hobbs. He first came out as a baritone at Newcastle in 1839. After a course of study at Paris he proceeded to Milan, where he received lessons from Mazzucati, and appeared at the Scala in the part of Edgardo (tenor) in *Lucia di Lammermoor*. On 6th December 1847 he began an engagement at Drury Lane, during which he sang in *Lucia* and in *Balle's Maid of Honour*. He appeared at Her Majesty's Theatre in 1848, and at Covent Garden in 1849. In the spring of 1851 he confirmed the reputation he had gained in Italy and in England by an appearance in Italian opera in Paris. He was the leading tenor in the English Opera Company at Covent Garden in 1860, when he took the original part of *Robin Hood* in Macfarren's work of that name. His most brilliant successes, however, have been gained in oratorios and the concert-room, and for many years no great musical festival was considered complete without his presence. In his best days his voice possessed a splendid quality and strength, and the brilliancy of his execution and artistic beauty of his style distinguished him as much as his vocal power. He rendered the most florid composition and the homeliest ballad alike with perfect grace and feeling.

Reference, in law. See ARBITRATION.

Referendaries, in the early European monarchies, were officers charged with the procuring, execution, and despatch of charters and diplomas. In France the Grand Referendary performed analogous functions to the Chancellor or Keeper of the Seals.

Refin'ing, as applied to metals, indicates the separation of a commercially pure metal from its regulus, or any impure compound. The operation varies according to the nature of the metal and compound dealt with, and for details see under the various metals, especially IRON, GOLD, and SILVER. See also ASSAYING.

Reflection is the change of direction which a ray of light, radiant heat, sound, or other form of radiant energy, experiences when it strikes upon the surface of separation of two media, and is thrown back into the same medium from which it approached. When the reflecting surface is plain, the direction of the reflected ray makes with the normal to the surface the same angle which the incident ray makes with the same normal; or, as it is usually expressed, the angles of reflection and incidence are equal. When the surfaces are curved the same law holds (see OPTICS). In all cases of R., the energy of the ray is diminished, so that R. must always be accompanied by absorption. Not only so, but absorption probably precedes R. Most bodies are visible by light reflected from their surfaces; but ere this has taken place the light has undergone the modification which gives it the colour peculiar to the bodies viewed. When light impinges upon the surface of a denser medium, part is reflected, part absorbed, and part usually refracted (see REFRACTION). But for a certain angle depending upon the refractive index of the refracting medium no refraction takes place. This angle is called the angle of *total R.*, since all the light which is not absorbed is wholly reflected. For the phenomena of reflected sound, see ECHO. See also UNDULATORY THEORY and TELESCOPE.

Reform', in English, is now commonly restricted to signify any change in the regulations of Parliamentary representation treated under HISTORY OF ENGLAND. Properly, however, the word has a much wider meaning, and is appropriately applied to any re-arrangement, legislative, religious, or even literary, which either brings back an older order of things which has been fallen away from, as did the reforms of Livius Drusus and the Gracchi in Roman history, or reconstructs the present

order in an entirely new form, as did the Solonic R. in Greece. Taking the word in its widest sense, we may say that it is the distinguishing feature of the English constitution to have grown by the more gradual and continuous process of R., and in but a small degree to have been hurried forward by the intermittent and volcanic action of revolution.

Reformation, The, is the name applied by Protestants (q. v.) to the Disruption of the Roman Catholic Church which took place in the 16th c. This revolution is sometimes regarded by Protestants as an isolated event brought about by the genius of Luther; as an effort to purify a Church which was rotten to the core, root and branches, and entirely opposed to any reform; and the effects of which were the spread of learning, the diffusion of pure doctrine and morals, and the gain of political and religious liberty. The fact is, however, that the R. was only one phase of that regeneration of Europe which began in the 15th c. and has been called the Renaissance (q. v.); and the work of Luther was not to bring about a R. of which there had been no signs before, but to apply the match to a train which had been in preparation for a century or more within the Church herself. One who desires to form a correct impression of what the R. was in its nature and effects has to remember that of the host of pamphlets called forth by every discussion in the prodigious intellectual activity of the time, almost all those on the Roman Catholic side were destroyed at the triumph of Protestantism, as indeed it was often with difficulty that they could be got printed; and that the R. cannot be fairly judged from the narrative of one side alone. The causes of the R. can only be properly understood by considering the previous condition of Europe and the change which at the time passed over the general mental condition of the people.

In the 15th c. the spirit of humanity began to awake, after a ten-centuries sleep of sluggishness, stupidity, and superstition. And as humanity was then represented by Europe, so the leading nation of Europe was Italy. In that country a long period of independence and comparative prosperity in trade and commerce had produced a greater accumulation of wealth than in any other country, and a consequent superiority in learning, arts, and general culture. Accordingly, it was in this country that the harbingers of the great intellectual revival appeared—Dante (q. v.), Petrarch (q. v.), and Boccaccio (q. v.).

The grand characteristic of the Renaissance was the twofold discovery by man of the world and of himself. The special sphere of the R. was that part of the Renaissance connected with the discovery of Man in his spiritual relations; or which exhibited in the domain of religious thought what the Renaissance elsewhere did in the spheres of Discovery, Science, Art, and Scholarship. In the restricted sense of the Protestant movement, the R. falls to be considered in a threefold aspect: political, intellectual, and moral.

Political.—There can be no doubt that the success of the R. as a disruption of the Church depended on its political relations. Throughout the greater part of the Middle Ages the Christian countries of Europe were virtually governed by the Popes as the superiors of all the secular clergy, and the countless orders of monks and friars. The power wielded through this ecclesiastical organisation was enormous, and at first was beneficial for civilisation, by fusing the people to some extent into a single community, and by counteracting the other influences which all tended to division and isolation, thus saving Europe from anarchy and lawlessness. But however beneficial the supremacy of the Popes may have been for a time, the mind of Europe began to rebel against it. The growth of nationalism and the conception of monarchy in its modern form were both hostile to it. Laymen generally, from the highest to the lowest, began to kick against the universal clerical control which was exercised over them. The Pope assumed the post of arbiter in national quarrels, and claimed the right to crown and dethrone kings at his pleasure. As regards the people generally, the clergy alone not only baptized, married, and granted or refused Christian burial, but had virtually the disposal of a dead man's property, as his will had to be proved in an ecclesiastical court. But that which was always made the worst complaint against the Papacy was that so much money was drained out of the different countries to go to Rome. This was made a handle of by all the Reformers—Wiclif, Huss, Luther, &c. And it was the weakest handle they had, for it was an appeal to the most sordid and selfish elements of human nature.

This circumstance alone would cast some suspicion on the motives of those who were so eager for a reform which relieved them of the taxes required for the support of the Church. Even the clergy joined the laymen in calling abuses the dues which the Church received, while yielding to the exactions of princes; abuses of this kind having been as much due to lay patrons as to the Pope.

This reaction against the Papacy, the climax of which was the essential political feature of the R., dates from the 12th c. In England from before 1164, when the Constitutions of Clarendon were passed under Henry II., there had been a disposition to resent ecclesiastical interference in the affairs of the kingdom. When the Popes at Avignon became the creatures of the French king, their influence in England still further waned; and under Edward III. (1327-77) 'Parliament vindicated the right of the state to prohibit the admission or execution of Papal bulls and briefs within the realm by the statute of *Præmunire*, and denied the Papal claim to dispose of benefices by that of *Provisors*.'

In France the contest began under Philippe le Bel, in the dispute which arose between that monarch and Boniface VIII. (1295) regarding the exportation of money from France to Rome, the right of Philippe to impose taxes on the clergy, and the rights of the laity generally in relation to the clergy. The pretensions of the Pope to supremacy over Philippe in secular matters were met with a determined resistance by the whole French nation. A similar effect was produced in Germany when John XXII. attempted to maintain his supremacy over the empire, and to deprive Ludwig of Bavaria of his crown in order to confer it on the King of France (1324). The result was that in 1338 the electoral princes solemnly declared that the King of the Romans received his appointment solely from the electoral college. Now, sovereigns in their contests with the Popes, or rival princes in their contests with each other, were always glad to make use of any spiritual opposition to the Papal power; as, e.g., Charles VIII. of France made use of Savonarola. So the Hussites derived an adventitious political importance from the enmity existing between Bohemia and Austria; and the support which Luther received from some of the German princes turned on the hereditary enmity between Austria and France, produced by the marriage of Maximilian I. to the heiress of Burgundy (1477). Maximilian, in writing on one occasion to the Elector of Saxony regarding Luther, said 'there might come a time when he would be needed.' At the time when Luther was beginning to make himself heard, the Elector of Saxony had a quarrel of his own with Albrecht, Archbishop of Mainz, and the Pope, because a bastard son of his had been refused admission to an ecclesiastical benefice. The way that the quarrel of Henry VIII. with the Pope regarding the divorce of his wife furthered the R. in England is well known. Such were the general, and some of the particular, political causes which led up to the R. Add to the former that a new power on the side of freedom had arisen among the people by the enfranchisement of city corporations. Burgesses had risen in social status, and having been freed from the yoke of feudalism at home, would be little inclined to brook foreign control of the same kind. Besides, the general spirit of independence was greatly fostered by the diffusion of popular literature by means of the printing-press (invented 1438). Works descriptive of the rights of the people, of the intellectual and civil thralldom in which their fathers had been kept, and of the means of redress, were freely circulated, and read with avidity. This agitation for civil liberty Luther turned against the existing religious institutions. His writings bore such titles as *Christian Freedom*, *Bondage of Babylon*, &c.; and his constant watchword was 'Liberty.'

Intellectual.—From about the middle of the 11th c. the scholastic philosophy and theology had been completely dominant in the Church. A new era began when the long-neglected study of the classic authors was resumed at the end of the 14th c. The intelligent and critical study of Latin, Greek, and Hebrew exposed the ignorance of the Schoolmen, and the 'Humanists,' as the classical scholars were called, turned to ridicule the barbarous style, hair-splitting subtleties, and trivial polemics of the theologians, as well as the generally profitless and meaningless methods of the whole education of the time, which had all a clerical tone. Even the science of the time was settled by texts of Scripture; e.g., it was held on this ground, that the earth was flat and the centre of the universe. Thus the discovery at this time of America (1492) and the rotundity of the earth dealt a great

blow to the influence of the Church, by proving that her teaching was false in this particular. Copernicus explained his view of the solar system in 1507. An instrument which did a great part of the work in educating and enlightening the people which is generally ascribed to Luther or to the R. was the printing-press (1438). By means of it books gained a circulation which they could never have had in MS. By the end of the 15th c. it was at work in most of the large towns in Italy and France, and between 1455 and 1536, 22,932,000 volumes were printed by the Popes and by Roman Catholic princes and sovereigns, the patrons of learning, arts, and sciences. Not only were the classics and copies of the Scriptures in the original—Hebrew and Greek—provided for scholars, but copies of the Scriptures in the vernacular for the people. Before the R. upwards of twenty versions had been made into the different modern European languages—Italian, French, Spanish, Belgic, German, and English. Again, universities were founded everywhere (ten in Germany alone between 1403 and 1506), in which professors lectured in the vernacular instead of the old learned language of Latin.

The effect of all these enlightening influences was to produce, in reference to the Papacy and the creed of the Church, a leavening of that spirit which in modern times has received the name of Rationalism (q. v.). It was manifested at that time 'in the irrepressible aspirations of the human mind to establish the right of every individual to judge for himself in matters most deeply affecting his welfare and peace of mind—that is, to follow the decisions of his reason and the dictates of his moral sense, and thereby to emancipate himself from the yoke of ecclesiastical systems and the thralldom of theological creeds.' This spirit was one of the influences at work in the minds of the Reformers of the 16th c.; but it was not the only one, and it was not the strongest one. They had found deliverance from the Pope and the dogmas of the medieval Church by the help of the Scriptures, and these were now invested with a quite new authority. An infallible Book was substituted for an infallible Church, and dogmatic tests of orthodoxy were enforced as rigidly as in the Mother Church—a practice entirely at variance with the true Protestant principle of liberty. The immediate effect of the R. on learning was on the whole detrimental. The Reformers not only discouraged classical and scientific studies, and denounced them as a snare of the devil, but even Biblical criticism was denounced. The facts are very significant that, whilst at Venice alone, before 1559, sixteen editions of the Hebrew Bible had been printed, there was not an edition published in Protestant Germany till the close of the century; and while at Paris alone, before 1551, ten editions of the Greek New Testament had been printed, there was not one produced in Protestant Germany for forty years after the R. The general condition of the universities became deplorable. They soon became noted for nothing but the pride, laziness, and unbudding licentiousness of the professors, and the debauchery, gambling, blasphemy, and indecent language of the students. So flagrant did this become that parents feared to send their sons to attend them. The number of students at the University of Erfurt, *eg.*, fell from 311 in 1520 to 14 in 1527.

Moral.—The struggle between purity and corruption in the Church was no new thing in the 16th c. The desire to escape from various forms of degeneracy gave rise to almost all the countless orders of monks and friars which were founded in the Middle Ages. But these societies, each in its turn, fell into the very abuses which their founders desired to avoid; and as we approach the time of the R. a tendency becomes apparent to form for this reason sects outside of, or even hostile to, the Church—*eg.*, the Cathari (q. v.), Waldenses (q. v.), Albigenses (q. v.), &c.—all distinguished by a common renunciation of the authority of the priesthood. By the beginning of the 16th c. the whole of Christendom was crying out for a reform of the Church. The sees being mostly filled by simony, many of the bishops were utterly unfit for their office, the duties of which they neglected for various reasons. The chief of the prelates indeed were also secular princes, who sunk their spiritual functions in their secular character. The clergy, thus left very much to themselves, became illiterate and immoral, while practising on the people similar exactions to those practised on themselves by their superiors. Grievous complaints of these abuses had been carried to Rome from before the beginning of the 15th c. A vigorous but unsuccessful attempt was made, at the instance of

the Faculty of Theology at Paris, in the Councils of Pisa, Constance, and Basel (1409–1443), to obtain a reformation in the morals of the clergy and the administration of the Church. Efforts in the same direction had been made by various Popes—Nicholas V. (1447–55), Sixtus IV. (1471–84), Innocent VIII. (1484–92), Julius II. (1503–13), and Leo X. (1513–22). By the last-named pontiff various enactments were made for priests, bishops, and cardinals, regarding their learning, mode of life, and discharge of duty. It must be admitted that until the R. these efforts had very little effect; and so far from any attempt having been made to check the abuse which both Luther and Zwinglius almost simultaneously made the *casus belli* of their opposition to the Church—namely, that of Indulgences (q. v.)—it was carried on at the instance, and in order to fill the coffers, of the Pope.

In connection with this aspect of the subject it is remarkable, although it was not altogether unnatural, that the immediate effect of the R. was to produce a kind of libertinism among Protestants. It is startling to read the accounts given by the Reformers themselves of the corruption of morals among the people. Luther declared that men were more covetous, hard-hearted, corrupt, licentious, and wicked than of old under the Papacy. So great was the corruption in Wittenberg that he wished to leave it for ever, and to see his little daughter die before him. But the despondency that often seized the great Reformer need not affect the judgments of those who live more than three centuries later in time, and who can read in the pages of history the vast and various benefits which the R. ultimately conferred on Europe and the world. A change which brought men face to face with God, which connected the liberty of private judgment with responsibilities of eternal moment, which obliterated all the inequalities of life and character in the universal need of a personal salvation, and compelled all Christians, high and low, rich and poor, lay and cleric, to recognise the necessity of following in the footsteps of Christ, was an enormous change for the better. The conceptions of life and duty were immeasurably enlarged and infinitely intensified. A fresh vigour, a new vitality, was given to men's nature; the individual rose in dignity and worth; and in spite of the narrowing influences of mere creed-worship, a moral energy was aroused that has gone on increasing from age to age, and the ultimate effects of which it is impossible even yet to foresee. The Church of Rome itself has shared in the good effects of the R., which has set up a common standard of moral life for Christendom that no religious communion can ever again afford to neglect or despise. The details of the history of the R. in the various countries of Europe will be found under LUTHER, ZWINGLIUS, FAREL, CALVIN, WICLIF, HENRY VIII., CRANMER, PATRICK HAMILTON, GEORGE WISLIART, JOHN KNOX, &c. See Symonds' *Renaissance in Italy* (Lond. 1875 *seq.*); Häusser's *Geschichte des Zeitalters der R.* (Eng. trans. 1873); D'Aubigné's *Hist. de la R.*; Dollinger's *Die R.* (Regensb. 1848); Gieseler's *Lehrbuch der Kirchengeschichte* (Eng. trans. 1855); Mosheim's *Institutiones Hist. Eccl.* (Eng. trans.); Fisher's *R.* (Lond. 1873). For England specially, Foxe's *Book of Martyrs* (1563); Burnet's *History of the R.*, &c. Reformatory Schools are institutions founded for the purpose of reclaiming children who have already begun a career of vice or crime. They are intended not only to inculcate moral principles, but to provide a practical knowledge of industrial pursuits. They are identical in character with certified industrial schools, and differ from ragged schools in so far as they are maintained by the State, and only receive children or youths under judicial sentence. The history of R. S. on the Continent begins with the Reformation, when workhouses were founded in Amsterdam, Leyden, Hamburg, Lubeck, and other cities, for the purpose of checking vagrancy. Every workhouse had a special department, in which refractory children were placed for discipline. Parents could send obstinate or froward children either gratuitously or for a small charge, which entitled them to certain privileges. The benevolent movement thus begun led soon to the establishment of houses of correction, industrial schools, orphanages, and kindred institutions, all differing somewhat from the R. S. and from each other, but all agreeing sub-

stantially in purpose. The originator of the modern R. S. system in Germany was J. D. Falk, the philanthropist, and founder of 'The Friend in Need' Society, which, by the establishment of the Lutherhof at Weimar in 1818, provided homes for 300 children, to whom elementary instruction was given in religion and industries. About the same time similar institutions at Overdyk and Düsseldorf were founded by Counts Adalbert and Werner von der Rieke, and these are still in existence, with an average roll of 300 children. The R. S. at Beuggen, Baden, founded in 1816, was the first of the kind in the S. of Germany. That in Berlin was opened in 1825, and has been greatly enlarged recently. It was followed by the organisation of such schools at Memel, Frankfurt, Posen, Stettin, and Königsberg. The foundation by the State of houses of correction has, however, caused a number of these institutions to disappear. In Switzerland there were in 1877 as many as 44 farm and R. S., with 1543 pupils. Perhaps the most celebrated of all Continental R. S. was the Rauhes Haus, formed in Hamburg by J. H. Wichern in 1833. With this school was connected a small farm near Hamburg, and here the 'family plan' was developed, a little village soon springing up with its church, schoolhouse, workshops, and gardens. The fundamental idea of the Rauhes Haus was that it should be at once a training school and an institution for preparing missionaries. The heads of families, teachers, overseers, formed a religious brotherhood, the members of which, after an apprenticeship in the simple community, went out into the world as ministers to the poor. From its foundation till 1867 the Rauhes Haus had received and educated 800 children, the average yearly attendance being 120. Its influence has been very great, the family plan having been adopted in various parts of Russia, Switzerland, France, Belgium, Sweden, England, and the United States. The first R. S. in England was founded near London by the Philanthropic Society in 1788. Two others, one in Warwickshire (1818), the peculiarity of which was out-door labour, and another established (1830) by Captain Brenton, who held that no person under sixteen years of age should be sent to prison, were allowed to collapse for want of funds. In 1834 the Victoria Asylum for girls was opened at Chiswick, and in 1838 a separate prison was added to that at Parkhurst for persons under sixteen, in which the discipline was reformatory. The institution founded at St. George's-in-the-Fields by the Philanthropic Society having fallen off somewhat, it was removed in 1850 to Redhill, in Surrey, where on the family plan it is now the largest of English reformatories. Since then, important schools have been founded at Harewicke Court, Kingswood, Stoke Farm, and Saltley. In 1854 the R. S. Act was passed, authorising magistrates to commit to R. S. youths under sixteen (in Scotland under fourteen) for not less than two, or more than five years. The English law divides schools into two kinds—R. S. proper, intended for correction, and industrial schools, intended for prevention, admission to either kinds being determined by differences of age and previous criminality. In 1866 the laws relating to these were consolidated and amended. In 1873 Great Britain had 45 reformatories for boys and 20 for girls, the former with 4424 inmates, and the latter with 1151. In the United States there were in 1877 as many as 66 reform institutions, some under State, others under municipal control. The oldest and largest is that on Randall's Island, New York, which was founded in 1825, and has an average of 800 inmates. See INDUSTRIAL SCHOOLS and RAGGED SCHOOLS; also the *Proceedings of the International Prison Congress*, held in London in 1872, and *Reports on Certified Industrial and R. S.* (20 vols. 1856-77).

Reformed' Churches, in its widest sense, is the title applied to all the religious communities which separated from the Roman Catholic Church in the 16th c.—Lutheran, Zwinglian, and Calvinistic; but Lutheran writers use it to denote all which did so except their own. In this latter sense the R. C. would mean those of England, Scotland, Holland, Switzerland, France, Ireland, and N. America. The Reformed Church of Germany is Zwingli-Lutheran rather than Calvinistic, and holds by the Heidelberg Confession.

Refraction is the change of direction which a ray of light, heat, &c., undergoes in passing from one medium to another. When a ray passing from a vacuum into any medium is refracted, the sine of the angle which the refracted ray makes with the normal to the surface of separation at the point of refraction

bears to corresponding sine for the incident ray a constant ratio, which is called the refractive index for the medium. (See OPTICS, UNDULATORY THEORY, TELESCOPE.) This refractive index, however, is different for different rays of light, so that R. of ordinary white light is necessarily accompanied by separation into different coloured rays. See SPECTRUM ANALYSIS.

In certain media the refracted ray is split into two distinct pencils. This phenomenon of *Double R.* was first observed with Iceland spar by Erasmus Bartholinus, whose experiments were published at Copenhagen in 1669. The two rays are called the ordinary and extraordinary rays, because the one follows the ordinary laws of R. while the other does not. It is a property possessed by all crystallised minerals except those belonging to the cubical system. In most cases, however, the separation of the two rays is too small to be directly observed, but its existence is proved by certain phenomena which result from the mutual action of the two pencils. (See POLARISATION.) Huygens was the first to discuss theoretically the nature of double R.; and in the hands of Fresnel the theory became almost complete. In following out this theory to its consequences, Sir W. R. Hamilton came upon two remarkable cases of double R. which had hitherto escaped notice. He found that, in certain circumstances, a ray of light emerging from or passing into a doubly refracting crystal was split up into a *cone* of rays. The two cases are distinguished as external and internal conical R. This prediction from theory was tested experimentally by Lloyd, and fully corroborated even to its details, thus affording one of the most powerful arguments in favour of the undulatory theory. See Lloyd's *Wave Theory of Light*.

Refrain (Fr. *refrein*), the burden of a song—the portion repeated after each verse.

Refrigerants are medicines which diminish the heat of the body when unduly increased, produce a sensation of coolness, and quench thirst. They do not in reality diminish the temperature of the body, as may be ascertained by the test of the thermometer, but they cause a sensation of coolness and a refreshing feeling over the whole body. When applied externally, in the form of cooling or evaporating lotions to inflamed parts, the temperature of the part to which they are applied is actually lowered. R. are used in medicine in the treatment of febrile and inflammatory affections, their action on the stomach occasioning, sympathetically, a temporary reduction in the force of the circulation, and thereby allaying morbid sensations of heat, thirst, and nausea. The following are the R. in most common use for internal administration: *Acetic acid* or *vinegar*, half an ounce to an ounce, diluted with 20 fluid ounces of water, forms a cooling drink, and may be taken *ad libitum*, unless where contra-indicated. In the proportion of one to three of cold or tepid water it may be applied by means of a sponge to the surface of the body, as an external refrigerant, in the treatment of most febrile and inflammatory diseases. *Citric acid* may be administered in the form of effervescing powders along with bicarbonate of soda or bicarbonate of potash, in the proportion of nine parts of the acid and eleven parts of the soda, or thirteen parts of the potash carbonates. Lemon-juice is also much employed in the preparation of effervescing draughts, with the alkaline carbonates, in the proportion of three and a half drachms of lemon-juice to twenty grains of the bicarbonate of potash. *Nitrate of potash* is administered in febrile affections in the form of *nitre whey*, prepared by boiling two drachms of nitre in one pint of new milk, and straining. It may then be taken in doses of from 2 to 4 ounces. Water at various degrees of temperature, snow, ice, and freezing mixtures, prepared with salt and pounded ice, are used as R. both in medicine and surgery, but more especially in surgery. Applied to the spine, they are useful in the treatment of the nervous diseases of women. See article HYDROPATHY.

Refrigerating Machines. See ICE.

Refrigeration of the Earth. That the earth is a cooling body is now an accepted truth in cosmic science. The fact upon which it is based is, that as we descend into the earth the temperature increases regularly by about 1° F. for every 60 feet. Consequently there must be a flow of heat outwards towards the crust through every isothermal surface throughout the mass, with a simultaneous radiation of heat from the surface into space, and this must continue as long as the earth is hotter

than space. Knowing the rate of increase of temperature with depth, and the thermal conductivity of the rocks near the surface of the earth, Sir William Thomson has calculated the quantity of heat which the earth radiates per annum, and with the aid of Fourier's analysis has worked backwards to a time when the conditions under which Fourier's equations applied no longer exist. In other words, the earth was not then a solid, but a molten mass quite unfitted for the existence of life as we know it. Here then is a superior limit to geological time, and this limit Thomson has fixed at 200,000,000 years. Thermal conductivity generally increases with temperature, so that the earth would probably cool much faster in past time than now. This consideration, according to Professor Tait, is sufficient to reduce the limit to 20,000,000 of years, and even then life would not be possible, since water could not exist as liquid till at least 10,000,000 years subsequent. See EARTH.

Refrigerator, an apparatus for the preservation of perishable articles of food by exposing them to a low temperature; an ice-safe. A R. for domestic use consists of a chamber having double walls, the exterior of wood and interior of metal generally, with a lining of some non-conducting substance between. Inside, shelves are fitted up for holding the provisions to be preserved, and in an upper compartment a quantity of ice is packed which considerably reduces the temperature of the currents of air circulating through the chamber. To keep wines or other bottled liquids cool, the cold water draining from the ice is caused to trickle over the bottles placed below. Allegretti's R. has an inside metallic chamber for meat or vegetables, which is surrounded at the sides and part of the top with an ice-chamber, and below is a cold-air passage; an outer double-walled case encloses the whole.

The name R. is also applied to an apparatus employed for speedily reducing the temperature of liquids; it is used in breweries for cooling worts, and is also applicable for dairy purposes. In old forms of the brewer's R. the worts are run through a length of metal tubing which is surrounded by cold water. Many disadvantages attend this method of cooling, and it is generally being supplanted. In improved forms of R., such as Lawrence's of London, the liquid to be cooled flows over the outside of a series of metal pipes or deeply corrugated sheets, through or between which cold water passes.

Refugee (Fr. *réfugié*), one who, in times of religious persecution or of political commotion, flies to a foreign country for liberty or safety. The name was first given to those Protestants who fled from Holland to escape the persecution of Alva in 1567, but is now applied especially to the French Huguenots who found an asylum in England, Holland, and other countries on the revocation of the Edict of Nantes by Louis XIV. in 1685. They belonged chiefly to the industrious *bourgeois* class, and carrying with them their capital and the knowledge of their crafts, were everywhere warmly received. Most of those who settled in England anglicised their names, so that their posterity cannot now be distinguished, but several who belonged to the higher classes obtained high honours in their adopted country, and have had descendants who have been elevated to the peerage. The French Revolution drove many refugees to England, which enjoys the glory of being the peculiar home for refugees of every class and country. See Erman and Reclam, *Mémoires pour servir à l'Histoire des Réfugiés Français* (9 vols. Berl. 1782-1800), Weiss, *Histoire des Réfugiés Protestants* (Paris, 1833), and Smiles, *Huguenots in England and Ireland* (Lond. 1867).

Regal, or **Rigole**, a small portable organ formerly much in use, fitted usually with one, but sometimes with a double row of pipes. Its principal function was to support treble voices.

Regalbuto, a town of Sicily, province of Catania, situated on a hill commanding a view of Mount Etna, near the right bank of the river Salso, 17 miles E. of Leonforte by the highroad to Catania. It has a fine cathedral. Pop. (1874) 9429.

Regalecus, a genus of *Teleostean* fishes, belonging to the family *Trachipteridae*, and including the curious Tape-fish (q. v.) (*Regalecus Baskii*), so named from its long thin shape. The body is much compressed in this genus; the ventral fins are long and attenuated, and the dorsal fin is spiny.

Regalia (Lat. 'royal things'), the ensigns of royalty, more especially those used at a coronation. The old R. of England,

before the Reformation intrusted to the monks of Westminster Abbey, having been destroyed in the Civil War, new ensigns were made for the coronation of Charles II. These, now exhibited in the jewel-room in the Tower of London, include the royal crown and sceptre (with the cross), the verge or rod (with the dove), the 'staff of Edward the Confessor' (made for Charles II.), the two sharp 'swords of justice,' and *Curtana*, the blunt 'sword of mercy,' the anointing-spoon and ampulla for the coronation oil, the armilla, the 'spurs of chivalry,' and certain vestments. With these are exhibited the lesser insignia of a queen-consort, the golden crown of the Prince of Wales, and Queen Victoria's state-crown of silver and diamonds.

The R. of Scotland, including the crown (dating from Robert the Bruce), adorned with alternate crosses and *fleurs-de-lis*, the sceptre (from James V.), and the 'sword of state' (presented to James IV. by Pope Julius II. in 1507), were, during the Civil War, taken from the crown-room of Edinburgh Castle by the Earl Marischal to his castle of Dunnottar, at the siege of which by the Parliamentary army they were secretly conveyed to the manse of Kinneff. From the Restoration to the Union the R. of Scotland were again kept in the crown-room, where from the Union till 1818 they were hidden away in a chest, though popularly believed to have been secretly transferred to the Tower of London. On the 4th February 1818, by permission of the Prince Regent, they were taken from their concealment, and they are now intrusted to the officers of state for Scotland, and exhibited in the crown-room, along with certain other insignia bequeathed to George IV. by Cardinal York, and lodged in Edinburgh Castle (1830) by William IV.

Regality, a territorial jurisdiction which formerly existed in Scotland. It was conferred by the crown, and those receiving the right were called *Lords of R.* Their civil jurisdiction was equal to that of the sheriff, but their criminal jurisdiction was much greater, being, except in case of treason, equal to that now exercised by the *Justiciary Court* (q. v.). The jurisdiction was abolished by 20 Geo. II. c. 50. The analogous jurisdiction in England was called a *Palatinate*. See COUNTIES.

Regatta (Ital.), a name given by the Venetians to a grand fête in which a chief incident was a contest of the gondoliers. It is now applied generally to all rowing or sailing matches, but more especially to yachting races. See YACHT AND YACHTING.

Regelation, the name given by Faraday to the property possessed by ice at 0° C., of gradually joining itself to another fragment at the same temperature with which it is placed in contact. Faraday explained the phenomenon by supposing that the film of liquid between the two pieces of ice assumed the solid state because of the proximity of particles in this state. This, however, is hardly an explanation, since it is based upon an assumption by no means self-evident. Forbes based his explanation upon an even more doubtful assumption, viz., that ice was essentially colder than water, so that there was always a transfer of heat from the water to the ice. The effect of this was to make the ice semi-fluid at the surface; and, therefore, when two pieces were placed in contact, the film of water between them parted with its heat to the ice on both sides until it cooled sufficiently to freeze, while the heat it gave off was not sufficient to melt the ice. The explanation proposed by Professor J. Thomson is founded upon the truth, theoretically discovered by himself, that the freezing point of water is lowered by pressure. Hence if two slabs of ice are present together, the ice will melt at the points of greatest pressure. Now ice contracts when it liquifies and at the same time absorbs heat. The pressure will be at once relieved, and the cold produced will re-freeze the water. The points of greatest pressure will thus be continually shifting until the union is complete. Faraday and Forbes both objected to this explanation, upon the ground that R. took place between two pieces of ice which were suspended side by side so as to just touch and no more. Here, they maintained, there was no pressure; but J. Thomson showed that the capillary action of the film of water between them was sufficient to produce the requisite pressure—an explanation supported by the fact that R. cannot take place between dry slabs of ice (*i.e.*, at a temperature lower than the freezing point) without external pressure being applied. See GLACIERS.

Regeneration (Lat. 'new birth'), among the Jews, denoted the change of status which a heathen proselyte underwent on joining the Jewish community; he was said to be 'born again.' In Christian theology it is the name given to the change from a carnal to a Christian life (cf. John iii. 3). The term R. in this sense only occurs once in the New Testament (Tit. iii. 5); in Matt. xix. 28 it has a different meaning (see PALINGENESIA). But the idea is one of the most fundamental in the Pauline theology. What the apostle indicates by it is a change so complete that the new state is in every respect the opposite of the old, and that, as regards spiritual matters, nothing passes from the old to the new (cf. 2 Cor. v. 17). The same idea occurs in the epistle under various figures. (1) Various passages represent it as a spiritual creation, which is attributed sometimes to Christ and sometimes to God, forming a parallel to the physical creation or the natural birth of man (cf. 1 Cor. viii. 6, Gal. vi. 15, Eph. ii. 10, iv. 24, Col. iii. 10, &c.). (2) Others, as a renewal; the Christian becomes a new man, or a series of bad qualities are laid aside like a garment, and a series of good ones put on like another (Rom. vi. 6, xii. 2, Eph. ii. 15, iv. 22-24, Col. iii. 9, 10, &c.). (3) And a third class, as a metamorphosis; the Christian must so closely resemble Christ as to be changed into his image (Rom. viii. 29, xii. 2, xiii. 14, Gal. iii. 27, Col. iii. 10, &c.).

In the doctrine of the Church of Rome, R. is synonymous with Justification (q. v.), which includes (1) the removal of the guilt of sin; (2) purification from inherent moral corruption; (3) the 'infusion of new habits of grace;' and (4) adoption; and the instrumental cause of which is the sacrament of baptism. In that of the Reformed Churches (q. v.) it is 'an act of the almighty power of God,' which, without effecting any 'change in the essence or acts of the soul,' communicates a new principle of life. It is the Effectual Calling of the Westminster Confession and Catechism, and includes Conversion. In the Church of England, besides those who hold the Reformed and those who hold the Romish doctrine of R., there are some who make a distinction between Conversion and R., holding the latter to be a grace which accompanies baptism; while others regard it merely as an external change of status accompanying baptism. See Reuss, *Hist. de la Theol. Chrétienne* (Strasb. 3d ed. 1864), Hodge, *Syst. Theology* (Edin. 1873).

Regensburg, or **Ratisbon** (Lat. *Reginum* or *Ratisbona*), the chief town of the province of Oberpfalz and R., Bavaria, stands on the S. bank of the Danube, opposite the influx of the Regen, 65 miles N.E. of Munich by rail. It is situated in a wide and fertile valley, 1000 feet above the sea-level. A stone bridge of fifteen arches (finished 1146) connects it with its suburb *Stadt am Hof*. It presents a very medieval appearance with its ancient fortifications, narrow and crooked streets, and high-gabled houses. Among its most notable buildings are the Gothic cathedral of St. Peter (1275-1634), 306 feet long by 125 broad and 132 high, with a magnificently sculptured double portal, fine stained glass windows, remarkable monuments and elegant open towers, completed 1860-70; the Church of St. James of Scotland, dating from the 12th c., and of pure Byzantine architecture; the fine old Rathaus, partly of the 14th c., formerly the place of meeting of the German Diet; and the palace of the Prince of Thurn and Taxis. About 6 miles E. of R. is the magnificent Walhalla, or German Temple of Fame, founded by King Ludwig in 1830, and completed, from designs by Klenze, in 1842 at a cost of £67,000. A Doric edifice of grey marble, resembling the Parthenon, and surrounded by 52 fluted columns, it stands on a hill 323 feet high overlooking the Danube. It contains the 'Victories' of Rauch (q. v.), and 101 busts of famous Germans. R. is the seat of a bishop, and possesses in all 13 Catholic and 3 Protestant churches. It has several breweries and distilleries, and considerable manufactures of beetroot sugar, faience, candles, soap, and gold, silver, steel and brass ware. In 1853 it was made a free port, and has now considerable shipbuilding industry and extensive river trade in corn, wood, and especially salt. R. is one of the oldest towns in Germany. It was the *Castra Regina* of the Romans, and was a commercial station of importance in the 2d c. Its bishopric was founded in 740. Friedrich Barbarossa made it a free town, and from the 11th to the 15th c. it was the most populous and prosperous city of Germany. In the Thirty Years' War it was taken and retaken several times by the contending parties.

From 1663 to 1806, with only two interruptions (1713-14 and 1740-44), it was the seat of the Imperial Diet. It suffered severely in the five-days' battle fought in its neighbourhood in 1809. After several political vicissitudes in the Napoleonic times it was ultimately made over to Bavaria in 1810. Pop. (1875) 31,487.

Re'gent is the name given in England and France to one who without being king exercises kingly authority during the minority of the proper sovereign, during his absence from the country, or when he is incapacitated from any cause for the discharge of his royal duties. Other names have been used to designate the office. John, the brother of King Richard, acted as R. under the title of *summus rector totius regni*, while that monarch was fighting in the Holy Land; Somerset was R. under the title of 'Protector' during the minority of Edward VI., but the regency of the Prince of Wales (afterwards George IV.) during his father's insanity has made the name R. familiar to Englishmen.

Re'gents, in the medieval universities. Newly made M.A.'s had to teach their subject (*regere scholas*) for two years, during which period they were styled 'necessary R.' Afterwards they might teach or not as they pleased, and were therefore called *regentes ad placitum*. Gradually, however, the regents' functions were superseded by those of the Professors' (q. v.).

Reggell'o, a town of Italy, in the province of Florence, 16 miles E.S.E. of that city. Pop. (1874) 11,000.

Reggio (*Rhegium Julii*), called R. di Calabria to distinguish it from R. nell' Emilia, is the capital of the S. Italian province of R. di Calabria, and is situated on the Faro di Messina, 297 miles S.S.W. of Taranto by rail. Behind is the imposing wooded range of Aspromonte, the highest point of which, Montalto (6907 feet), is 4 miles distant. The town has environs of the most beautiful and varied scenery, and has a noble view of the Sicilian coast, with Mount Etna in the distance, and Messina 4½ miles off. As the old town was almost entirely destroyed by the earthquake of February 1783, the streets present a modern appearance. The finest is the Corso Borbonico, 3050 feet in length, which intersects the town from N. to S., and is adorned with many fine buildings. R. is an archiepiscopal residence, and has a fine cathedral rising in the midst of olive and orange groves. It has several educational institutions and an hospital. It manufactures linens, silks, essences, and scented waters. Pop. (1874) 20,855. R. was originally a colony from Chalcis in Eubœa, and was founded B.C. 723. It rose rapidly, and attained to great power under Anaxilas and his two sons (494-461 B.C.). It was destroyed by Dionysius the Elder (387 B.C.), partly rebuilt by Dionysius the Younger, and joined to Rome after the Social War. In 410 A.D. it marked the limit of the progress of Alaric, and in 549 it was taken by Totila. Destroyed in 918 by the Saracens, and in 1005 by the Pisans, it was taken by Robert Guiscard in 1060. In 1552 and 1597 it suffered severely from the Turks, and in its vicinity Garibaldi was taken prisoner by the Italian general Pallavicini, 29th August 1862.

Reggio (*Regium Lepidi*), distinguished from the preceding as R. nell' Emilia, is situated on the right bank of the river Crostoli, 96½ miles S.E. of Milan by rail. It has broad, well-built streets, flanked with arcades. The finest squares are the Piazza Maggiore and Piazza Minore, the former containing the cathedral of the 15th c., and the Municipio, near which is the house (still shown) in which Ariosto was born, and the latter, the church of S. Prospero, erected in 1504. Other buildings are the Teatro Nuovo, one of the finest in Italy; the church of the Madonna della Ghiara, with fine frescoes, built 1597; that of the Madonna della Concezione, a handsome modern structure; the Museo, containing the natural history collections of the famous Spallanzani (q. v.); and the Biblioteca Municipale, with 36,000 volumes, and MSS. of the 11th c. R. has manufactures of silk and hemp. Pop. (1874) 19,131.

Re'giam Majesta'tem is the title given to a collection of ancient laws, bearing to have been compiled by the order of David I., king of Scotland. There has been a controversy about the authenticity of the work, it being held by some authorities to be a compilation from the old laws of England, made by order of Edward I., with the view of assimilating the laws of Scotland to those of England.

Regillus, Lake, a small lake in Latium at the foot of the Tusculan hills, where the Romans under Aulus Postumius defeated C. Mamilius and the Latins in 496 B.C. Gell plausibly suggests that it occupied the site of a now drained volcanic crater at Cornufelle at the foot of the hill on which Frascati stands. The battle is the subject of one of Macaulay's *Lays of Ancient Rome*.

Regiment (Fr. from Lat. *regimentum*, 'rule' or 'government'), a body of soldiers consisting of one or more battalions of infantry or of several squadrons of cavalry, commanded by a colonel. It is the third subdivision of an army corps, several regiments going to a brigade, and several brigades to a division. In the British Army there are 3 regiments of Life and Horse Guards, 7 of Dragoon Guards, 3 of Dragoons, 13 of Hussars, 5 of Lancers, 3 of Foot Guards, 109 of Infantry, the Rifle Brigade, the Royal R. of Artillery, the Corps of Royal Engineers, and several Colonial and West India Regiments. The Scots Guards and the Coldstream Guards have two battalions each, and the Grenadier Guards have three battalions. All the line regiments from the 1st to the 25th have two battalions, and the others one, except the 60th (the King's Royal Rifles) and the Rifle Brigade, which have each four. The single battalion regiments are grouped in pairs under the Army Localisation Scheme, so as to form district brigades. Each battalion of infantry is commanded by a lieutenant-colonel, and is usually divided into 12 companies. Its peace complement varies from 600 to 800 men. A R. of cavalry, consisting of 8 troops, numbers in time of peace about 500 men. The army is placed upon a war footing, not by adding to the number of regiments, but by increasing the number of men in each. On the mobilisation of the 1st Army Corps in 1878, the war strength of each battalion of infantry was fixed at 31 officers, 50 sergeants, &c., 16 buglers, and 1000 men, or 1097 of all ranks, and of each R. of cavalry at 653 men of all ranks, with 480 troop horses, and 44 draught horses. The Royal R. of Artillery is composed of 31 brigades, 16 of which are horse brigades, and it numbered in 1877-78, 34,668 of all ranks. The Corps of Royal Engineers consists of 40 companies and 3 troops. In 1878 there were 135 infantry militia battalions, and 35 regiments of artillery militia. Most regiments are called after the county or district in which the men were originally enlisted. The regimental system can only exist in the case of standing armies. The Roman legions at first consisted of 4200 infantry (30 companies) and 300 cavalry. Each company was commanded by a first and second centurion assisted by two ensigns. In the days of Marius the number was 6000 men divided into 10 cohorts. In modern days regiments date from the fall of feudalism, and were first formed in France. Companies such as the 'Compagnies d'ordonnance' established by Charles VII. were ultimately grouped into regiments, which were made of nearly uniform strength, the battalion forming the tactical and the R. the administrative unit. The 1st Royal Scots, which was originally the Scottish Guard of the Kings of France, is said to have the oldest history of any R. in the world. The next oldest regiments in the British army are those of Life, Horse, and Foot Guards, the 2d Queen's and the 3d Buffs, which were the only troops maintained after the disbanding of the army of the Commonwealth. Charles II. added a few regiments to these, James II. raised 8 of cavalry and 12 of infantry, William III. 3 of cavalry and 11 of infantry, and Queen Anne I of cavalry and 11 of infantry. Under the First and Second Georges the army was increased by 40 regiments, and a further number were added during the American and Peninsular Wars. An additional battalion was added to each of the first 25 regiments of foot in 1857-59, and the 100th R. was raised in Canada in 1858. Finally 3 regiments of cavalry (the 19th, 20th, and 21st Hussars) and 9 of infantry (101st to 109th) were formed from the European regiments in the service of the old East India Company. In the French and German armies 3 battalions, and in the Austrian army 6 (3 field, 2 reserve, and one dépôt) battalions go to every infantry R.

Regimental Schools are attached to each R., battalion, corps, or garrison in the British army, for the instruction of the non-commissioned officers and men and their children. The commanding officer may require married soldiers under pain of forfeiture of certain privileges to send their children to these schools, where a good sound education is given by the regimental schoolmasters. Soldiers, orphans of soldiers, and children of soldiers

serving abroad, are instructed free of charge, 1d. per head per month being charged for other children, or 5s. each for the children of officers. An infant and industrial school under a schoolmistress is also attached to every corps. In some large garrisons, schools solely for the children of officers have been established.

Regiomontanus, properly **Johann Müller** or **Mölltor**, was born at Königsberg in Franconia, June 6, 1436. He early showed a strong mathematical bias, and after studying at Leipzig, went to Vienna in 1451. In 1461, he accompanied Cardinal Bessarion to Italy, to learn the Greek language with the view of getting a thorough knowledge of writings of the Alexandrian school. Returning in 1464, he next spent seven years at the court of King Matthias Corvinus of Hungary, after which he removed to Nürnberg, where, aided by Bernard Walter, a wealthy citizen, he established an observatory and printing press. In 1475 he was called to Rome by Pope Sixtus V. to superintend a proposed reformation of the calendar. At the same time he was appointed Archbishop of Ratisbon; but he did not long enjoy this honour, dying on July 6 of the succeeding year. As a mathematician and astronomer R. was the greatest of his age. In his *Tabula Directionum Projectionumque* (1475) he tabulated the first tangents published in Europe. Prior to this he had issued his *Ephemerides ab Anno 1475 usque ad Annum 1506*, and his *Kalendarium Novum* for the three years 1475, 1494, and 1513. The latter was probably the earliest European almanac. His observations at Nürnberg, which were supplemented by those of Walter, and published in 1544 under the title *Observationes 30 Annorum a J. Regiomontano et B. Walthero*, were used by Lacaille in the construction of his solar tables. They gave ample evidence of the inaccuracies of the Alphonsine tables; but the contemplated correction of these by R. was never undertaken on account of his premature death. His other works, chiefly tables, were for the most part published after his death. See Montucla's *Histoire des Mathématiques*, and Gassendi's *Life of Muller*; also Ziegler's *R., ein Vorläufer des Columbus* (1874).

Register, (1.) The compass in whole or part of a voice or instrument. The human voice is usually said to have a lower and upper register, the chest notes forming the former, and the head or falsetto notes the latter. Such notes as do not strictly come under either of these categories are sometimes spoken of as in the middle register. (2.) A stop or range of pipes on the organ.

Register, Lord Clerk, is an officer of the law and of the state in Scotland. He has custody of the national records, and is Keeper of the Signet (see SIGNET). The tenure of the office is for life.

Registration of Births, Deaths, and Marriages. 31 and 32 Vict. c. 122 repeals former statutes and provides for the establishment of a general register office in London, and for the appointment of a Registrar-General of Births, Deaths, and Marriages in England (see BIRTHS, REGISTRY OF). In case of death, some one present during the last moments, or some inmate of the tenement in which the death has happened, must, within five days after the event, give notice to the registrar of the district, and the informant must within eight days, to the best of his or her belief, instruct the registrar on the following points—the day of death, the name and surname, sex, age, rank or trade, of the deceased, and cause of death. The person giving the information must write in the register his or her name, with such other note as circumstances require for identification. Unless this be done, the entry in the register cannot be taken as evidence. No fee can be lawfully taken from the person giving the information. The Act affixes penalties to undertakers or others performing funerals without the registrar's certificate of death; and to the registering of any false statement regarding births, deaths, and marriages, the false informer being held guilty of perjury. In Scotland, the Registration Acts are in some respects more stringent than the English, consequently they secure more trustworthy statistics, especially as regards births. Births in Scotland must be registered within twenty-one days, deaths within eight days, and marriages within three days. See MARRIAGE.

Registration of Deeds. There is no general registry of deeds in England. As a limited protection to purchasers and

mortgagers, statutes have been passed requiring abstracts of deeds and judgments affecting lands in Middlesex and Yorkshire to be registered, under penalty of being otherwise void against subsequent purchasers. But these statutes do not embrace copyhold property, nor leases exceeding a term of twenty-one years. Some deeds must be enrolled (see ENROLMENT) in Chancery; but this registry being partial, does not generally assist those who seek a full knowledge of encumbrances on property. 1 and 2 Vict. c. 110 provides that no judgment of the superior courts shall affect lands, unless a memorandum of it shall be registered, under the name of the person whose estate is affected by it, with the senior Master of the Common Pleas division. Without renewal of entry, these registered judgments are only valid for five years. Real estate is not affected by a judgment or decree unless delivered in execution, and the execution is registered. In Scotland there is an admirable system of R. of D. affecting *heritable*, i.e., *real*, estate. The registration may be in virtue of a clause in the deed, or under the Act of 1698. The custom of inserting the requisite clause had its origin in ecclesiastical influence inducing parties to deeds to place their effects under the authority of the Church courts. There is a head register office in Edinburgh, and there are also burgh registers. By inspecting the latter as to burgh property, and the former as to all other property, every burden affecting heritage in Scotland can be ascertained. As regards England, see MORTGAGE.

Registration of Title to Land. See LAND, TRANSFER OF, BY REGISTRATION OF TITLE.

Regium Donum (Lat. 'royal gift'), an annual parliamentary grant formerly given in augmentation of the stipends of Presbyterian ministers in Ireland. From 1672 to 1682 Charles II. paid annually £600 of 'secret service money' to Irish Presbyterian ministers, and on the 19th June 1690 William III. authorised the payment of £1200 to six such ministers. Anne renewed the grant, placing its disposal in the hands of the Lord-Lieutenant, but for some time before her death it was discontinued. The R. D. was in 1718 restored and augmented by £800 from the civil list of England, the latter sum being distributed by the Rev. Dr. Calamy of London and other trustees to those Presbyterians who were unwilling to sign the *Westminster* Confession. But the orthodox refusing to be thus overawed, the supplement was immediately withdrawn till the accession of George II., when it was renewed and its arrears paid up. In 1784 an addition of £1000 was granted—the Seceders also receiving £500—and again of £5000 in 1792, from which date the R. D. was extended equally to all the Presbyterian ministers of Ireland. An arrangement by Lord Castlereagh (1803) that the congregations should be divided into three classes, receiving £100, £75, and £50 each, respectively, raised the R. D. from £6329, 16s. 10d. to £14,970, 18s. 10d. Irish currency, besides the sums paid to the Southern Association and the Secession Synod. Six years after the R. D. was extended to the Seceders, who, however, were to receive not more than £70, £50, or £40 each. From 1838 an equal grant of £75 was paid to each minister of both bodies, and in 1840 it was regulated that no bounty should be paid unless £35 a year were raised by local effort. Under the Irish Church Act of 1871 the R. D. was finally withdrawn, and nearly all its recipients commuted their life interest, thus forming a general fund of over £580,000, which yields in interests and dividends about £29,000 a year. The Sustentation Fund then founded produces £26,000, and the sum raised from pew-rents amounts to more than £44,000. Thus the members of the Irish Assembly have altogether (1878) an income of about £100,000 a year.

Regius Professor, a title borne by five Cambridge and eight Oxford professors, all of whose chairs were founded by Henry VIII., with the exception at Oxford of that of Modern History (1724), of Pastoral Theology (1842), and of Ecclesiastical History (1842); and in Scotland by all professors appointed by the crown.

Regnault, Henri Victor, a French physicist and chemist, was born at Aix-la-Chapelle, July 21, 1810. After serving in a drapery business in Paris, he entered the École Polytechnique in 1830, and two years later began active duties in the department of mines. Subsequently he became professor at Lyon, and in 1840 was appointed to the chemistry chair in the École Polytechnique, which he gave up the next year for a similar chair in the Collège de France. He now turned his attention to experi-

mental physics, and made valuable researches into the properties of solids, liquids, and gases, determining their specific heats, compressibility, &c. In 1854 he became director of the porcelain manufacture at Sèvres, a branch of industry which engaged much of his subsequent time. On returning to his laboratory after the siege of Paris in 1871, he found that the results of over 600 observations of the thermal phenomena accompanying expansion of gases had been destroyed. He died after a long and painful illness, January 19, 1878. As an experimentalist he was among the foremost of his time, and the facts embodied in his numerous memoirs before the Academy of Sciences and in the *Annales de Chimie* and other scientific journals, are invaluable alike to the chemist and physicist. His chief work is *Cours Élémentaire de Chimie* (4 vols. 1847-49).

Regnier, Mathurin, the creator of classical satire in French literature, was born at Chartres, December 21, 1573. He was the nephew of the poet Philippe Desportes, under whose auspices he first cultivated poetry. In 1593, he accompanied Cardinal Joyeuse to Rome, returning after a stay of eight years, disappointed in his hopes of advancement—a result which was perhaps due to the irregularities of his life. He visited Rome once more in the train of Béthune, ambassador of Henri IV., and seems to have availed himself of his opportunities to make a careful study of Italian poetry. In 1609 he became canon of the church of Notre Dame in Chartres, and from this period he was able, without anxiety, to cultivate his poetical tastes, and to abandon himself 'à la bonne loi naturelle.' He enjoyed the friendship of some of the most distinguished men of his time, and was known among his friends as 'le bon R.' He died at Rouen, October 22, 1613. The works of R. comprise satires, epistles, elegies, epigrams, sonnets, and miscellaneous poems. On his satires, sixteen in number, his fame confessedly rests. They were highly estimated by Boileau, but many have found in this old Juvenal of France a power which he himself does not exhibit. They are unlike all other French poetry of the age of Henri IV., being vehement in tone, and somewhat rugged, reminding us of his English contemporaries, Hall and Donne. R. is an artist rather than a moralist, and concerns himself more with the painting than the lesson to be taught. His style is his best creation, and he has been aptly termed by Sainte-Beuve the Montaigne of French poetry. Editions of his works are numerous. The chief are those of Paris (1608), Leyden (1652), Amsterdam (1729), Paris (1780, 1808, 1819), the best are those by M. Viollet le Duc (Paris, 1822, reproduced 1853), and Barthélemy (Paris, 1862), and Lacour (1867). See Sainte-Beuve, *Tableau de la Poésie Française au Seizième Siècle*.

Reguardant, a heraldic epithet applied to an animal with its head turned backwards.

Regular Canons. Canons were a new class of priests that arose in the 8th c., intermediate between the regular and the secular clergy, that is, they adopted in part the mode of life of monks, but without taking vows, while they also performed ministerial functions in certain churches. In the 11th c., when various disorders had arisen among them, Pope Nicholas II. attempted to re-form them on the old constitution, while other associations were formed with a constitution more of the nature of a monkish rule. Hence arose at this time the distinction between R. C. and Secular Canons. See REGULAR CLERGY.

Regular Clergy was the name given to all those—monks, friars, &c.—who devoted themselves to a religious life under a monastic 'rule' (Lat. *regula*: see MONACHISM), as distinguished from the secular priests, who acted as ministers of religion to the people.

Regulations, Military and Na'vy, are in general all regulations issued by the War Office and Admiralty for the use of officers in the army and navy to ensure uniformity in matters of discipline, drill, finance, &c. They include the Mutiny Act, the Articles of War, the Queen's Regulations, the periodical warrants and orders, and the monthly circulars issued by the War Office and Admiralty to the two services.

Regulus ('little king') a name given by the alchemists to an intermediate product in the smelting or reduction of metallic ores, and which is still retained to indicate certain stages in the reduction of copper and of some other metals. The term does not indicate any precise compound or proportions.

Reg'ulus, a star of the first magnitude in the constellation Leo (q. v.), situated at the point of the well-marked 'sickle.'

Reg'ulus. See GOLDEN-CRESTED WREN.

Reg'ulus, Marcus Atilius, a celebrated Roman general, was consul with L. Julius Libo in 267 B.C. Having subdued the Salentini and taken Brundisium, he obtained a triumph, and was raised to the consulship a second time with L. Manlius Vulso Longus in 256 B.C., the ninth year of the first Punic War, which the Romans were now eager to end. Accordingly, the consuls were despatched to Africa with 330 ships. At Heraclea they met a more numerous Carthaginian fleet, under Hamilcar and Hanno, which they defeated. Landing in Africa, they took Clypea, and making it their headquarters, laid waste the Carthaginian territory. On the approach of winter the Roman senate imprudently withdrew one-half of their troops, leaving R. in command of the rest. Acting with true Roman vigour, he routed a large Carthaginian army with many elephants and cavalry under Hasdrubal, Bostar, and Hamilcar, killing 15,000 men, and capturing 5000 with 18 elephants. This victory enabled him to advance within 20 miles of the capital, so that the Carthaginians, harassed at the same time by a Numidian revolt, sued for peace. But the terms offered by R., now insolent with success, were so intolerable that they determined to hold out; and putting their forces under the command of Xanthippus, an able Macedonian general, who at this time arrived at Carthage with a force of Greek mercenaries, they totally defeated R., killing 30,000 men, and capturing the general himself. Only 2000 Romans escaped to Clypea (B.C. 255). After five years' captivity R. was sent to Rome with an embassy to treat for an exchange of prisoners, having sworn to return if the embassy was unsuccessful. On his subsequent conduct no embellishments of legend and poetry has been spared. He is said, as a Carthaginian slave, to have refused at first to set foot within his proud native city, or speak in the assembly of the venerable fathers. And when at last he did consent to advise them, it was strenuously to insist that neither peace nor an exchange of prisoners should be granted, 'donec labantes consilio patres firmaret auctor numquam alias dato.' Then heedless alike of the counsels of his friends and the tears of his wife and children, he returned to his African prison 'egregius exul.' There he is said to have been put to death by being placed in a chest full of iron nails, with his eyelids cut off, plunged first into a dark dungeon, and then exposed to the scorching rays of a burning sun. The story of his tortures is most likely one of those calumnious exaggerations so usual with the Roman writers in speaking of their enemies.

Re'i, the nominal unit of account in Portugal and Brazil, but no longer existing as a coin. A thousand reis=a Milrei (q. v.).

Reich'enbach, a town of Saxony, 11½ miles S.E. of Zwikau by rail. It has two churches and a realschule, and is the chief seat of an extensive woollen manufacture. Pop. (1875) 14,620.

Reich'enbach, a town of Prussian Silesia, on the Peilbach, at the base of the Eulengebirge, 39 miles S.E. of Liegnitz by rail. It has old fortifications, a castle, eleven churches, and a synagogue, and is the centre of a rich manufacturing district, embracing the great manufacturing villages of Langenbiefau and Peterswaldau. The town itself has six cotton factories, and carries on linen and woollen manufacture, yarn bleaching, dyeing, and printing. Pop. (1875) 7267. R. was the scene of a victory of Friedrich the Great over Laudon in 1762.

Reich'enbach, Karl, Baron von, a German naturalist and manufacturer, was born at Stuttgart, February 12, 1788. Educated at Tübingen University, R. for several years entertained the chimerical project of founding a new German state in the South Sea Isles. He thus incurred the suspicion of the police of Napoleon I., and for several months was confined in the fortress of Hohenasperg. On his release he devoted himself to the study of physical science, and its applications to industrial art. After visiting the chief factories of France and Germany, he established a blast furnace at Villengen, and large kilns at Hausach for charcoal-making. From 1821 onward, with the aid of Count Hugo zu Salm, he established at Blansko in Moravia several factories, which he managed with such skill and economy as to gain wealth enough to purchase large estates, among them the Château de Reisenberg. He died at Leipzig, January 19, 1869. Many of R.'s discoveries are most important. He inves-

tigated chiefly the compound products of the distillation of organic substances, and thus discovered several new compounds of carbon and hydrogen, such as creosote (1833) and paraffin. His works are *Das Kresot und seine Gebrauche* (Vienna, 1832). *Geologische Mittheilungen aus Mähren* (Vienna, 1834); *Physikalisch-physiologische Untersuchungen über die Dynamide des Magnetismus und der Electricität und ihre Beziehungen mit der Lebenskraft* (Brunswick, 1847-49), in which work and those that follow the author seeks to establish the existence of a new substance 'Od' (q. v.); *Odisch-magnetische Briefe* (Stuttg. 1852-56); *Der Sensitiv-Mensch und sein verhalten zum Od* (Stuttg. 1854); *Höhlenglaube und Afterswissenschaft*, in reply to Carl Vogt. (*ibid.* 1856).

Reich'enberg, the second town of Bohemia, and one of the most important manufacturing towns of Austria, is situated on the Neisse, 55 miles N.N.E. of Prague by rail. It has a castle and rathaus of the 16th c. Woollens and cottons form the staple manufactures, but dyeing is also carried on, while small-arms, hats, gloves, musical instruments, and gold and silver wares are produced. The total annual produce of the town amounts to £400,000. Pop. (1870) 22,394. In the Austro-Prussian war of 1866 R. was the headquarters of Prince Friedrich Karl.

Reich'enhall, a town in Upper Bohemia, on the left bank of the Saale or Saalach, 2 miles from the Austrian frontier, and 13 S.W. of Salzburg by rail. It is beautifully surrounded on three sides by an amphitheatre of mountains, the Untersberg, Lattenberg, Müllnerhorn, and Hoch-Staufen, and has been almost entirely rebuilt since the fire of 1834. It is a favourite watering-place, visited annually by 5000 persons, and owes its importance to its being the central point of the four great Bavarian saltworks, which are connected by conduits of an aggregate length of 45 miles, by means of which the surplus brine is carried from the Berchtesgaden mines to R., and thence to Traunstein and Rosenheim. The *Salinengebäude* are situated in the market-place, with the offices on the right, and four *Sudhäuser* ('boiling-houses') on the left. The sources of the salt springs, one of which, the *Edelquelle*, is impregnated to the amount of 24 per cent., are 14 in number, 50 feet deep, and are reached by a descent of 72 steps. The principal resorts of the visitors are the *Haupt-Brunnhaus* ('pump-house'), the *Curhaus Achselmannstein*, the *Gradrhaus*, and the *Gradrpark*, the latter with a salt-water fountain 40 feet in height. Pop. (1870) 3312.

Reich'stadt, Napoleon François Charles Joseph, Duc de, called Napoleon II. by the Bonapartists, was the son of Napoleon I. and Maria Louisa of Austria, and was born at Paris, March 20, 1811. Transported with joy at his birth, the father himself announced it to the congratulating throng with the words '*C'est un roi de Rome.*' Napoleon abdicated in his favour in 1814, but Louis XVIII. was called to the throne, and Maria Louisa with her child then retired to Schönbrunn, near Vienna. On the conclusion of the Treaty of Vienna, she removed to Parma, but her son still remained at the Austrian court with his grandfather Franz I., who educated him like a prince of the imperial family, and in 1818 made him Duc de R., with the rank of a prince of Austria, since by the Treaty of Vienna he was excluded from the inheritance of the Duchy of Parma. He was thought of as a candidate for the French throne in the Revolution of July 1830, but the project came to nothing. In fact, he had never been very vigorous either in body or mind, and when, after passing through all lower grades of military office, he had risen to be commander of a battalion, the speedy progress of laryngeal phthisis compelled his retirement to Schonbrunn, where he died, July 22, 1832. His last words were a piteous cry to his mother, '—Ich gehe unter, meine mutter, meine mutter!' See the works of Montbel (Par. 1833), Lecomte (1842), Guy (1856), and Saint-Felix (1856).

Reid, Captain Mayne, an English novelist, was born in Ulster in 1818. He proceeded to New Orleans in 1838, and after several years of adventurous travel in Mexico and the States, settled in Philadelphia. In 1845 he obtained a commission in the United States army. He served in the Mexican campaign, was present at the siege of Vera Cruz, and was wounded at Chapultepec. He raised an American detachment of volunteers in 1849 to assist the Hungarians in their memorable struggle with Austria,

and was on his way to the East when the insurrection collapsed. Shortly afterwards, taking up his residence in London, he assumed authorship as a profession. He has written many novels, in all of which there runs a dash of wild adventure. They include *The Rifle Rangers* (1849); *The Scalp Hunters* (1850); *The White Chief* (1855); *The Maroon* (1860); *The Headless Horseman* (1865); *The Child Wife* (1868); *The Death Shot* (1873), and the *Flag of Distress* (1876). His books for boys are immensely popular, and while gratifying the juvenile taste for excitement are also designed to popularise the study of geography and natural history. Captain R. started the short-lived monthly magazine *Onward* in 1869. A collected edition of his works in 15 vols. appeared in New York in 1868. A series has been published in England under the name of the *M. R. Library*, and his tales have been translated into most Continental languages.

Reid, Thomas, was born in the parish of Strachan, Kincardineshire, April 26, 1710. He entered Marischal College, Aberdeen, at the age of twelve, and there, as in after life, fulfilled the prediction of his schoolmaster, that he 'would turn out to be a man of good and well-wearing parts.' He took the degree of M.A. in 1726, studied thereafter for the Church, spent some time in London, Oxford, and Cambridge, and in 1732 was presented to the parish of New Machar, where he spent fifteen years. Here he devoted himself to intense study, in particular examining the facts of external perception. His first publication, an *Essay on Quantity*, was contributed to the Transactions of the Royal Society of London in 1745. In 1752 he obtained the chair of philosophy in King's College, Aberdeen. His course of instruction embraced mathematics and physics, as well as mental and Moral Philosophy. In 1764 appeared his *Inquiry into the Human Mind on the Principles of Common Sense*. This was the result of study directed towards a refutation of Hume's sceptical teaching in the *Essay on Human Nature*. Immediately on its appearance the author was called to Glasgow College to fill the chair of Moral Philosophy vacant by the resignation of Adam Smith. For twenty years he faithfully discharged the duties of this chair; but the only work he published in connection with it was a brief account of Aristotle's *Logic*, appended to Lord Kames's *Sketches of the History of Man*. In 1785 he published his *Essays on the Intellectual Powers of Man*, containing a theory of external perception, and of a common sense as the basis of knowledge and belief in general. The *Essays on the Active Powers*, which followed in 1788, traversed the field of ethics, and gave an analysis of the mechanical, animal, and rational principles of action, with a discussion of free-will. R.'s last literary work was a historical account of Glasgow University for the *Statistical Account of Scotland* (1794). Mathematics formed the study of his old age. He died at Glasgow, October 7, 1796. Hume's Philosophy of Scepticism was no sooner given to the world, than Kant in Germany and R. in Scotland set themselves to expose it. But while Kant soared into the region of intuitions and pure reason, R. contented himself principally with an examination of external perception, striving to overthrow Berkeley's idealism, from which Hume's scepticism sprang. Using the inductive method, he professed to discover the genuine or common reason of man, substituting this for the paraphernalia of ideas which he imagined had taken the place of truth in Berkeley's theory. His philosophy is a plea for perceived reality. He begins in experience, and asserts from experiment that we have in hearing, sight, &c., not only *sensations*, but also *perception* of external bodies causing these sensations. This is the testimony of man's common sense. Thus he seeks to establish a real material and moral world entirely independent of ourselves. But his induction is far from thorough; many of his first principles are reducible to simpler forms. No two words could have been more unfortunately chosen than those he uses most—*Common Sense* and *Instinct*. The ordinary meaning of these terms is almost the reverse of that which he would take from them. Few entirely unacquainted with his system would suppose that by these names he denominates the highest and most abstract powers of the mind. But whatever the results of R.'s philosophy, he founded a method which in the Scotch and French schools has contributed much to the development of mental science, especially of psychology. For accounts of the 'Common Sense School' of philosophy, consult Cousin's *Philosophie Ecossaise*, and McCosh's *Scottish Philosophy*. See the

great, but unfortunately incomplete, edition of R. by Sir William Hamilton (1846).

Reigate (from *Ridgegate*, the passage, that is, through the ridge of the North Downs), a market-town of England, in Surrey, 23 miles S.W. of London by rail, has a fine parish church (restored 1858) in Third Pointed style, containing the tomb of Lord Howard of Effingham, besides three district churches, a town-hall, public hall (1861), and grammar-school (founded in 1675). Under the scanty remains of a castle of the Earls of Warrenne is an excavation, known as the Barons' Cave. The parish includes the Redhill Reformatory (1849), with 248 boys in 1871, and the Earlswood Lunatic Asylum, with 510 patients. R. has no important industries, but carries on a considerable trade in agricultural produce. It publishes a weekly newspaper, and sent one member to Parliament up to 1867, when it was disfranchised for corrupt practices. Pop. (1851) 4927; (1871) 15,916.

Reign of Terror, the name applied to the period of the French Revolution between the fall of the Girondins (q. v.) in May 1793 and the revolution of Thermidor, July 1794. A triumvirate consisting of Robespierre, Couthon, and St. Just held the whole power in their hands, uniting in their persons the influence of the Jacobin Club, the power of the Convention, or rather of the dominant *Montagne*, and the authority of the *Comité de Salut Public*. They declared 'terror the order of the day,' and the guillotine was kept incessantly busy. The *Revolutionary Tribunal*, originally appointed at the suggestion of Danton in March 1793 under the name *Tribunal Extraordinaire*, having a Judge-President, a permanent jury, and for its Attorney-General or Public Prosecutor the bloodthirsty Fouquier-Tinville, condemned, without even the form of a trial, all who were brought before it, as aristocrats, *ci-devants*, reactionists, or federationists. On the 13th of July 1793, Marat was murdered by Charlotte Corday. The republican calendar was introduced on the 5th of October. On the 16th Marie Antoinette was guillotined, and on the 31st of the same month twenty-one of the leading Girondins met the same fate. Philippe Egalité, Duc d'Orleans, was executed on the 6th, and Madame Roland on the 8th of November. In the same month the Christian religion was declared a blasphemous superstition, and a Feast of Reason was held in Notre Dame, the Goddess of Reason being represented by a famous courtesan. In the beginning of 1794 the secondary Terrorists themselves began to fall before the relentless triumvirate. On the 24th of March, Hebert and Anacharsis Clootz, on the 5th of April Danton and Camille Desmoulins, were guillotined. In the same month fell the Princess Elizabeth, sister of Louis XVI., the chemist Lavoisier, and the philosopher Condorcet. On the 8th of June Robespierre restored a form of religion, and a great fête of the *Être Suprême* was arranged by David the painter, Robespierre himself being the principal actor. But his fall was at hand. On the 8th Thermidor (26th July) 1794 he spoke for the last time in the Convention, and on the 10th Thermidor he was guillotined along with Couthon, St. Just, and Henriot. Power fell into the hands of Tallien, Barras, and the *Thermidorians*, by whom the Directory was soon formed, and the R. of T. was over. In the provinces it had been no less sanguinary than in Paris. Couthon and Collot d'Herbois perpetrated shocking barbarities at Lyon; and at Nantes, Carrier, by means of wholesale massacres and his famous *Noyades*, or drownings in the Loire, is said to have put 32,000 persons to death. The number of those who fell by the guillotine in Paris is estimated at about 4000. In June and July 1794 no fewer than 1507 persons were executed.

Rei Interventus, a term of Roman law denoting the doing, or refraining from doing, some act, on the faith of a bargain or promise (see OFFER AND PROMISE); in consequence of which act the law holds that neither party can draw back. To give R. I. this effect, it must flow from the contract or promise, and must be known to the party against whom it is pleaded.

Reimar'us, Hermann Samuel, a German philosopher, born at Hamburg, December 22, 1694, studied theology and philosophy at Jena, and was a *privat docent* at Wittenberg from 1716 to 1723, with the exception of a two years' tour in Holland and England. He was appointed rector at Wismar in 1723, and in 1728 was called to the chair of Hebrew in the Hamburg

Gymnasium, which he held till his death, March 1, 1765. Besides a scholarly edition of Dion Cassius (1750), R. published *Die vornehmsten Wahrheiten der natürlichen Religion* (1754), *Vernunftlehre* (1756), *Betrachtungen über die Kunsttriebe der Thiere* (1762), works that ran through many editions in their day, but are now less remembered than his assault on supernatural religion, first given to the world by Lessing (q. v.), under the title *Wolfenbüttelsche Fragmente eines Ungenannten* (1777-78). See J. G. Büsch, *Memoria Reimari* (Hamb. 1769).

Rein'deer (*Tarandus rangifer*), a species of Deer (q. v.) inhabiting the northern and Arctic regions of the world, and distinguished from other species of deer by the circumstance that both sexes possess horns. The R. appears to be represented by two varieties: the R. proper being found in the N. of Europe and Asia, whilst the Caribou represents the American variety. There are no grounds for referring these animals to different species, the minor difference of size being insufficient to constitute a specific distinction. The R. of Europe varies greatly in size. A large R. equals a stag; while the full-grown Caribou attains a height of about 3 feet 6 inches at the shoulder. The colour varies according to the season. The summer tint is a sooty brown, the under parts being grey. These hues grow lighter in winter, the grey tints becoming white. The R. constitutes the wealth of the Laplander. It feeds on the lichens which it disinters from the snow in winter. It is a hardy creature, and does not appear in some cases to be over well cared for. The average weight a R. will carry with ease is about 200 lbs., and its pace averages 9 or 10 miles an hour. The senses of the R. are acute. In a wild state the animal migrates, leaving the forests in summer for the open hill-country. It is singularly liable to the attack of flies and other insects which deposit their eggs in its hide, and cause painful sores through the development of the larvæ in the skin. The Caribou is hunted in America for the sake of its flesh, and especially for the layer of fat, known as *depoûillé*, and which is obtained from the back and croup of the male animal. The valued *Pemmican* (q. v.) is made from its flesh. The Caribou is found in herds of large size, and the skin is highly valued for making 'hunting-blankets.'

Rein'deer Moss, or *Cladonia rangiferina*, is perhaps, economically regarded, the most important of all the northern lichens. It frequently overspreads large tracts of sterile country in northern and arctic Europe and America, constituting sometimes the sole terrestrial vegetation. As such it is the main support in Lapland and Esquimo-land of the reindeer—one of the chief articles of food of the inhabitants. In some parts of Norway this lichen is also regularly used as a winter fodder for cattle. About the end of September it is scraped into heaps by means of large iron rakes, and the position of these heaps is marked by poles sufficiently tall to be visible above the winter snows. In the same country it is commonly used as a stuffing material in the construction of the usual log houses, and is also used for stuffing pillows by the Lapps. Occasionally, too, it forms at least an ingredient in the food of man (*Lindsay*). *Cladonia* is a large genus of the Lecideaceous division of the lichens, and is characterised by its coloured globose or button-shaped fruit growing at the tips of vertical hollow shrub-like or cup-shaped processes, arising from a foliaceous or crust-like thallus.

Reinette (Fr. 'little queen'), sometimes, but improperly, **Rennett**, is a name given to a group of apples in the same manner that the names 'pippin,' 'nonpareil,' and 'ru-set,' are applied to other groups. R. do not appear to have any one particular and special character to distinguish them. In England they are not so much grown as in France, Germany, &c.; yet still in most choice selections we find some kinds of R. among both the early and late dessert fruit. At a congress of German pomologists (see *POME*) held in 1876, out of fifty varieties of apple selected by them as best adapted for general cultivation in that country, the large proportion of fifteen are classified under R., including *Champagne R.*, a good kitchen sort; *Carmelite R.*, one of the best for table and kitchen; *Normandy R.*, a good hardy variety, with rich aromatic flavour; and *Canadian R.*, a fine dessert fruit, and excellent for cooking.

Reinforce, in artillery, an additional thickness of metal applied about the breech of a gun to strengthen it; also the part strengthened. In smooth-bore ordnance the portion between

the base ring and the ring near the trunnions is made up of the first and second reinforces, the former being nearest the breech where the metal is thickest.

Rein'kens, Hubert Joseph, the first of the 'Old Catholic' bishops; was born at Burtscheid, near Aachen, 1st March 1821. After working for three years in a spinning-mill, he entered the university of Bonn (1844), was ordained priest (1848), and held the chair of ecclesiastical history at Breslau (1857-74). A pamphlet published on the occasion of the jubilee of his university (1861) had brought him into conflict with his superiors, and shortly after the promulgation of the Infallibility Dogma (1870) he appeared as a leader of the *soi-disant* 'Old Catholics' (q. v.). His deposition from the professorship by Bishop Förster (1871) remained unrecognised by the Prussian government, but was followed up by excommunication. Thrust out from one Church, R. proceeded with the formation of another, of which he was consecrated bishop, August 11, 1873. As such he has been recognised by Prussia, Baden, and Hessen, though not by Bavaria, and as such he has addressed a pastoral to the 'Old Catholic Church' in Germany (1875). He is author of *De Clemente Presbytero Alexandrino* (1851), *Hilarius von Poitiers* (1864), *Marin von Tours* (1866), *Aristoteles über Kunst besonders über Tragödie* (1870), *Ueber Päpstliche Unfehlbarkeit* (1871), *Luise Hensel und ihre Lieder* (1877), &c. See *The New Reformation, a Narrative of the Old Catholic Movement* (Lond. 1875).

Reis Effen'di, the title of the chief of the Turkish diplomatic bureau. His functions are those of Minister of Foreign Affairs, and Chancellor of the Empire, in the latter of which capacities he acts as a sort of Minister of the Interior under the direction of the Grand Vizier.

Rejoin'der, in English law, means the defendant's answer in an action to the plaintiff's *Replication*.

Relap'sing Fe'ver, Fam'ine Fe'ver, Mil'iary Fe'ver, or Ty'phus Recurr'ens, as it is sometimes called, is a contagious specific fever, depending upon the absorption of a poison into the blood. It is called *famine fever*, as it prevails especially in times of scarcity and famine. Dr. Murchison describes the symptoms as follows:—A very abrupt invasion, marked by rigors or chilliness; quick, full, and often bounding pulse; white moist tongue, rarely becoming dry and brownish; tenderness at the epigastrium; vomiting, and often jaundice; enlarged liver and spleen; constipation; skin very hot and dry; no characteristic eruption; high-coloured urine; severe headache, and pains in the back and limbs; restlessness and occasionally acute delirium; an abrupt cessation of all these symptoms, with free perspiration, about the fifth or seventh day; after a complete apyretic interval (during which the patient may get up and walk about), an abrupt relapse on or about the fourteenth day from the first commencement, running a similar course to the first attack, and terminating on or about the third day of the relapse; sometimes a second or even a third relapse; mortality small, but occasionally a death from sudden syncope, or from suppression of urine and coma; after death, no specific lesion, but usually enlargement of liver and spleen.

It has been conjectured that the 'sweating sickness' of the 15th c. was a variety of R. F.; but the first reliable record of it is in the autumn of 1739, when it was epidemic in Dublin; and it prevailed in Ireland, more or less, until the great epidemic of 1817-19, which commenced in Ireland and spread to Britain. Previous to the outbreak, there had been great destitution in Ireland, through the failure of crops. It was estimated that an eighth part of the population was affected, and the total number of deaths was estimated at 44,000. England and Scotland also suffered, but not to the same extent. Since then it has reappeared in 1826, 1842-43, 1847, 1851, 1853, 1865 (on the Continent), 1869, and 1870.

R. F. is contagious, and the cutaneous excretion contains the poison, which, being thrown off by the skin, infects the air, the clothes, and perhaps the walls of the room. Dr. Obermeier of Berlin has discovered that in persons suffering from R. F. there are fine filaments, supposed to be bacteria, in the blood, that have undulatory movements and spiral contractions. They are only found in the paroxysms of the fever, and are absent during the intermissions.

Relative Keys, in music, keys whose first, third, and fifth degrees form a common chord made up of notes of the key to which they are related. Taking a major key, the keys nearly related to it are its dominant or fifth above, its subdominant or fifth below, its relative minor key (see MUSIC) which bears the same signature and the dominant and subdominant of that minor key. The R. K. of C Major are thus G Major, F Major, A minor, E Minor, and D Minor.

Relative Rank. Officers in the British navy rank with officers in the army according to the following table:—

Rank in Navy.	Rank with	Rank in Army.
1. Admirals of the Fleet		Field-Marshal
2. Admirals		Generals
3. Vice-Admirals		Lieutenant-Generals
4. Rear-Admirals		Major-Generals
5. Captains of the Fleet		Brigadier-Generals
6. Commodores		Colonels
7. Captains of 3 years' standing		Lieutenant-Colonels
8. Captains of less than 3 years' standing		" "
9. Commanders	rank next to	" "
10. Lieutenants of 8 years' standing	rank with	Majors
11. " of less than 8 years' standing		Captain
12. Sub-Lieutenants		Lieutenants
13. Mid-shipsmen		Sub-Lieutenants.

Non-combatant officers have R. R. similar to that enjoyed by certain combatant officers. Thus a quartermaster in the army has in virtue of his position the R. R. of lieutenant, and a paymaster the R. R. of captain.

Release, in the law of England, is a discharge of an interest in land, or of a legal right.

Rel'evancy, in the law of Scotland, means that a plea is well founded as regards law, if it can be proved as matter of fact.

Rel'ics (Lat. *reliquie*, 'remains') are the bones, clothes, or other articles belonging to those who were revered in their lifetime, which are preserved as memorials of them after their death. It was a common practice among the Greeks to pay divine honours to great public benefactors and heroes after their death; and their bones were believed to afford protection to a city or country. With this view their R. were sometimes transported from a distant place of internment, as when the bones of Theseus were brought from the island of Scyrus to Athens.

The heathen converts to Christianity very naturally transferred to Martyrs (q. v.) the honours they had been accustomed to pay to their heroes. Altars and shrines were built over their graves. Their R. were carried to every country in Christendom, and chapels or oratories built to contain them; the most precious of all being the wood of the cross of Christ, which was discovered by the Empress Helena on her visit to Jerusalem (about 325). Numerous miracles were wrought by these R., such as the cure of all kinds of diseases. They were especially efficacious for protection against demons. The Christian Father found a notable precedent for these miracles in the case of Elisha (2 Kings xiii. 20, 21). St. Augustine (*De Civ. Dei*) affirmed that in his own diocese of Hippo seventy miracles had been wrought by the body of St. Stephen, and in a neighbouring region, where it had been before, a far greater number, including five cases of the dead being raised to life again. In the 5th c. the reverence paid to saints came more and more to consist in the superstitious worship of R. Men of peculiar sanctity claimed the power of discovering the graves of the martyrs by prayer and fasting. The place was often revealed by a vision, and angels did not disdain to transport the R. through the air. As the tomb of a martyr had in early times been regarded as the best place for celebrating the Eucharist, it became common to place R. beneath the altar in churches; and a decree of the second Council of Nice (787) forbade the consecration of a church without R. At a later period, during the Middle Ages, the worship of saints almost swallowed up the worship of God. Great numbers of old saints were discovered and new ones made. Loads of R., often articles of a ridiculous description, were brought from the East by pilgrims. The Greeks and Syrians, from whom they were procured, soon became adepts at manufacturing them for sale to Europeans. In Europe the monks and inferior clergy carried them about through the provinces and sold them, or allowed the people to see, handle, and kiss them, on paying for the privilege.

The worship of R. was one of the abuses discarded by the Protestants at the Reformation. In the Church of Rome there are various opinions as to the kind or degree of worship that

ought to be paid to R., but the veneration with which they are regarded generally was defended by Bellarmine (*De Eccl. Triumphantis*) by the following arguments:—1. Scripture examples: (1) The Israelites carried the bones of Joseph with them from Egypt (Ex. xiii. 19); (2) the honour paid to the remains of Moses, who was buried by God himself (Deut. xxxv. 6); (3) the case of Elisha (2 Kings xiii. 20, 21); (4) the prophecy of Isaiah (xi. 10 *Vulg.*), that the sepulchre of the Messiah would be glorious; (5) the cure of a woman by touching Christ's garment (Mark v. 25-33); and (6) of the sick by articles which had touched Paul (Acts xix. 11, 12). 2. The decisions of councils. 3. The testimony of the Fathers. 4. Miracles wrought by R. 5. Miraculous discoveries of R. 6. The translation of R. from one place to another. See Gieseler's *Lehrbuch der Kirchengeschichte* (Eng. trans. Edin. 1855); Mabillon's *Acta Sanctorum*; Muratori, *Antiq. Itali. Medii Ævi*.

Relief, Parish. See POOR-LAWS, and PAROCHIAL BOARD.

Rel'igion, as a name, is used in ordinary language in at least three different senses:—(1) as the object of belief; (2) as the power of belief; and (3) as the manifestation of belief. Subjectively it expresses a state of mind, but of what that state of mind consists there have been as many explanations as there have been writers on the subject. Some Christians will not admit that there is any true R. but the Christian; all others are merely superstitions. But granting that they are false religions, there must be some point of agreement between them and the true R., otherwise they could not be compared. The question is, what is the essence of R., or the mental faculty which lies at the root of all its forms, true or false? The answer to this question, or the definition of R. given by some of the greatest thinkers may here be given. Plato—a likeness to God according to our ability; Schleiermacher—the feeling of absolute dependence; Feuerbach—covetousness, or wishing manifesting itself in prayer, sacrifice, and faith; Bretschneider—faith in the reality of God, with a state of mind and mode of life in accordance with that faith; Fischer—recognition of the mutual relation between God and the world; Theile—the recognition of a superhuman causality in the human soul and life; Jacobi—faith founded on feeling in the reality of the ideal; Kant—the observance of the moral law as a divine institution; Fichte—faith in the moral order of the universe; Hegel—morality become conscious of the free universality of its concrete essence; Schelling—the union of the finite with the infinite, or God's coming to self-consciousness in the world; Comte—the worship of humanity; Parker—voluntary obedience to the law of God; M. Müller—a mental faculty which, independent of, nay, in spite of, sense and reason, enables man to apprehend the infinite under different names and under varying disguises.

This religious faculty, whatever its exact nature may be, is at any rate analogous to our other intellectual faculties, and hence assumes different phases of development as mankind advances from a state of barbarism through all the stages of civilisation. It changes continually as man's knowledge of nature increases, for it originated in the natural tendency of the human mind to explain the surrounding phenomena of nature; and hence at different stages, or among people amid different surroundings and differently educated, it assumes the forms of Fetichism (q. v.), Dualism (q. v.), Polytheism (q. v.), Monotheism (q. v.), Pantheism (q. v.).

Again, R. may be regarded as developed in different creeds, each with so many adherents. Viewed in this light, its history will be found under the heads of HINDUISM, BUDDHISM, JEWS, CHRISTIANITY, MOHAMMEDANISM, &c. The following table (taken from a manual on Buddhism published by the 'Society for the Propagation of Christian Knowledge') gives the relative numbers of the adherents of the different religions, and the percentage of the population of the globe:—

Buddhists,	500,000,000	about 40 per cent.
Christians—Roman Catholics,	152,000,000	" 12 "
" Greek Church,	75,000,000	" 6 "
" Other Christians,	100,000,000	" 8 "
Hindus,	160,000,000	" 13 "
Mohammedans,	155,000,000	" 12 1/2 "
Jews,	7,000,000	" 1 "
Sikhs,	1,200,000	" .. "
Parsees,	150,000	" .. "
Other religions,	100,000,000	" 8 "
Total,	1,250,350,000	

See Nitzsch, in *Studien und Kritiken* (1828); De Wette, *Ueber Religion und Theologie*; Theod. Parker's *Discourse of R.*; Tiele's *Hist. of R.* (Eng. trans. Lond. 1878); M. Müller's *Lectures on the Origin and Growth of R.* (1878).

Offences against R.—The laws in the United Kingdom against apostasy, heresy, reviling the Church ordinances, and against the Jesuits and religious societies, are now obsolete.

Religious Tract Society, London, was founded, 1799, for 'the circulation of small religious books and tracts in foreign countries, as well as through the British dominions.' The nature of the religion taught in these publications is Evangelical Calvinism. Although the R. T. S. is nominally a tract society, by its constitution it also includes books among its publications. Again, its books have not been confined to strictly religious subjects, on the principle that almost all secular subjects may be treated in a religious manner. The circulation of the society's publications, which extends over the whole known world, is effected by means of depots, of grants to foreign societies and to missionaries, of libraries granted gratis or at reduced rates to parishes, schools, hospitals, &c., and of colportage, and through the book-selling trade. The funds of the society are divided into missionary and trade funds; the former, raised from subscriptions, donations, collections, and other free contributions, being all devoted to the grants of the society; the latter supporting all the expenses of publication and distribution. According to the seventy-ninth annual Report of the R. T. S., dated March 31, 1878, the number of publications issued in seventy-nine years was about 14,432; the total circulation in the same time, about 1,783,000,000; the total annual circulation about 63,000,000; and the number of languages and dialects in which publications have been issued 124. The Religious Tract and Book Society of Scotland claims to be the oldest of the kind in Great Britain. In 1875 the sale of its books amounted to 200,000, while its monthly and weekly periodicals had a circulation of about 1,810,000.

Reliquary is a relic-holder, the use of which arose in the early times of Christianity, when Relics (q. v.) began to be carried about the person as amulets. They were mostly small caskets, ornamented with the emblems of Christ or Biblical illustrations; sometimes they were cross-shaped. The constantly increasing veneration for relics led to the manufacture of reliquaries of the most varied forms and sizes, for which the most costly materials were employed, and in the decoration of which the highest efforts of the art of the different periods were displayed. See Lübke's *Ecl. Art in Germany* (Eng. trans. 4th ed.; Edinb. T. C. Jack, 1877).

Relocation, Tacit, a term of Scotch law, denoting a renewal of a lease, legally inferred from neither landlord nor tenant having given notice of intention to end it at the period stipulated for. Unless notice be given forty days before Whitsunday, there is T.R., the renewal being presumed to be for one year. See, in English law, HOLDING OVER, LANDLORD AND TENANT, NOTICE TO QUIT.

Remainder is an interest in an estate, to come into effect on the determination of another interest, or on the occurrence of some event. A R. is either *vested* or *contingent*. The former depends on an event which must happen; the latter on an event which may, or may not, happen. An interest to emerge on the death of some one is a vested R. An interest to emerge on the birth of some one is a contingent R. The analogous term of Scotch law is Fee and Liferent (q. v.).

• **Rembrandt van Ryn**, or **Harmenszoon**, the head of the Dutch school of painting, was born in Leyden, 15th July 1607. The story of his life is shrouded in a mystery which harmonises significantly with the chiaroscuro of his art, and both life and art are the outcome of a critical period in the history of a great people. All biographies prior to the first half of the 19th c. are vitiated by the fables of Houbracken and Weyerman, but many of the old errors have been dispelled by modern research. R.'s father, Harmen Gerritszoon, or Van R., was a well-to-do miller, and his mother, Neeltje, the daughter of a Leyden baker. As now appears, R. was born in his father's town house, but his birthplace was long supposed to have been a windmill on the Rhine above Leyden, and the fallacy mainly arose from the title of one of his etchings, 'The Mill of R.', though the title was only given in the 18th c. After

spending nearly three years in Swanenburg's studio in Leyden, he passed to Amsterdam, where he studied under Lastman for six months. In 1622 or 1623 he returned to Leyden, only to remove finally to the great city by the Zuyder Zee seven years later, in the bright dawn of his fame. Here the silvery tone and equal light of his earlier style rapidly gave way both in painting and etching to a novel, startling method, mysterious and sombre, in chiaroscuro strongly pronounced yet subtly toned, with vivid high-lights flashing forth from backgrounds of profoundest shadow. Besides many fine portraits, the more notable of his early works are 'The School of Anatomy,' 'The Elevation of the Cross,' 'The Descent from the Cross,' 'The Entombment' and 'Resurrection,' and above all, 'The Night Watch.' The period in which these were produced was the happiest in R.'s life. In 1634 he married Saskia, daughter of the juriconsult Ulenburgh, who brought him wealth, and whose fair face formed a constant theme for his pencil. Generous and hospitable, he formed a wide circle of friends, and stored his house with costly *bric-à-brac* and rare works of art. Everything went well till the death of Saskia in 1642. This blow was followed by a reaction against his art, and by a series of troubles, domestic and pecuniary. R. married again (probably twice), but the name even of the second wife is not certainly known. It is certain from documents still existing that in 1656 he was publicly declared bankrupt, and various causes are assigned for the disaster. But little is known of his declining years, except that he maintained his household in comfort and independence. He died 8th October 1668. Like nearly all the artists of Holland who preceded or immediately followed him, R. takes hardly any cognisance of the stirring political and religious events which give historical importance to his time. Even his portraits are not those of warriors or patriots but of peaceful burghers—the advocate, the burgomaster, the printseller, the writing-master. His landscapes show broad populous plains under cloudy sky or lurid sunset, weird windmills rising by the ponderous sea-dyke, or the sleepy hamlet in the polders girt with dark groves and silvery water-ways. In dealing with classical and Scriptural subjects, he rejected the Italian style, and going direct to nature, has incurred the wrath of critics like Pels, Fuseli, and Ronchaud by his choice of boors and *bourgeois* as types of beauty. The chief of his later large works are 'The Woman taken in Adultery,' 'The Peace of the Land,' 'The Bather,' 'The Preaching of John the Baptist,' 'The Adoration of the Magi,' 'Moses Breaking the Tables of the Law,' 'Jacob Wrestling with the Angels,' and 'The Syndics of the Guild of Clothmakers.' Quiet wonders how his magic colouring could have been produced under 'the leaden sky' of the Low Countries, and Vosmaer answers with a proud defence of his native land. But colour is always subordinate to chiaroscuro, the exquisitely subtle interplay of tints and shadows, delightful in harmony and delicate balancing. Each work is a masterpiece of soft, vapoury shading, a perfect tissue woven of golden light and thickest gloom, shone across by phantasmagoric gleams of intensest brilliancy. R. has been called 'the prince of etchers,' and among his great etchings are 'Ecce Homo,' 'The Death of the Virgin,' and 'Christ Healing the Sick,' also called the 'Hundred Guilder Piece.' A copy of the 'Hundred Guilder Piece' was bought in 1867 by Mr. Dutuit for £1180. The literature relating to the life and works of R., 'La Pléiade Rembrandtesque,' approaches the magnitude of a library. We can only refer to Smith's *Catalogue Raisonné* (vol. vii.); Blanc's *Œuvre Complet de R.* (1853-64); Hamerton's *Etching and Etchers* (1868); Vosmaer's *R., ses Précurseurs*, &c. (1853), and *R., sa Vie et ses Œuvres* (2d ed. 1877); Seymour Haden's preface to the catalogue of R.'s etchings exhibited at the Burlington Fine Arts Club (1877); and the forthcoming Life by Rev. C. H. Middleton.

Remigius, St., the apostle of Gaul, was born in 437, at Cerny in Laonnais, and raised in his twenty-second year to the archbishopric of Rheims. His labours were sealed by the baptism of Hlodwig in 496, and ere his death in 533 he saw almost the whole of his vast diocese converted to Christianity.—Another **St. R.**, Archbishop of Lyon from 852, opposed Hincmar (q. v.) in the strife engendered by the monk Goltschalk, and prevailed on the Synod of Valence (855) to recognise as orthodox the teaching of a twofold predestination. He died October 28, 875.

Remiremont, a town of the German empire, province of Lothringen, on the left bank of the Moselle, 16 miles by rail

S.E. of Epinal. It manufactures lace, linen, muslin, woollen fabrics, leather, and wrought iron. There is active trade, too, in corn, hemp, cattle, and cheese. R. is a very pleasant little town, with broad streets and fine walks. The parish church contains a very ancient crypt. The town owes its origin to a monastery founded at the beginning of the 7th c. Pop. (1875) 5668.

Remis'sio Injuris, a term of Scotch law equivalent to *Condonation* (q. v.).

Remittent Fever is one of the three varieties of malarious fevers, the other two being ague and malarious yellow fever. R. F. is supposed to depend upon the absorption of some organic poison into the blood, and is endemic in low-lying tropical districts. In its milder forms it is almost identical with severe intermittent fever; but in more severe cases it may merge into yellow fever. The different localities in which it has prevailed have caused it to be designated by various names, such as Walcheren fever, Bengal fever, bilious remittent of the W. Indies, jungle or hill fever of the E. Indies, African fever, Mediterranean fever, &c.

The symptoms of R. F. closely resemble those of intermittent fever, except in point of severity, but it is distinguished from it by the fact that in the interval there is no entire cessation of the fever, but simply an abatement or diminution. The disease generally continues from twelve or fourteen days, and the period of remission varies from six to twelve or fourteen hours. The fever is generally ushered in with gastric symptoms, uneasiness, depression, languor, nausea, and frequently very severe headache. The cold stage varies in intensity and duration, but in general there are shiverings and cold clammy perspiration, followed by a severe hot stage, with burning skin, more especially about the neck and forehead, intense headache, sleeplessness, nausea and vomiting, and frequently delirium. This stage, the duration of which is somewhat indefinite, ranging from six to twenty-four hours, is succeeded by a stage of sweating or subsidence, and may be followed by another attack similar to the first but more severe, the attacks and varying remissions constituting the fever. The liver, and more especially the spleen, are frequently much enlarged and tender on pressure. Jaundice is occasionally present, and hence the term bilious remittent. In very severe cases the tongue is brown and dry, sometimes quite hard, bilious vomiting is incessant, the neck is burning hot, delirium is present, there is intense thirst, and, almost invariably, obstinate constipation.

In the treatment of R. F. the first object to be attained is the relief of the bowels. This is sometimes extremely difficult, as nothing will remain for any length of time on the stomach. An enema will not answer the purpose, and it may be necessary to administer two or three drops of croton oil on the tongue. When the stomach can retain the medicine, a full dose of the compound powder of jalap should be given, or the compound colocynth pill, with two or three grains of calomel, and one quarter of a grain of the resin of podophyllin. When the bowels have been freely moved, quinine should be given in full and oft-repeated doses from five to twenty grains every three hours during the remissions. The quinine may be continued so long as the bowels remain free, and entire chinchonism is produced. Sponging the body with cold water, or with vinegar and water, often affords great relief, and accelerates the sweating stage. No relief is experienced until the patient breaks out in a copious perspiration, and this invariably affords relief. A severe attack of R. F. is very dangerous as regards life, and it is frequently necessary for Europeans to seek a change of climate before recovery takes place, and if this be not done there is usually a lengthened period of convalescence. In tropical, malarious districts the natives suffer almost as severely from R. F. as Europeans do. The only known specific in R. F. is quinine, following the exhibition of active cathartics.

Remonstrants. See ARMINIUS.

Re'mora, or **Sucking Fish** (*Echeneis Remora*), a teleostean fish, reaching a length of from 8 to 12 inches, and having on the top of its head a curious sucker, by means of which it can attach itself firmly to any object. It occurs in the Mediterranean Sea, and also in the Atlantic Ocean, and has been occasionally found on the coasts of Britain. The colour is a dark brown, the hue of the back being darker than that of the under parts. The R. is employed by the Chinese and by other nations in the capture

of turtles. The fish, secured by a ring—passed through the tail-fin—and line, is allowed to swim in search of turtles, which are met with sleeping on the surface of the water. The R. attaches itself by means of its sucker to the turtle, and is then drawn in by the line along with its prey. An allied species is the *E. scutata*, in which the sucker is very large. There is a single dorsal fin, and the ventrals are placed on the throat below the pectoral fins.

Removal of Goods by the tenant of a house is a violation of the landlord's right of *Lien* (q. v.), in Scotch law, *Hypothec* (q. v.). If rent be due at the date of removal, the landlord may follow the goods and seize them in payment within thirty days from the date of removal. But if the rent be not due when the goods are taken away, the landlord cannot do this.

Removal of the Poor. No pauper can be legally removed from any parish or workhouse till twenty-one days after notice of his being chargeable has been sent to the parish to which the order of removal is directed, with a copy of the examination and order, unless the order be submitted to, when the pauper may be moved directly. No removal can be made pending an appeal. Notice of appeal must be given fourteen days before first day of Sessions. The parish losing the appeal pays costs. Under 28 and 29 Vict. c. 79 no pauper can be removed from a parish after he has resided in it for one year, and residence in any part of a union has the same effect as residence in a parish.

Removing of Tenants is a term of Scotch law, denoting the giving up possession of a subject by a tenant on expiry of his lease. Notwithstanding expiry, the tenant may continue in possession, on a tacit understanding, from year to year. To authorise judicial removing, the tenant, when the lease does not provide otherwise, must be warned by the landlord to remove. The notice must be given forty days before the term of Whitsunday (15th May), on which the removal is to take place. In English law, see NOTICE TO QUIT.

Remscheid, a town of Rhemish Prussia, in the fine valley of the Lennep, 18 miles E.S.E. of Düsseldorf by rail. It has important manufactures of excellent woollen cloths, cutlery, iron wares, &c. As early as 1580 it had iron-foundries, producing hand-wrought bars. Pop. (1875) 26,120.

Rémusat, Charles François Marie, Comte de, born at Paris, March 14, 1797, after studying at the Lycée Napoléon, was admitted advocate, and in 1820 published a brochure, *De la Procédure par Juries en Matière Criminelle*, which achieved a marked success. Turning from legal studies, he attached himself for ten years to the press, writing for the *Tablettes Universelles*, *Globe*, and *Courrier Français*, and signing with his brother journalists the protest against the 'July Ordinances' (1830). Under the Citizen King's régime R. sat in the French Chamber as *Doctrinaire* member for Toulouse, served as under-secretary of state in the Ministry of the Interior (1836), and himself held the portfolio of that department from March to October 1840. The fall of Thiers brought him over to the Opposition, but for the next seven years he chiefly occupied himself in writing the brilliant philosophical treatises, *Essais de Philosophie* (2 vols. 1842), *Abélard* (2 vols. 1845), and *De la Philosophie Allemande* (1845), works which procured his election to the Académie des Sciences Morales et Politiques and the Académie Française (1846). After the 'February Revolution' (1848) politics again engrossed him; the department of Haute-Garonne elected him to the Constituent and Legislative Assemblies; and it was only after the *coup-d'état* and a seven months' banishment from France that he returned to private life and to his books (1852). England engrossed R.'s interest about this time, and his *St. Anselme de Cantorbéry* (1854) was followed by *Angleterre au XVIIIe. Siècle* (1856; 2d ed. 1865), *Bacon, sa Vie, son Temps, sa Philosophie* (1858), *Channing, sa Vie et ses Œuvres* (1861), *Philosophie Religieuse, ou De la Théologie Naturelle en France et en Angleterre au XVIIIe. Siècle* (2 vols. 1865), and *Histoire de la Philosophie en Angleterre depuis Bacon jusqu'à Locke* (1874). The events of 1870-71 caused him at length to resume the career of politics, and as Minister of Foreign Affairs he stood by Thiers down to the fall of the Conservative Republic in 1873. He died at Paris 6th June 1875. From Royer-Collard R. received the title 'Prince of Amateurs,' a *mot* whose seeming praise conceals a sting. Indeed, as politician, historian, and philosopher he enjoyed a reputation in his day which time will hardly justify; his writings, if we except perhaps the *Bacon*

and *Channing*, being rather remarkable for keenness and vivacity than depth or originality of thought. An additional instance of his *esprit universitaire* is furnished by *Abdard, Drame Philosophique* (1877) and *La Saint Barthélemy, Drame Historique* (1878), composed by R. during the years 1836-38, and now given to the world by his son, M. Paul de R. Overburdened with erudition, and utterly unsuited for the stage, these plays have yet an interest of their own as subtle psychological analyses and vivid delineations of two eventful epochs. See an article by P. Davergier de Hauranne in the *Revue des Deux Mondes* for November 1875.

Rémusat, Jean-Pierre-Abel, born at Paris, September 5, 1788, the son of a surgeon, was himself destined for the profession of medicine, but under De Sacy's influence conceived the notion of devoting all his energies to a study of Chinese. Without a dictionary, he compiled one for himself, and by 1811 produced an *Essai sur la Langue et la Littérature Chinoises*; whilst his natural bent asserted itself even in his M.D. thesis, *De Signis Morborum que e lingua sumuntur, præsertim apud Sinenses* (1813). In 1814 a Chinese professorship was specially created for R. in the Collège de France; he became editor of the *Journal des Savants* (1818), keeper of Oriental MSS. in the Bibliothèque Royale (1824), and President of the Société Asiatique (1829), which he had helped to found in 1822. He died of cholera at Paris, June 4, 1832. Amongst his numerous writings, where we discern no mere ingenious word-hunter, but one who sought to discover in speech the thoughts, manners, and history of the speaker, the principal are *Recherches sur les Langues Tartares* (1820), *Éléments de la Grammaire Chinoise* (1822), *Observations sur l'Histoire des Mongols Orientaux* (1832), and *Histoire du Bouddhisme* (1836). See Silvestre de Sacy's *Éloge d'Abel R.*

Remy. See REMIGIUS.

Renaissance (Fr. from Lat. *renascor*, 'to be reborn') is a term used to denote that glorious epoch of Italian history immediately succeeding the Middle Ages. It is commonly made to include entirely the 15th and 16th centuries; but within exacter limits it may be said to have begun with Petrarch, and ended with Leo X. The existence of the ecclesiastical state had made national unity in Italy an impossibility. Patriotism, and even the narrower jealousy of city towards city, had grown weary of the never-ended struggle for emancipation; the freedom now to be aimed at, it was felt, was the freedom of the individual. During the Middle Ages the glamour of early Christianity had become a mist, through which great men could not distinguish each other, and amid which the only voice distinctly heard was that of Papal authority. There was something noble in the faith which thus bound society together; but the childlike faith became more and more childish, and at length was seen to be simply illusion. The emaciated Christ, the sorrowful Virgin, and the entranced saints of the Middle Ages contracted too forcibly with the popes and nuns and priests of the republican times. The Church set the example of worldliness. Its servants were the first to revile and wag the head under the cross. Religion was dead: a new influence was to give second birth to the spirit of man. This R. had two distinct causes. There was the perception of the incompleteness of the Church's scheme of human life, with a consequent indifference to its authority. This contributed the element of freedom and individualism. But while this spiritual revolution was going on, the wind wafted precious fragments of classical literature to Italian shores from the conflagration of the Eastern Empire. To this literature the popular energies were directed. Had it been absent, the R. might have been a Reformation; but Calvary was deserted for Olympus, Galilee for Corinth.

Petrarch in his study, poring over almost undecipherable Greek manuscripts, like one striving to recall a dream, typifies the new-born Italy. In the article PETRARCH we have shown what the father of modern learning did for his age and all ages. Innumerable men of distinction followed his example. Pope Nicholas V., when a simple monk, crippled himself with debts incurred in the buying and copying of classical MSS. At his death he left a collection of 5000 volumes. Niccolò Niccoli, the Florentine, spent his entire fortune on books, and when he was himself bankrupt still continued to buy with gold provided by

Medicean munificence. Guarino and Poggio may be picked out from book-hunters for special mention. The latter in Southern Germany discovered six orations of Cicero, the first complete Quintilian, and made important additions to Silvius Italicus, Manilius, Lucretius, Valerius Flaccus, Asconius Pedianus, Columella, Celsus, Statius, and Aulus Gellius. Along with Lionardo Aretino he also unearthed the last twelve comedies of Plautus, and Cicero's *De Oratore*, *Verrine Orations*, and *Brutus*. Such was the work of salvage done by hundreds of rich and enthusiastic men at a time when to have neglected these literary treasures would have been to lose them for ever. The Greek scholarship of Petrarch and Boccaccio, meagre though it was, produced the richest fruits. Schools of Greek literature and philosophy—Plato's especially—sprang up everywhere. Florence, Rome, Padua, Verona, Ferrara, Venice, Perugia, Pavia, had all professors of Greek. Aldo Manucius of Venice, the great printer and editor, ventured his whole fortune in the cause of learning. And so successful was this movement, that towards the end of the 16th c. large numbers of Italian youths were accustomed to speak Greek fluently. The effect of this classical mania was not entirely good. For 200 years the highest aim of the best men was a pure Latin style; literature became the art of quotation. Petrarch had placed his hopes of fame on his Latin poems, which are universally neglected for his Italian; Poggio bewailed Dante's choice of the vernacular for his *Divine Comedy*. Yet we have to thank generations of men, content to be editors when they might have been authors, for the preservation of the old world. Their labours hindered but did not impair the development of the Italian language; they realised the dream of Dante, and gave him Virgil for a companion on the road to fame. These humanists, however, in one respect, left Italy even worse than they found it, for they abolished morals. Their Paganism was complete. Intoxicated with the sense of power, mental and physical, they devoted themselves to the enjoyment of each passing moment as an end in itself. Cosmo de' Medici sang, 'You follow infinite objects; I follow finite.' Lorenzo de' Medici wrote, 'We must enjoy: there is no certainty of to-morrow.' Leo X. summed up his theology by crying, 'Let us enjoy the Papacy, now that God has given it us.' Humanistic morals at their best might be exhibited in the words of Pope Julian II.—'If we are not ourselves pious, why should we prevent other people from becoming so?' It was this want of principle that ultimately extinguished the humanists as a class. They laboured unweariably in the cause of antiquity, but quarrelled among themselves; and when they had delivered up their honey, they stung each other to death.

Amid this carnival riot of the reason and the senses, a few stand almost immaculate. Such are the universal geniuses—Michael Angelo, the half-divine Hercules of art; Leonardo da Vinci, the exquisite dreamer; Alberti—athlete, lawyer, scholar, painter, sculptor, poet—a great-hearted, devout Christian. These in their wonderful lives justified the spirit of the R.; they stand like statues on its pinnacles.

In *Architecture*, the term R. is used to denote a style that originated in Italy in the 15th c. and spread over Europe in various forms. Its development in Italy is traced under ITALIAN ARCHITECTURE (q. v.). It was introduced into France by the Italian architect Fra Giocondo under Louis XII. (1461-83), whose Italian campaigns had familiarised Frenchmen with the style. From his reign and that of François I. date many of the finest specimens of the R. style, such as the Châteaux of Chambord and Chenonceau on the Loire, and the Church of St. Eustache in Paris (1532). While the Italian architects returned more or less completely to the Roman forms, the French clung at first to Gothic forms, and merely introduced classical details of ornamentation—pilasters, capitals, mouldings, cornices, &c. The style reached its perfection in France under Henri II. in the S.W. façade of the Louvre, parts of the Chateau of Fontainebleau, and other buildings. From the time of Henri IV. to that of Louis XIV. it became degraded, its form being nondescript, neither Gothic nor Classic, and its ornamentation both excessive and meaningless. Under Louis XIV., again, it somewhat revived, the Gothic form being entirely abandoned, and a more consistent, if often heavy and unimpressive style, being introduced. The great palace of Versailles, built by Hardouin Mansard, and the E. front of the Louvre, designed by Perrault, are the most notable buildings of this period. The R. style did not penetrate

into Germany until the middle of the 16th c. Among the most notable of its early examples are the Belvedere in the Hradschin of Prag, the Palace of Heidelberg (1556), and the Rathhaus of Nürnberg (1616). In Spain it was early adopted, and the town-halls of Saragossa and Seville, with many other buildings, are fine specimens of the style, which was afterwards considerably affected by Moorish influences. The earliest instances of R. architecture in England date from the latter half of the 16th c. By the engrafting of the Continental R. upon the Tudor and Old English styles, the ELIZABETHAN ARCHITECTURE (q. v.) was produced, and this was followed by the JACOBÆAN, of which the principal master was Inigo Jones, the architect of the banqueting-house of Whitehall, London, and Heriot's Hospital, Edinburgh. The Great Fire of London in 1666 made room for a great number of buildings in the purer R. style, most of which were erected by Sir Christopher Wren, the chief being St. Paul's Cathedral. Classicism predominated throughout the 18th c., in the beginning of which English architecture was greatly influenced by the ponderous style of Louis XIV. To this period belong such buildings as Blenheim House and Castle Howard, erected by Vanbrugh.

The beginning of the present c. was marked by a revival of the purely classical style. The R. architects had as far as possible adapted classical methods and details to modern requirements. Modern requirements were now made to adapt themselves as best they could to pure classical forms. Of this movement the Madeleine in Paris is perhaps the most remarkable result. Other examples are St. Pancras Church, London, St. George's Hall, Liverpool, the High School, Edinburgh, the Museum, Berlin, the Glyptothek, Munich, and the Walhalla near Donaustauf on the Danube. This movement soon gave way to a revival of the earlier R. style, and even of the Gothic, in such remarkable examples as the Houses of Parliament, London, and the Votive Church, Vienna.

The other fine arts of the R. have already been described in the articles PAINTING and ITALY. The roots of modern art strike deeper into the Middle Ages than do those of modern learning. The Church furnished the painters with subjects of which imagination was long in growing weary; when classical art was revealed, it did not conquer the ecclesiastical, but only blended with it. Thus the painter who depicted Mary fainting on Calvary turned to wed Ariadne to Bacchus with his brush. The quickening sense of bodily perfection led artists to the intensest study of anatomy. Here, indeed, they found the Greeks had been before them, but they laid hold of the beautiful everywhere. On their canvases the lean saints grow lusty and strong, the Virgin rivals Venus, and Christ, as Pulci observed, becomes 'a crucified Jupiter.'

See Tiraboschi's *Storia della Letteratura Italiana* (13 vols. 1772-83), Roscoe's books on the Medici, Reumont's *Lois de Medici* (1874; Eng. trans. 1877), Pater's *Studies in the R.* (1873), Symonds' *R.* (3 vols. 1877), Burckhardt's *Cultur der R.* (1869; Eng. trans. 1878), and Paul Lacroix's *Science and Literature in the Middle Ages and at the Period of the R.* (Lond. 1878). Consult also article MEDICI.

Renaix, a town of Belgium, province of E. Flanders 22 miles S.S.W. of Ghent by rail. It has important cotton and linen manufactures, besides brewing, distilling, tanning, bleaching, salt and dye works. Pop. (1874) 13,643.

Renan, Joseph Ernest, an illustrious critic, theologian, and philologist, was born 27th February 1823, at Tréguier (Côtes-du-Nord). Destined by his parents for the Church, he was sent at the age of sixteen to a seminary at Paris directed by the Abbé Dupanloup. After three years there he was placed under the Sulpicians, first at Issy for philosophy, then at St. Sulpice. He had now attained rare distinction in all subjects taught at the seminaries, especially in the study of Hebrew, but his attitude towards Christianity had shifted so much that in 1845 he left St. Sulpice. For a while he was *répétiteur* in a school, preparing himself for a university chair, but his independent spirit soon led him to prefer a less fettered position. His memoir *Sur les Langues Sémitiques*, which obtained the Volney prize in 1847, and that *Sur l'Étude du Grec dans l'Occident au Moyen Âge*, crowned in the following year, show the variety and exactness of his knowledge even then. He studied deeply theology, philosophy, philology, and history, out all with a view to explain the origin of Christianity from a

thoroughly naturalistic standpoint. In 1848 he published various essays, inspired by the boldest German philosophy, very aggressive in tone, and showing a much less just appreciation of Christianity than he afterwards attained. Among the more miscellaneous articles, that on the origin of language is specially noticeable. His *Histoire Générale des Langues Sémitiques*, expanded from the memoir mentioned above, appeared in 1854-56. The work, while deeply indebted to preceding inquiries, abounds in exact information and original views, and shows how lucid and elegant a hand at once firm and delicate can make the most erudite disquisitions. During this same period he contributed in 1851 and 1852 to the *Journal des Débats* and *Revue des Deux Mondes* articles in which subtlety and originality of ideas, deep and extensive learning, and beauty of style are equally striking. These essays he collected and published in two volumes with the titles *Études d'Histoire Religieuse* (1856) and *Essais de Morale et de Critique* (1859). On his return from a scientific journey in Italy in 1850, in which he gathered materials for an essay upon *Averroes et la Italie Averroïsme* (1852), he had become employé in the MS. department of the Imperial Library at Paris. In 1856 he was made a member of the Academy of Inscriptions, and soon after of the Commission of the Literary History of France. In 1857 his treatise on the origin of language was republished, and in 1859 appeared his translation of Job, with an introduction upon the age and character of the poem. The translation is perfect, combining throughout the severest faithfulness to the original with naturalness, fluency, and purity of form. The introduction, marked by clearness of thought, charm of exposition, and solidity of learning, is one of the most valuable aids we have to the understanding of the book. In the next year a similar work upon the Canticles followed, and R. was sent by the Emperor to Phœnicia and Syria on a tour of investigation, the results of which were afterwards published in his work the *Mission de Phénicie* (1864-67). On his return he was elected professor of Hebrew at the Collège de France, but fanaticism, irritated by the free tone of his opening lecture in 1862, finally secured his removal from his chair. In the controversy R. wrote a clever brochure, the *Lettre à mes Collègues*, in which he maintained his right, as Hebrew professor, to handle freely any theological questions. In 1863 appeared Part I. of his purposed great work on the *Origines du Christianisme*, the famous *Vie de Jésus*, a work of strange and various power, but rather an idyll than a history, the biography of an emotional visionary such as Shelley, rather than of the founder of anything great and permanent. He judges, as Scherer has said, a moral work in the spirit of a mere artist, and virtually denies Christ's integrity and purity. His portrait of Christ is 'unintelligible, inconsistent, and inadequate,' and though it may be admitted that in this work he sets forth the great problem of the origin of Christianity in a singularly direct, perspicuous, and intelligible form, none the less is it plain that his own Christ and early Christians are psychological impossibilities. The vigour, lucidity, chasteness, and picturesqueness of his diction, 'a blending of Victor Hugo and Lamennais,' cannot be too highly praised. In 1866 followed the *Histoire des Apôtres*, equal to the *Vie de Jésus* in pathos, in sweetness, and strength of diction, in consummate skill of grouping and painting, and in its fervour 'strong and strange,' 'an ardent adoration of something indefinite, dreamy, and ideal,' but with less verve, less thoroughly radical, 'conciliatory and even exquisitely courteous towards orthodoxy,' and deeply offending Liberal France by its admiration of Cæsaristic centralisation. In 1869 appeared Part III., *Vie du St. Paul*, and in 1873 Part IV., *L'Antichrist*. In the Franco-Prussian War R. came forward as a political writer against Prussian 'arrogance and ingratitude,' in an essay in the *Revue des Deux Mondes*, and a correspondence with Strauss. In 1876 appeared the *Dialogues et Fragments Philosophiques*, which sketch a whole philosophy or rather theology, and show in unabated vigour his three distinguishing qualities, 'exquisite charm of treatment, the most aristocratic scepticism as to traditional beliefs, and a constant effort to respond to the claims of the religious mind without contradicting science.' In 1878 was published Part VI. of the *Origines du Christianisme*. The 5th vol., entitled *La Seconde Génération Chrétienne, Les Évangiles*, is perhaps the ablest of the set, 'painting in marvellous colours the two centres in which the Gospels originated, showing consummate art in discriminating the characters of the four, and discussing with extreme delicacy the arranging and combinations which they underwent.' In 1878

appeared his *Mélanges d'Histoire et Voyages*, an interesting collection of articles published in reviews between 1847-75, and also his political satire *Caliban*, a continuation of the *Tempest*, in which Caliban triumphs, Prospero becomes his minister, and Ariel in despair dissolves into the elements. In June 1878 R. was elected a member of the French Academy. Other works of R. are his *Histoire Littéraire de la France au XIV^e Siècle*, in conjunction with Victor Leclerc, *Questions Contemporaines*, *La Part de la Famille et de l'Etat dans l'Education*, *La Monarchie Constitutionnelle en France*.

Reinburg (in the 12th c. *Reinoldesburg*), a fortified town of Prussia, in the province of Schleswig-Holstein, on the Eider and the Schleswig-Holstein Canal, 67½ miles N.N.W. of Altona (Hamburg) by rail. It consists of three parts, the *Alistadt*, *Kronwerk*, and *Neuwerk*; has two churches, an arsenal, and a 'Realgymnasium,' and manufactures brandy and tobacco. Pop. (1875) 11,406.

René, or **Renaudus I.**, of Anjou, Comte de Provence and Guise, Duc de Bar, titular Duc de Lorraine, and titular King of Naples, was born at Angers, 16th January 1409. He was a great-grandson of King Jean the Good of France and a grandson of Louis I. of Anjou, who, being the heir of Queen Joanna, had been crowned King of Naples by Pope Clement VII. (1384), but was supplanted by Charles of Hungary and Margaret his consort. Married at thirteen to Isabelle of Lorraine, he seized that duchy on the death of Charles, his father-in-law (1431), yet was overpowered and made prisoner by a nephew of the latter, Antoine of Vaudemont. Called to the throne of Naples by the testament of Queen Joanna II., he at first sent his wife thither to lead the struggle against Alfonso of Aragon. In 1437 R. was freed from imprisonment through pawning the duchy of Bar to Philip of Burgundy. The year following he appeared in Naples, where he maintained himself till 1442. By the marriage (1444) of his daughter Iolanthe with Frédéric, the son of Antoine of Vaudemont, Lorraine became a possession of Frédéric in 1444, and in 1470 of his son R. II. R. I., after having repelled the attacks of Charles the Bold on Lorraine and Provence, bequeathed the latter, on the death (1470) of his only son Jean, to King Louis XI., and died at Aix in Provence, 10th July 1480. R. was a lover of pastoral poetry, and himself a poet. His *Œuvres Complètes* were published by Quatrebarbes (4 vols. Par. 1845-46). His daughter is the subject of a drama by the Danish poet Hertz, translated into English by Theodore Martin. See La Salle, *Vie de R. I.* (Aix, 1820), Villeneuve de Bargemont, *Histoire de R. d'Anjou* (3 vols. Par. 1825), and A. L. de la Marche, *Le Roi R.* (Par. 1875).

Renfrew, a royal and parliamentary burgh on the banks of the Clyde, 6 miles W.N.W. of Glasgow, and 3 miles N.E. of Paisley by rail. The burgh was first chartered by Robert III. in 1396, and the R. Grammar School was founded by a charter of James VI. in 1614. The office of High Steward of Scotland was conferred by David I. on Walter, Laird of R., from whom the Stuart family is descended. A new townhall, opened in 1873 at a cost of £12,000, was destroyed by fire, 6th March 1878. The chief industries of R. are shipbuilding, engineering, and ironfounding. In conjunction with Kilmarnock, Dumbarton, Port Glasgow, and Rutherglen, it returns a member to Parliament. Pop. (1871) 5004. See *A Historical Sketch of the Burgh of R.* (Paisley, 1872).

Renfrewshire, a county of Scotland, bounded on the S. by Ayrshire, on the E. and N.E. by Lanarkshire, on the N. by the river Clyde, and on the W. by the Firth of Clyde. Pop. (1871) 216,947. Its greatest length is 31 miles and its greatest breadth 13 miles, the total area being 2545¼ miles or 162,428 acres; of which in 1876, 18,187 acres were under corn crops, 7360 under green crops, 18,556 in clover, sanfoin, and grasses in rotation, and 48,582 in permanent pasture, the preponderance of the last being due to the amount of dairy-farming carried on for the supply of the great towns of Glasgow, Greenock, and Paisley. In 1876 there were in R. 3128 horses, 25,090 cattle, 32,909 sheep, and 1917 pigs. The valued rental for 1877-78 was £609,755 exclusive of railways and public works, valued at £79,252. Along the banks of the Clyde and for some way inland R. is low-lying, undulating, and fertile, but further inland its surface is broken and unequal, though it does not rise more than 1240 feet above the sea level. Its only notable rivers are the Black Cart, the White

Cart, and the Gryffe, from which it took its ancient name of *Strathgryffe*. Coal, ironstone, shale, limestone, and sandstone are extensively worked, the chief coal mines being at Quarrieaton near Johnstone, at Hurlet and Househill near Paisley, and at Renfrew, Pollockshaws, &c. R. stands next to Lanark among the Scotch counties in the extent and importance of its manufactures, principally of silk and cotton goods, woollens, shawls, muslins, &c. Paisley (q. v.) is the centre of the manufacturing industries, but weaving is carried on in almost every village. Greenock and Port Glasgow are large and flourishing seaports, the other ports on the coast being Renfrew, Erskine, Gourrock, Innekip, and Wemyss Bay. R. is divided into Upper and Lower Wards, each of which has a sheriff-substitute, stationed at Paisley and Greenock respectively. In 1404 the barony of R. was conferred by Robert III., the second of the Stuarts, on his son and heir James, and since then the eldest son of the reigning monarch has always borne the title of Baron of R.

Rennell, James, F.R.S., an English geographer, was born at Cludleigh, Devonshire, 3d November 1742. He entered the navy at the age of fifteen, but after nine years of seafaring passed as an officer of engineers into the service of the E. India Company. For his conduct in Clive's campaign he was rewarded with the rank of major, and during this period he prepared his first publication, *A Chart of the Bank and Current of Cape Aguillas*, a work which at once attracted the attention of men of science, and secured him the congenial appointment of surveyor-general of Bengal. On his return to England he received a pension of £600, and was elected a F.R.S. He aided Mungo Park in preparing for his first great African expedition, and from this time maintained a correspondence with many of the most learned men of Europe. The best known of his many works are *Elucidations of African Geography* (1793-98), *The Geographical System of Herodotus Examined and Explained* (1800), *Observations on the Topography of the Plain of Troy* (1814), and the posthumous *Investigation of the Atlantic Currents* (1832). He died in London, 29th March 1830, and was buried in Westminster Abbey. Highly gifted with shrewdness and perseverance, R. pushed his way to fame in spite of a defective education and without the aid of friends or fortune.

Bennes, a river-port of France, capital of the department Ille-et-Vilaine, stands at the confluence of the Vilaine and Ille, and on the Ille-et-Rance Canal, 155 miles W. of Brest by rail. It consists of an upper and a lower town, the former dating from the fire of 1720, which destroyed 3284 houses. Among the chief buildings are the cathedral of St. Peter, the churches of St. Germain and Notre Dame, the Palais de Justice (1618), with paintings by Juvenet and Coppel, the Lycée, or Palais de l'Université, with picture and sculpture galleries, the theatre, and the Hôtel de Ville, containing a public library of 45,000 vols. The banks of the Vilaine are lined with quays, and there is a fine jardin des Plantes, besides the splendid promenades of Mont Thabor with a statue of Duguesclin, Le Mail, &c. R. is the seat of an archbishop, and possesses an arsenal and school of artillery. The leading industries are shipbuilding and the manufacture of sail-cloth, linen, leather, tobacco, starch, and soap, and there is a considerable trade in salt butter, honey, and wax. Pop. (1876) 57,177. The chief town of the Celtic *Redones* (hence its modern name), R. was formerly the capital of Brittany, with which it passed by marriage to François I.

Rennet. See REINETTE.

Rennie, John, F.R.S., a celebrated civil engineer, was born at Phantassie, East Lothian, June 7, 1761. He was educated at East Linton and Dunbar, and after working some time as a millwright, proceeded to Edinburgh, where he attended the lectures of Robison and Black. Recommended by the former, he entered the employment of Boulton and Watt, at Soho, near Birmingham, in 1780, and in 1789 he was appointed by this firm to superintend the construction of the Albion Mill. His reputation was now thoroughly established, and in 1794 he was recognised as the foremost engineer in the country. He especially excelled in the construction of bridges, of which the finest are Waterloo and Southwark Bridges. At various other places, Leeds, Boston, Musselburgh, Kelso, &c., are similar structures, which in elegance and solidity are unsurpassed. As an engineer of dockyards, harbours, canals, and railways, he also stood pre-eminent; and London, Hull,

Plymouth, Portsmouth, Liverpool, Dublin, Greenock, Leith, &c., furnish evidences of his talents in this respect. Perhaps the most remarkable of his naval works is the Plymouth Breakwater. R. died at London, October 16, 1821, and was buried in St. Paul's Cathedral.—**George R., F.R.S.**, eldest son of the preceding, was born in the parish of Christ Church, Surrey, January 3, 1791. Four years he studied at Edinburgh University, returning to London in 1811, where he became assistant to his father, after whose death he formed a partnership with his brother John (afterwards Sir John), and later with his two sons. He constructed many of the great naval works at Sebastopol, Cronstadt, Odessa, in Belgium, and at the various British ports; and executed besides several railways at home and on the Continent. He died in London, March 30, 1866.—**Sir John R.**, the brother of the latter, was born August 30, 1794. He was knighted at the opening of the new London Bridge (1831), a work executed by him, though designed by his father. He retired from his brother's firm in 1845, and subsequently won great celebrity as a civil engineer. He was recognised as one of the highest authorities on all questions connected with naval engineering, and was the author of a work on harbours. He died September 3, 1874. See *Autobiography of Sir J. R.* (1875).

Rent (Fr. *rente*, from *rendre*, 'to give back') is that portion of the product of soil which remains over and above the portions covering the expenses of cultivation. This may be taken as a fairly comprehensive definition of R.; but no definition has ever been agreed upon by any two economists. Feudal traditions envelop the relations of landlord and tenant so much, that we find difficulty in perceiving this, that R. is the result of a contract entered into voluntarily by both parties concerned. To hire a field is an act every way similar in principle to the hiring of a house or a ship. The true position of a landlord is not that of a patron, but that of a party to a contract, his peculiar qualification being that he is a capitalist.

It is from its productive agency that profits accrue to the proprietor of land; but land is not the only productive natural agent. The water of rivers turns this mill, the wind turns that. Yet, while all other natural agents are looked upon as practically inexhaustible, it is otherwise with land. No capital, no industry can be said to be expended on the sea or the wind; capital and industry are lavished upon land. Why, then, are capital and industry thus expended on the soil? In answer to demand. The productive soil has no value, except as producing that which satisfies some demand. There are rich tracts of cornland in the heart of Africa wholly valueless; nobody is in the least benefited by their fertility. Suppose a colony to establish itself in a tract of such land. The members of that colony will begin cultivation immediately; they will work on till food sufficient for the wants of all is secured. No further labour than this would they bestow upon the soil, because the fruits of such labour would remain unconsumed and useless. What each man received from the soil would exactly compensate his labour. But if a sudden increase of demand for corn arose, say in a neighbouring colony, the owners of the soil would probably do one of two things—they would work harder and sell their surplus produce, or they would allow others to cultivate the land, themselves stipulating for a certain proportion of the grain produced. Properly, we should call the first of these cases one of profit; the second, one of R. All that the proprietors might produce above what was necessary for their own maintenance might go for profit; all that the tenants might produce above what was necessary for their maintenance might go for R. Thus, cultivation must go on wherever there is a man, but appropriation of the soil only follows on demand in excess of that of him who appropriates. Whence it follows, that if a soil is capable of producing more than suffices for the maintenance of the labour expended upon it, it is capable of yielding R. Appropriation follows demand; R. follows appropriation.

Two important theories of R., differing widely from the account given above—which agrees with the most commonly accepted doctrines—are those of Bastiat with his followers, and Ricardo with his.

Bastiat's theory is that R. is only compensation received by the landlord for labour and capital expended at one time or other on the land. This theory was raised as a shield against the attacks of the socialists, who maintain that landed property is a

privilege, and should therefore be abolished. Bastiat replies that landed property is no privilege; that R. is no privilege, but a right similar to that connected with any other species of property; it bears no relation to natural agents, but applies exclusively to *services rendered*. Without going into details of this plausible theory, we may point to the example of a kelp shore or a gravel pit, upon which no capital or human labour was ever expended, to illustrate its fallacy.

Ricardo's theory is that R. is determined by the difference in the product of land of different qualities, the worst land in cultivation yielding no R. at all. An example may illustrate this doctrine. When colonisation takes place in any country abounding in fertile, unappropriated land, no R. is paid—no person would pay for what might be got for nothing. But when tillage has reached that particular stage at which demand can no longer be supplied by the best lands, either the increase of population must cease, or people must consent to pay such an additional price for corn as shall enable cultivators to bestow attention on inferior soils. Suppose that land of the first quality yielded 100 quarters per acre, and that of the second only 80. A farmer would generally be as willing to cultivate the first soil, giving 20 quarters by way of R., as to cultivate the second soil, subject to no claim for R. In either case, he himself would receive 80 quarters from the land. This increase of R. is not, as generally supposed, occasioned by improved agriculture, or by anything like a greater natural fertility in the soil. It results from the stress of population, which makes it necessary to resort to soils of a decreasing fertility. R. varies in inverse proportion to the amount of produce obtained by means of capital and labour employed in cultivation; it increases when the profits of agriculture diminish, and diminishes as these increase. Profits are at their maximum in new countries where good land is unappropriated; rents are at their maximum in old countries where even the worst soils are appropriated.

To detail objections to this doctrine would require great space. Suffice it to say that Ricardo's theory of R., like his theory of value, avoids a direct appeal to Demand. Ricardo in both cases makes cost of production a cause, whereas cost of production and value and R. are alike limited by the single determinant Demand.

Law Regarding R.—For legal modes of enforcing payment of R. after it becomes due, see, in English law, DISTRESS, EJECTMENT. On the same subject in Scotch law see POINDING, EJECTION AND INTRUSION, and in both cases the articles referred to in these. By 33 and 34 Vict. c. 35 rents and tithes, and payments in place of these, are, after 1st August 1870, held to accrue from day to day, and are apportionable accordingly; an accrued part not becoming due until the whole would have been so. See LANDLORD AND TENANT. A tenant must continue to pay rent though the premises in respect of which it becomes due are burnt, and the landlord refuses to rebuild them. See REPAIRS.

Ren'ton, a small town on the Leven, in Dumbartonshire, 3 miles N. of Dumbarton, was founded by the Smolletts of Bonhill in 1782. Tobias Smollett, the novelist, was born in its neighbourhood, and a monument has been erected to his memory in the town. R. has considerable calico-printing, bleaching, and dyeing industries. Pop. (1871) 3087.

Renuncia'tion. In English law the term is only applied to denote the refusal of an executor to accept office. The R. should be made by a letter to the Court of Probate. In Scotland, R. by an heir means his declining, which he is entitled to do, to accept an inheritance, the acceptance involving liability for debt attached to the subject. See ANNUS DELIBERANDI. R. of lease or other right is equivalent to *surrender*.

Ben'wick, James, a preacher and martyr of the Covenant, was born of humble parentage at Minnith, Dumfriesshire, 15th February 1662. He attended Edinburgh University, but was refused a degree on declining to take the oath of allegiance, and after witnessing the execution of Cargill in 1681, he threw in his lot with the Covenanters. At the request of the 'Society Men' he went to Holland, and was ordained at Groningen, immediately afterwards returning to Scotland, when he preached his first public sermon on Darnead Moss in 1683. His life now became one of incessant danger, as he rapidly passed from place to place throughout the S.W. of Scotland, preaching, counselling, corresponding, and issuing manifestoes. On the proclamation of

James II. in 1685, R. and 200 men went to Sanquhar, and published a declaration disowning him as a Papist, and throwing off allegiance. In 1687 a sum of £100 was offered for the capture of R. dead or alive, and in less than five months fifteen furious searches were made for him by dragoon parties. After many wonderful escapes he was at last taken in Edinburgh, where, in spite of his youth and nobility of character, he was speedily condemned, and executed 17th February 1688, his last words being drowned by the beating of drums. See *Life of R.* by Alexander Shields, a contemporary; also *A Choice Collection of very valuable Prefaces, Lectures, and Sermons, preached upon the Mountains and Muirs of Scotland, in the Hottest Time of the Persecution*, by Mr. James Renwick (Glasg. 1777).

Rep (probably a corruption of *riù*), a woollen fabric so woven as to present a ribbed appearance transversely. It is used for ladies' dresses. Any stuff exhibiting this feature is said to be *repped*.

Repairs (in law). If a tenant agree to make repairs, and the premises are burnt, wholly or partially, he is bound to replace them, unless there is a contrary stipulation. He is not, however, bound to replace damage done by natural casualty. See **ACT OF GOD**. In England, the burden of making R. is by common law laid on the tenant; in Scotland it falls on the landlord, unless they have become necessary through the tenant's fault. In English Church law, see **DILAPIDATION**.

Repeat, in music, a sign that a portion of a composition is to be played or sung twice. The part to be repeated is indicated by dots, sometimes two  and sometimes four 

being used. The words *Da Capo* (*D.C.*) signify that the repeat is to be from the beginning, and if the entire passage is not to be again performed, the word *fine* points out where the repetition is to end. The words *Da Segno* (*D.S.*) are used instead of *Da Capo* when the repeat is to run from another point than the beginning, such point being marked §. An alteration is sometimes made the second time, thus:—

When a few bars are to be repeated they are marked *bis*.

Repetition, in Scotch law, means repayment of money erroneously paid. See **CONDUCTIO INDEBITI**.

Replevy and Sale. In English law, a replevy is an action to test the legality of a Distress (q. v.) and to recover the goods distrained. As the action may involve a tenant in an expensive and protracted lawsuit, it ought to be very cautiously attempted. To replevy, the tenant whose goods have been distrained, must, within five days after notice of distress has been given to him, enter into a bond, with two sureties, for double the value of the goods, to try without delay the right of distraining, and to return the distress should the case go against him. The judge will then direct a precept to a bailiff to restore the goods to the tenant.

Replication, in English law, is the pleading of the plaintiff in answer to the plea of the defendant.

Reporting, Parliamentary. Prior to the practice of P. R. the discussions of the House of Commons were scarcely more known to the public than those of the Cabinet Council, and it was only after a long and arduous struggle that the Legislature allowed an unchallenged record of its debates to appear in the press. The work which gives the most methodical and complete record of the proceedings of ancient English Parliaments is Cobbett's *Parliamentary History of England*, which forms a historical introduction to Hansard. When we consider that the first volume of this series embraces the period of time from 1066 to 1625, while Hansard's *Debates* for a single session comprise several volumes of the same size, we can understand the revolution worked as regards the publicity of parliamentary proceedings by the institution of regular reporting. The *Parliamentary History* was compiled from numerous disjointed authorities, such as the *Records*, the *Rolls of Parliament*, English histories, a former

Parliamentary or Constitutional History, first published in 1751, the *Journals* of the two Houses, containing the votes and proceedings of the House of Lords from the reign of Henry VIII., and those of the House of Commons from the reign of Edward VI., and Sir Symonds D'Ewes's *Journal of Queen Elizabeth's Parliaments*. The *Proceedings and Debates of the House of Commons* in 1620 and 1621, collected by a member of that House, published at Oxford in 2 vols., were incorporated in Cobbett's work. Rushworth, assistant-clerk in the Long Parliament in 1640, made notes of the principal speeches he heard, and embodied them in his *Historical Collections*. A series of *Debates of the House of Commons* from 1667 to 1694, collected by the Honourable A. Grey, M.P. for Derby, is an important historical contribution in 10 volumes. In most of these works much of the material consists of papers laid before Parliament of mere momentary utility, and having a very remote connection with the valuable proceedings of Parliament. A member sometimes transmitted accounts of proceedings privately to his constituents. The famous Andrew Marvell supplied Hull for example with daily information of this kind from 1660 to 1678. It was not till the end of the 17th c. that meagre Parliamentary reports furtively found their way into the public journals, being sent thither by some adventurous members. In 1698 the attention of the House of Lords was called to the innovation, which they declared to be a breach of privilege. The House of Commons expressed itself similarly in 1723, and adopted a resolution to punish offenders in future with the utmost severity. This determination was not however actively carried into practice, and in 1735 two publications, the *Gentleman's Magazine* and the *London Magazine*, began to give more elaborate accounts of the debates than had ever been attempted. The names of the speakers were suppressed, with the exception of the first and last letters, a transparent device, but sufficient to postpone the wrath of Parliament for some time. According to Sir John Hawkins, the *modus operandi* of Edward Cave, the proprietor of the *Gentleman's Magazine*, was to obtain admission along with his assistants to a concealed station in the House, where they took down notes of the several speeches, and the general tendency and substance of the arguments. This crude matter was adjusted and embellished by William Guthrie, the historian, who seems sometimes to have attended himself, and who possessed a most retentive memory in addition to his other abilities. The reports did not appear till the end of the year, and thus six months sometimes intervened before the account of a debate was published, proceedings in January not appearing in print till July. On April 13, 1738, the House of Commons again characterised the publication of debates as a 'high indignity and notorious breach of privilege;' though, by the irony of circumstances, a most full account of the debate upon this motion, which was unanimously adopted, will be found in the *Parliamentary History*. The magazines therefore resorted to the expedient of describing the debates as if they had occurred in a fictitious assembly. Thus the *Gentleman's Magazine* headed its account as the 'Debates in the Senate of Lilliput,' and the *London Magazine* gave the proceedings as the 'Journal of a Political Club,' a key to the names of the speakers, &c., being duly supplied in both works at the end of the year. On the 19th November 1740, Dr. Johnson succeeded Guthrie as the writer for the *Gentleman's Magazine*, and he continued to do the work till 23d February 1743. Boswell informs us that Johnson had sometimes 'nothing more communicated to him than the names of the several speakers and the part which they took in the debate,' so that when we consider the imagination of the Doctor, and the grandiloquent style of his reports, we cannot accept the latter as very literal. But it is certain that Cave was at considerable pains to secure accuracy, and that speeches were frequently furnished to the members themselves to correct. Johnson was succeeded by Dr. Hawkesworth, author of the *Advertiser*. Cave and Thomas Astley, the printers of the *London Magazine*, were ordered into the custody of Usher of the Black Rod in 1747, charged with reporting the trial of Lord Lovat before his peers in 1745. But though they were reprimanded and had to pay fees, implore pardon, and promise amendment, Cave after a short while resumed his reports of the Lords' debates. In 1704 the House of Lords fined the proprietors of the *London Evening Post* £100 for mentioning the name of one of its members, and in several succeeding sessions printers of newspapers were fined for similar offences. Four

printers, including Woodfall of the *Public Advertiser*, were reprimanded by the House of Commons in 1766. Meanwhile public feeling became aroused, and so strongly did it declare itself in favour of the reporting of debates, that newspapers continued the system with increasing energy, while Parliament winked at the daily breach of its privileges. Among the most determined advocates of the rights of the press at this juncture were Horne Tooke and John Wilkes, and it was on the occasion of the latter's notorious struggle with Parliament that the final storm burst in which a complete victory was won by journalism. After a fierce night's debate on 12th March 1771, in which twenty-three separate divisions were taken on the subject, eight printers were summoned before the bar of the House of Commons, none of whom obeyed. The city magistrates were in sympathy with the public, and discharged three of the offending printers who were brought before them. For this contempt of Parliament the Lord Mayor and Alderman Oliver were committed to the Tower, and the clerk of the City was compelled to tear out the leaves of the register containing the judgments of the magistrates. On the other hand, the City authorities sent to prison the officers who had arrested Whible, one of the printers. The popular excitement was intense, but after a time the House gave up the struggle, and thenceforward made no attempt to punish the practice. Reporting the debates still remained theoretically a breach of the privileges of Parliament, but the right of the public to be present through their agents was clearly established. The House has therefore since this time taken no notice of the breach except when a report has been manifestly unfaithful, as in the case of a paper in 1801. The printers of the *Times* and the *Daily News* were summoned before the bar of the House of Commons so late as 1875, but it was with regard to an entirely different question, viz., the publication of matter relating to evidence given in a select committee of the House.

Among the ablest of early Parliamentary reporters was 'Memory' Woodfall, of the *Morning Chronicle*, who is said to have been able to write out accurately a column speech without a single note. His successor, John Perry, was the first to establish a regular relay of reporters who took up the work at short intervals. Thus a reporter found time to write out his notes in full while his colleagues continued the note-taking, and a full report of the debate was in writing almost immediately after its termination. The practice became after a time universal among other papers, and it is still in use. During the last century, reporters had no means of entering the gallery beyond those within the reach of the general public, and on important occasions had to push their way through the crowd. On the occasion of a great debate, shortly before the death of Pitt, they struck, so to speak, on account of the bad accommodation, and the Minister's brilliant periods were unreported. The result was the appropriation of the uppermost bench of the gallery, with a separate door, to their exclusive use, and a reporters' room was subsequently added. Soon afterwards the Lords followed the Commons' example. For a long time note-books were forbidden to be shown at the bar of the Upper House, and Mr. Windyer was the first reporter who defied the rules in this respect. When the new Houses of Parliament were built, separate rooms were given to reporters, exclusive of the reporters' galleries facing the woolsack in the House of Peers, and behind the chair in the House of Commons.

After the close of the great war in 1815, public opinion became concentrated more on domestic than on foreign affairs, and the consequence was an increased demand for parliamentary intelligence. The reports became still more voluminous at the time of the Reform agitation, and in Barrow's *Mirror of Parliament*, for which members corrected their speeches, very full accounts were given. In England the public appetite for debates seems somewhat to have slackened of late years, though it is as great in Scotland as ever. Parliament, however, with the great addition of public business, has become more loquacious. Thus in 1841, 231 members took part in the debates, while the number in 1876 had increased to 385. The practice of reporting has had a marked effect on parliamentary eloquence. Before its institution an orator on a momentous occasion addressed an audience of men more or less labouring under feelings of temporary excitement. He was then tempted to declaim in a heightened or exaggerated vein, or to try like a parliamentary Orpheus or Pimper of Hamelin to charm members to follow him into the lobby by the single sweet-

ness of his eloquence. But under present circumstances he is compelled to think less of a momentary than a permanent triumph. He addresses the calm, reflective judgment of the country, and speaks with the knowledge that his arguments will go forth to the world accompanied by full commentaries and searching criticisms in the columns of the public press.

Of 74 reporters regularly engaged in the House of Commons in the year 1877, 15 were employed on the staff of the *Times*, 9 on the *Standard*, 8 each on the *Daily News*, *Morning Advertiser*, and *Morning Post*, 6 on the *Daily Telegraph*, and 5 on the London evening papers, while the remainder represented the various news agencies that supply the provincial papers. These gentlemen were also available for duty during the brief sittings of the House of Lords, but when important debates were proceeding in both Houses, extra reporters were engaged. The parliamentary intelligence of the *Times* and *Standard* in particular enjoys a deserved reputation. The reporting staff of each paper is under the direction of a leader, who is the medium of communication between them and the office, and who in most cases writes the summary. The reporters take turns in the gallery, varying in length according to the importance of the debate or speaker, and transcribe their notes in dingy rooms behind the gallery and under the ladies' gallery, or else in one of the committee-rooms in the House of Commons. They have a good, well-fitted writing room in the House of Lords. Most newspapers have communication by telegraph with the Houses of Parliament—indeed one paper (the *Daily News*) has recently introduced a telephone—but the wires are not used for the transmission of the reports, which are sent by messengers and cabs to the offices. Wonderful as the results obtained are, we cannot look upon the present system of newspaper reporting as perfect. Public journals are, after all, commercial speculations, and their proprietors must suit, like all other business-men, their own interests and the tastes of their clients. They will not perform work at a loss, nor print what few care to read. Much therefore remains unreported, important discussions on supply and committees on bills are often scarcely noticed, while the despatch of newspapers to the provinces by the early morning trains forbids justice being done to the speeches after midnight. Probably, if the chief provincial newspapers were admitted to the gallery, there would be greater efforts even in this respect, while the reports would certainly be improved. As regards accuracy, Mr. Gladstone recently observed that he was better reported in the provinces than in the House of Commons. This is probably accounted for by the fact that in public meetings the reporters are placed close to and in front of the speaker, whereas in the House of Commons the gallery is some 20 feet above the level of the floor, and the members often speak with their backs to the representatives of the press. That the reports are as excellent as they are is a marvel, considering the difficulties of the task. The duties of a Parliamentary reporter demand abilities of a high order, readiness, invention, endurance, intelligence, and memory, besides a special and severe training. He must not only be a complete master of shorthand, so as to write a verbatim report, but must be able to seize the salient points of a di-jointed speech, to condense a wandering harangue into a practical form, and to state elegantly what has often been expressed most awkwardly. There are few professions of so restricted a nature which have been adorned by so many men who have subsequently attained eminence. Lord Campbell and Charles Dickens, the latter of whom when engaged on the *Morning Chronicle* was one of the fastest writers on record, have not been the only occupants of the reporters' gallery who have made their names illustrious.

Until the year 1875 it was within the power of any member of the House of Commons to obtain the withdrawal of reporters on his calling the attention of speakers to the presence of strangers. On the 27th of April in that year Mr. Biggar took this step. On the motion of Mr. Disraeli the suspension of the rule during that sitting was adopted, and the incident led to its alteration. It is now necessary to obtain a vote of the House on the question of the withdrawal of strangers. A division on the subject was balked in 1876 by a count-out, and the first actual division took place on 12th April 1878, when, on Mr. King-Harman's motion, strangers were excluded for three hours during a discussion on the assassination of Lord Leitrim. A summary of the proceedings while the reporters were absent was furnished by members to the press.

The annual publication of *Hansard's Parliamentary Debates*,

begun in 1803, has been conducted with such tact that they have improved every year. They are compiled from the daily papers and local reports, corrected by the members themselves, and though not authoritative, their accuracy has rarely been disputed. The question has, however, lately arisen in the House whether the matter should be left to private enterprise, or whether official verbatim reports ought not to be provided by a staff of reporters employed by Government. In proposing a motion to the latter effect on April 10, 1877, Mr. Hanbury Tracy estimated that six reporters and six writers in front of the speaker would meet the want at an annual cost of about £15,000. The motion was lost by 152 votes to 128. A Select Committee of the House of Commons sat in July 1878 to consider the question of P. R., both with regard to the desirableness of an official report, and the necessity of other newspapers than those published in London being represented in the gallery.

In the United States official reports are published, every senator being allowed two copies of the *Congressional Record* for his own use, and twelve for distribution. Such reports have also been adopted in Victoria, Queensland, New Zealand, and other British colonies. In most foreign countries the official are the only reports, newspapers being unrepresented at the debates. In France, where the Assembly meets early in the day, the official reports, which are of three kinds—one *in extenso*, a summary, and a very short report—are corrected by the deputies within five hours. The official reports are sold to the daily press, and a similar system is followed in Austria and Germany, and was adopted by the late Turkish Parliament.

Reports, Law. These comprise the decisions on legal issues preserved in the archives of the various divisions, and communicated to the public in numerous volumes. They contain a narrative of each case, a summary of the proceeding, the argument on both sides, the judgment, and the reasons for it. The R. are extant in a regular series from the reign of Edward II. inclusive. From his reign to that of Henry VIII. they were taken by the protonotaries, or chief scribes of the court, at the expense of the crown. From the reign of Henry VIII. to 1865 they were taken by private persons; a system which led to great inaccuracy. In 1865 an improved system was instituted, under the superintendence of the Council of Law Reporting, since incorporated. The statutes are hardly less voluminous. A revised edition of those now in force is in course of publication. See ACT OF PARLIAMENT.

Repoussé (Fr.) is an art term applied to ornamental metal work, produced by hammering or beating up the sheet of metal from behind until a design is roughly formed, then working on the front, and finishing the work by the process of chasing. Metal objects were worked in R. by the ancients, and all through the middle ages; and in the 16th c. this artistic process received its highest development in the hands of Benvenuto Cellini and other artists, who produced vases and figures in gold and silver, and pieces of armour in steel and iron. Of late years a revival of the higher flights of R.-work has taken place in England and France, and some works of art of extraordinary beauty have been executed.

Representa'tion, in politics, the method necessarily adopted in all states of any extent for obtaining a formal expression of the popular will. It is not employed exclusively in democratic constitutions. Many ecclesiastical assemblies have been representative, and even in absolute monarchies R. is sometimes brought into more or less limited play. It is best seen, however, in democratic forms of government. An ideal, or 'pure' democracy, as it is called, is that in which every citizen has a direct and independent voice in the national councils. This is only possible in very limited communities. When the political unit is of such size that it is impossible for all the citizens to attend frequently or at all in one place, the necessity for R. arises. A stated number of citizens, or those inhabiting some particular place, choose one or more *representatives*, to whom they delegate their political rights and powers. 'Experience shows,' says Mr. E. A. Freeman, 'that the purely democratic system which does such great things for a wandering

band, a single city, or a small district, becomes out of place when it is applied to all the inhabitants of a large country. . . . The representative assembly is as much the natural form of free government for the greater society as the primary assembly is for the smaller.'

R. was little, if at all, developed among the ancients. It must not be thought that wherever there is *election* there is R. The elective officials of Greece and Rome were in no sense representative, their functions being purely executive. In Greece R. was in most cases rendered unnecessary by the small extent of the political units. In Rome, when her empire began to extend over Italy, the need of R. was severely felt, but it was never introduced. The earliest instance of a complete system of R. is to be found in the parliament of the Sicilies, under the Swabian dynasty, in the 13th c. The growth of the representative system in England is traced in the article PARLIAMENT (q. v.). In Scotland, representative burghs formed part of Robert Bruce's national assembly at Cambuskenneth in 1326, but it was not till 1587 that R. was permanently introduced, and even then to a very limited extent. Down to a very late period in British history, the purposes of the representative system were in many instances defeated by 'pocket boroughs,' 'rotten boroughs,' and aristocratic pressure and influences, but these abuses have been largely done away with by the Reform Bills of 1831 and 1867. R. now plays a more or less important part in the government of every European country except Russia, as well as in that of the United States and in almost all the British colonies.

The theory of R. generally received at present is that the representative should not give pledges to his constituents as to his action on any particular question—that he should not be merely their mouthpiece, but that, once elected, he should act on his own responsibility, with due regard, of course, to their interests and wishes. Mr. Mill, however, admits that it is almost impossible to prevent pledges being demanded and given. Another point on which speculative politicians have expended much ingenuity is how to secure the *Proportional R.*, as it is called, of minorities as well as majorities. This is so far secured by the system of *three-cornered voting* (i.e., where there are three vacancies giving each voter only two votes), or by that of *cumulative voting* (i.e., allowing voters who have more than one vote to give them all to one candidate). Both of these systems are in use in England, either in parliamentary, municipal, or school-board elections, but they are at best very rough means for their end. See Mill's *Representative Government* (1861), Hare's *Treatise on the Election of Representatives* (1859), Professor Fawcett's *Mr. Hare's Reform Bill Simplified* (1860).

Reprieve (from Fr. *repandre*) is, in law, a suspension of a criminal sentence. It may be before or after judgment. If the judge doubts the justice of a verdict, or the validity of the indictment, he may stay sentence to give time for consulting the Crown; and after sentence the Crown may grant R., which generally proceeds on the recommendation of the jury, usually substituting a minor punishment to that which has been awarded. Insanity, or pregnancy, if proved, is always held to be valid ground for R.

Repri'sal (Fr. *représaille*; Low Lat. *reprénsalia*, 'things seized back,' from *reprandre*) is the retaking of goods captured by an enemy, or of an equivalent. A ship retaken is a *reprise*. It becomes the property of the recaptors if more than twenty-four hours have passed since the original seizure; otherwise it must be wholly returned to the owners.

Repri'sal, Letters of, the same as *Letters of Marque*. See LETTER.

Reprobation is the name given to a doctrine alleged to be involved in the Calvinistic doctrine of Election, but repudiated by Calvinists in the sense sought to be given to it. The word R. does not occur in the *Confession of Faith*, but the following language seems sufficiently explicit: 'By the decree of God, for the manifestation of his glory, some men and angels are predestinated unto everlasting life, and others foreordained to everlasting death' (chap. iii. sec. 3). Yet in sec. 7 of the same chapter it is further stated that it hath pleased God 'for the glory of his sovereign power over his creatures, to pass by, and to ordain them (the non-elect) to dishonour and wrath for their sin, to the praise of his glorious justice.' The phrase 'for

their sin' is held to introduce the moral element that clears the doctrine of the character ascribed to it by its adversaries.

Reproduction, the act of producing new organisms or beings in the animal and plant worlds. This process may be regarded as initiating the process of *Development* (q. v.), or that through which the germ or egg becomes transformed into the likeness of the being which gave it birth. The function of R. in plants is effected by means of the *essential organs* of the flower—these organs being the *stamens* and *pistil*. The *envelopes* of the flower (*calyx* and *corolla*) help by their colour, odour, &c., to attract insects to the plants; the insects carrying the *pollen* from the stamens of one flower to those of another flower of the same species, and thus effecting the *fertilisation* of the *ovules*. When the pollen of the stamens is applied to the *stigma* of the Pistil (q. v.), a *pollen-tube* is produced by the growth and elongation of the inner coat or *intine* of the pollen-grain. This pollen-tube passes down through the style of the pistil, and brings the matter of the pollen-grain in contact with the ovules, the result of this contact being the fertilisation or impregnation of the ovules. After fertilisation the ovules become 'seeds,' and are then capable, when placed in suitable circumstances, of growing up each into a new plant. The ordinary course of R. in plants is closely paralleled by the true *sexual* R. of animals. Here we find, as in plants, the elements of sex operating to secure the fertilisation of the egg or germ. The male organ (*spermarium*) of the animal supplies the *spermatic fluid* for the fertilisation of the product of the female generative organs—the *ovum* or *egg*. The stamens of the plant are thus comparable to the *spermarium* of the animal; while the pistil of the plant is the analogue of the *ovary* or *ovarium* of the female animal. In all groups of animals save the *Protozoa* (q. v.), *true* or *sexual* R. occurs, and some authorities maintain that even in the *Protozoa* this process is truly represented. The *nucleus* of these lowest forms is thus believed to represent an ovary; whilst the *nucleolus* is thought to represent the male organ of higher animals. In all animals the essential act of sexual R. is thus seen to consist in the contact of the male and female generative products. This contact is effected in very varied ways. In many lower animals, and even in higher forms (e.g., Fishes and Amphibians) there is no coition or copulative act. The male simply sheds the seminal fluid over the eggs of the female, and in some cases the male fluid may simply be discharged into the surrounding water, and fertilisation of the eggs may be largely a matter of chance. Where *Hermaphroditism* (q. v.) occurs, the act of fertilisation is rendered one of simple performance, but some hermaphrodite forms (e.g., Leeches and Snails) require to be impregnated by their hermaphrodite neighbours to ensure fertilisation. In such a case the male generative organs of the one form fertilise the female organs of the other; the female organs of the first being in turn fertilised by the male organs of the latter. In all Vertebrate animals, the sexes are situated in distinct individuals; hermaphroditism being only found in cases of monstrosities. Many Invertebrates (e.g., Insects, Spiders, Crustaceans—excepting the *Cirripedia*—Cuttlefishes, &c.) exemplify as complete a separation of the sexes; while among hermaphrodite or monœcious forms may be cited the Snails, certain Lamellibranchiata, many Brachiopods, Sea-Squirts, Polyzoa, Earthworms, Leeches, &c. In certain fishes (e.g., Dogfishes, Skates, and Rays) the embryos or young are enclosed in curious *egg-capsules* formed of a horny material resembling scaweed in its texture. These capsules are frequently cast up on our coasts, and are popularly known as 'Mermaid's Purses.' Some Molluscs (e.g., the Cuttlefishes and Whelks) also enclose their eggs in protective sacs termed *rudamental capsules*. In Mammalia, the act of R. necessarily becomes more complicated than in other groups, conformably with the more elaborate process of development through which these animals pass. The chief subject of interest, in connection with the R. of the highest group of animals, has already been noticed in the article PLACENTA (q. v.).

In the animal world certain *asexual* processes of R. also occur. Into these the elements of sex do not enter. They are known under the terms *fission* and *gemination*. By *fission* is meant the simple division of the body of an animal into two or more parts, each of which becomes in due time a perfect animal. In such a case the ordinary processes of *nutrition* and *growth* serve to reproduce the new forms which have been outlined, as

it were, by the division of the parent-body. Such a process is well exemplified in many *Protozoa*, such as *Amœba*, *Infusoria*, &c. The case of the *Hydra*, a freshwater Polype, which, as Tremblay showed in 1744, may be divided artificially into numerous parts, and perfectly reproduce its like, is paralleled by that of the sea-anemones or *Actinia*, which possess equally great separative powers. In some worms (e.g., *Nais*) the body may be seen to divide spontaneously into two or more parts, a new head having been previously formed on the detached portion. Corals also exhibit the process of fission. It is obvious that the asexual process of R. by fission can only occur in animals of low organisation, whose tissues are equally vital throughout, and which can therefore bear, without any permanent injury, an amount of mutilation which would destroy animals of higher structure. The second form of asexual R. is that known as *gemination* or *budding*, and is described under the latter heading.

Rep'tiles (Lat. *reptilia*, from *repto*, 'I creep'), a class or group of Vertebrate animals, nearly allied to Birds. In modern systems of classification the *Reptilia* are included with birds (*Aves*) in the *Sauropsida* (q. v.). The distinctive characters of the *Reptilia* are as follows:—The *exoskeleton* never consists of feathers, but of bony plates or horny scales. In some cases, scales and plates may co-exist. The *endoskeleton* is always osseous. The breathing-organs are lungs. Gills or *branchiæ* are never present in R.—hence a first distinction between R. and such animals as the frogs, newts, &c. The latter have gills in early life, and some *Amphibians* may have gills co-existent with lungs in adult life. But no reptile is provided with gills at any period of its existence. The heart of R. is three-chambered, save in crocodiles, in which there is an additional chamber. The skull is articulated to the spine by a single process or *condyle*, as in birds; mammals and amphibians having two condyles. The lower jaw of R. is a *compound* bone. Each half consists of a number of pieces which are ossified together in the adult. The lower jaw further articulates with the skull by a *quadrate bone*, the *os quadratum*, represented in mammalia by the *malleus*, or one of the small bones of the internal ear. The blood of R. is cold, and the red blood corpuscles are nucleated, as in birds; but the lungs of R. are closed sacs (as in mammalia), and do not, as in birds, open into *air-sacs*. In some R. (as in Snakes and the Blind Worms), all four limbs may be wanting. Some snakes (e.g., Boas) exhibit rudiments of the under pair of limbs, while some lizards may be provided with but one pair. But in the great majority of R. the limbs are well developed, and in certain extinct R. (e.g., *Pterodactyles*, q.v.), the fore limbs were modified for flight. It may thus be seen that R. differ from birds chiefly in the fact that they are cold-blooded, that they want feathers, have closed lungs, and have not the anterior extremities modified for flight.

The *exoskeleton* of R. consists, as has already been remarked, of scales and bony plates. In *Crocodylia* both structures exist, but scales alone form the characteristic covering of other R. In the *Chelonina* (Tortoises and Turtles) the skeleton itself is greatly modified, and along with the exoskeleton of scales forms the well-known bony case in which the bodies of these animals are contained. The scales are developed from the *dermis* or true skin, and are covered by *epidermal cells*. It is this epidermal covering which is shed or cast in the moulting process of many serpents. The *spine* of R. may (as in Serpents) be extremely long. In *Crocodylia* the skeleton is very complete, and includes most of the structures and parts regarded as typical of the vertebrate axis. The peculiarities of the reptilian skull have been already referred to. The *centra* or bodies of the Vertebrae in R. may be hollow at either end (*amphicelous*), *procelous* (hollow in front and convex behind), or *opisthocelous* (the reverse of 'procelous'). The *sacrum* of R. is provided with *sacral ribs*, the *ilia* of the pelvis articulating with these ribs. The 'hand' of R. consists of more than three digits, and the toes are never fewer than three. The metatarsal bones are not united by ossification, nor are they connected with the lowermost tarsal bones; while in birds the *astragalus* of the ankle is united to the lower end of the *tibia* or shin-bone, and the ankle-joint of the bird thus ceases to exist in the middle of the *tarsus* or ankle. The disposition of the quadrate bone of R. differs in the various orders. In some genus (e.g., *Chelonina*) the quadrate bone is finally ossified to the skull. But in serpents the quadrate is a mobile bone, and through its mobility permits

the great extension of the jaws, and thus aids in the enlargement of the mouth. In all reptilia save the snakes the various regions of the spine and trunk can be clearly defined. The *digestive system* of R. is of a complete character. It includes an oesophagus, a simple stomach, and a large and small intestine. The intestine terminates in a *cloaca*, a common chamber also receiving the efferent ducts of the urinary and generative organs. The walls of the stomach of *Crocodylia* are highly muscular and probably serve to triturate the food. The liver is well developed, and there is a gall bladder. The heart is *three-chambered*, and consists of two auricles and a ventricle in all R., save the *Crocodylia*, in which the single ventricle becomes divided by a complete *septum* or partition into two cavities, thus converting the crocodilian heart into a four-chambered organ. The *circulation* in all R. (inclusive of the *Crocodylia*) is, however, impure or mixed in its character. The pure blood from the lungs passes into the left auricle and thence into the ventricle; the impure blood from the veins passes into the right auricle and thence into the ventricle. It follows that a mixture of arterial and venous blood takes place in the ventricle, this latter cavity by its contraction sending the mixed blood partly to the lungs for purification, and partly to the system for nutritive purposes. In birds, as in mammalia, the venous and arterial blood-currents are never mixed, but are kept distinct throughout the entire extent of the circulation. The same imperfect circulation obtains in the *Crocodylia*, the blood currents in which, however, not being mixed in the ventricle, but in the great blood-vessels (*right and left aortæ*) in the neighbourhood of the heart. Between these vessels a communication (the *Foramen Panizzae*) exists, and the impure blood from the right ventricle thus mixes into the pure blood which is being driven from the left ventricle to nourish the body. The *breathing organs* of R. consist of lungs, but the *bronchi* do not divide equally into pairs as in mammals. A *larynx* or organ of voice is developed. The lungs of snakes are long and rudimentary, and exhibit little or no cellular structure in their posterior moiety. Only one lung is well developed, the left frequently existing in a rudimentary condition. The most perfect lungs found in R. are those of *Crocodylians* and *Chelonians*. The *brain* of R. is well developed and fills the cranial cavity. The *cerebellum* in *Crocodylia* has a 'distinct Vennus with transverse figures.' The *optic lobes* of R. are placed together on the upper surface of the mid-brain, and the *olfactory lobes* are usually long. The *sympathetic system* of serpents is not well developed. The *senses* of R. are well developed as a rule. The *eyes* are rudimentary in some lizards (e.g., blindworms) and in some serpents. In serpents the outer skin is continued to form the outer covering of the eye and is rendered transparent—hence the 'stony gaze' of the serpents, whose eyelids are in reality united. Many lizards, crocodiles, and chelonians have a 'third eyelid' or *nictitating membrane*. The crocodiles alone have an outer ear of small size, the *internal ear* being fairly developed in all R. The kidneys of R. open by their *ureters* into the *cloaca*. Distinct male and female generative organs are developed, but true copulatory organs are found only in the *Chelonians* and *Crocodylians*. The R. are *oviparous* animals—i.e., produce eggs from which the young are afterwards hatched. Some (e.g., vipers and some lizards) are *ovoviviparous* and retain the eggs within their bodies until the young are hatched.

Classification of Reptilia.—The R. are usually classified so as to form four orders of living R. and five orders of extinct forms. Former methods of arrangement divided this class into the *Saurian R.* (or those in which scales were developed as the body-covering), and *Loricata R.*, this latter group being represented by the *Crocodylia*, in which bony plates form part of the exoskeleton. The four orders of living R. are the (1) *Chelonii* (tortoises and turtles); (2) *Ophidia* (snakes); (3) *Lacertilia* (lizards); (4) *Crocodylia* (crocodiles). The extinct orders of R. include the orders (5) *Ichthyopterygia* (*Ichthyosaurus*); (6) *Sauropterygia* (*Plesiosaurus*); (7) *Dicynodontia* (*Dicynodon*) or *Anomodontia*; (8) *Pterosauria* (*Pterodactyls*); (9) *Deinosauria* (*Iguanodon*).

Republican, a name which has at different times been given to political parties of different shades in the United States of America. It was in the Convention of 1787 that parties first developed themselves. The 'Federalists,' among whom were Washington, Hamilton, the elder Adams, and Madison,

favoured a strong central government, not acting through the States, but directly upon the people. The 'Anti-Federalists' opposed any great central power, and maintained the rights of individual States. Jefferson was the head of this party, and, objecting to the name of 'Democrats,' with which it had been saddled, tried to introduce the name 'R.' In this he failed, and the title was gradually appropriated by the Federalist party. During the French wars, the Federalists sided with England, while the Democrats, under the presidency of Madison, who had by that time gone over to their party, declared war against England in 1812. In 1832 the two parties appear under the names of 'National Republicans' and 'Democratic Republicans,' but the former party soon after assumed the name of Whigs. About this time slavery became the burning question of national politics, and on it the parties were clearly divided. The Democrats denied the right of the central government to prohibit slavery in new States and territories, while the Whigs, who afterwards merged into the present R. party, affirmed and wished to exercise this right. Thus the Democrats became identified with the slavery party, the Republicans with the anti-slavery party. The former has always had its stronghold in the South, the latter in New England and the North. In 1861 the election of Abraham Lincoln, a R., to the Presidency, determined the secession of the Southern States. During the war, the R. party was for maintaining the Union at all hazards, while the Democrats of the North were for acquiescing in the Southern secession. After the war, the R. 'platform' became that of gradual 'reconstruction,' and of securing the complete political equality of the blacks and whites, the Democrats confining themselves to a defence of State rights, and to the promotion of a general amnesty for the rebellion. In 1868, the presidential election resulted in the return of the R. candidate, General Grant, who was re-elected in 1872. Again in 1876 a R., Mr. Rutherford B. Hayes, was elected to the Presidency. The present policy of the party may be defined as the support of a 'hard-money' currency, and of civil service reform.

Republics (Lat. *res publica*, 'common weal'), communities where the sovereignty is vested in the people, may be either democratic or aristocratic, i.e., all who enjoy civil may also enjoy political rights, or these may be restricted to a privileged order (see DEMOCRACY and OLIGARCHY). The purest and most ancient form of democracy was that in which all the citizens met in common assembly to enact their laws, a system practicable only in very small states, and which accordingly has been superseded in all the modern R. of the world by that of Representation (q. v.). Oligarchical Sparta, democratic Athens, and Rome, where the patrician privileges were gradually extended to the plebeians, constitute the great R. of antiquity; Venice, Genoa, and the Hanseatic Towns, of the Middle Ages. That of the United Netherlands (1609-1806) has passed away; so, too, the English Commonwealth (1649-60), and the still shorter-lived republic of Spain (1873). At the present day, with the exception of the tiny states Andorra and San Marino, France and Switzerland are the only European R., the former since 1870 (its two earlier R. of 1792 and 1848 having given place to the First and Second Empires), whilst the latter, whose independence was recognised in 1648, adopted (1847) a form of Federal Government (q. v.) resembling that of the United States. The Western hemisphere contains no fewer than eighteen R.—Argentina, Bolivia, Chili, Colombia, Costa Rica, Ecuador, Guatemala, Haiti, Honduras, Mexico, Nicaragua, Paraguay, Peru, San Domingo, the United States, Uruguay, and Venezuela. The empire of Brazil and the colonial possessions of European powers alone are governed on other than republican and democratic principles. See Freeman's *History of Federal Government* (1861), and *Comparative Politics* (1873); May's *Democracy in Europe* (1877); and Wolsey's *Political Science, or the State Theoretically and Practically Considered* (2 vols. 1878).

Repulsion is the action which two bodies exert upon one another when they tend to increase their mutual distance. Convenient though the idea may be of a repulsive force as far as the mathematical statement of dynamical truth is concerned, there is little doubt that in nature true R. as defined above has no existence. Force itself has no real existence, far less repulsive force. It is simply a convenient name for the rate at which the energy of a system is changing from one form to another. And when we speak of a system, we understand not only the portions

which are evident to us as matter, but also the medium which separate these, so that all radiation which takes place through this medium is as much a transformation of energy as a change of velocity or configuration in these more evident portions. The apparent R. between the earth and a balloon, as the latter ascends, is due to the fact that the balloon is lighter bulk for bulk than the air, *i.e.*, is attracted less by the earth. Similarly may many other apparent repulsions be explained; and there is every reason to believe that, as our knowledge of molecular physics advances, all R. shall be referred to attraction, and attraction to displacements in and through material media. Le Sage's theory of gravitation, and Maxwell's theory of electrical action, are steps in this direction.

Repute' is a technical term in Scotch law. See HABIT AND REPUTE. In English law it denotes an abatement. Thus, in speaking of the clear yearly value of an estate, after deducting rent charges or annuities, we say that it is so much a year, besides *reprises*.

Repute Ownership is a term of bankruptcy law, denoting the apparent ownership by the bankrupt, at the date of his bankruptcy, of goods belonging to another. The false credit given by R. O. has led to the general rule of law being that all goods so placed shall belong to the trustee for the creditors. An exception may occur when the nature of the goods is such as not to affect credit, or such as ought to have caused inquiry as to their ownership. Were an insolvent merchant to have a horse or plate belonging to another at the date of his bankruptcy, it is probable that the general rule would not hold good.

Reque'na, a town of Spain, province of Valencia, near the river Magro, in the midst of a beautiful, populous, and fertile plain, 53 miles W. of Valencia. Its inhabitants manufacture cottons, woollens, and silks. Pop. 10,500.

Re'quiem, a solemn mass for the dead celebrated in the Roman Catholic Church. The term is derived from the words 'requiem eternam dona eis' used in the service. The requiems of Mozart, Cherubini, &c., contain some of the most beautiful of sacred music.

Re'redos (Fr. 'behind the back') is most frequently used as an ecclesiastical term to denote the wall behind the altar. It usually takes the form of a highly ornamented screen.

Re'scripts, the official answers of a pope or emperor to questions in jurisprudence. If addressed to a corporate body, a rescript was termed a Pragmatic Sanction (q. v.).

Rescues (Fr., from Lat. *re*, and *cutere*, 'to shake off') and **Escapes** (from Fr. *échapper*, Ital. *scappare*, 'to skip away'). Rescue is the forcibly freeing another from arrest or imprisonment. It generally makes the rescuer an accomplice in the crime. To rescue, or attempt to do so, any one committed for murder, or on the way to execution, is a crime punishable with penal servitude for life. An escape of a person arrested upon criminal process is punishable by fine or imprisonment.

Resection (Lat. 'a cutting'), or **Excision** ('a cutting out') of **Joints**, is an operation in which the diseased bones of a joint are cut out in place of amputation of the whole limb. It is an operation of quite modern date, and one which could scarcely have been practised before the invention of anaesthesia. R. is performed chiefly on account of disease of the articular surfaces, or of the tissue of the bone excised, or on account of the growth of tumours from the bone, or as primary or secondary operations after injury. In the operation appropriate incisions are made, according to the nature of the parts to be removed; the soft parts are turned aside without injuring the main vessels and nerves, the joint is dis severed from its connections, and the whole of the morbid tissues are removed. The operation must be so performed as to make provision for the subsequent stability or mobility of the limb, as may be required. When the elbow-joint is the part to be removed, it is necessary that the mobility of the joint should be maintained, but in the case of the knee-joint an ankylosed joint is preferable. Within recent years Ollier and Langenbeck have pointed out the advantages of preserving the periosteum in subperiosteal excision, and in some cases this mode is of decided

advantage. R. was first performed in 1762, but it was not till 1850 that it was accepted as a justifiable mode of operation, chiefly through the influence of Professor Fergusson. The object of the operation is, by removal of the dead parts, to leave a more or less useful limb, although shortened. R. constitutes one of the triumphs of modern surgery. The operation may be performed on the shoulder-joint, the scapula, the clavicle, the elbow, the wrist, the hip, the knee, the ankle, the os calcis, the astragalus, and various parts of the foot.

Reseda'ceæ is a small natural order (6 genera, 20 species) of thalamifloral dicotyledons, consisting of annual or perennial herbs or rarely shrubs, occurring through Europe, in W. Asia, and in N. and S. Africa, but not in the New World. The flowers are irregular, small, and greenish; stamens indefinite; ovary one-celled, of two to six carpels, at length open at the top; seeds exalbuminous; leaves alternate. Most of the species are mere weeds, and excepting that *Reseda odorata* (Mignonette, q. v.) is among the most fragrant of plants, and *R. luteola* yields a yellow dye (see WELD), any properties they may possess are unappreciated.

Reserva'tion, Men'tal is the act of withholding from a statement some word or clause necessary to convey the real meaning of the speaker. An equivocal statement, while it conveys one meaning to the hearer, may, without alteration, be construed in another sense by the speaker. But that a statement involving a mental reservation be reconciled with the speaker's meaning, it is necessary that it be amplified. The moral legality of mental reservation has always been a moot point in theological casuistry. Pascal dealt largely with it in his attacks on the Jesuits. See Murray's *Theological Essays*, iv. 774.

Reserve'. This word is used in military language in two senses. Thus it is applied to a R. of troops held in readiness on the field of battle out of sight of the enemy for the support or reinforcement of the forces in action. Upon the proper use of reserves the fate of a battle has often turned. According to Jomini, they should be of the best quality of troops, but this opinion is now open to doubt, as the modern use of arms of precision make well-armed troops of any description powerful reserves. The R. *ammunition* of a British army is carried in carts, three going to a regiment of infantry and one to a regiment of cavalry. It is kept in the rear, and used to replenish the supply carried by the men when that is exhausted. When an army marches over rough and mountainous ground, the R. *ammunition* should be conveyed in pack-carriages.

In the second sense, reserves are bodies of men following ordinary civilian occupations, who may be called on to strengthen the regular standing army of a nation on an emergency. In all European states service is more or less compulsory, and the reserves thus practically come to be the active manhood of the country. These are usually divided into reserves of the active and reserves of the territorial forces. In Great Britain the R. consists of the auxiliary forces (the Militia, q. v., Yeomanry, q. v., and Volunteers, q. v.), the *Army R.*, and the *Militia R.* The *Army R.* was a force brought into organisation by Lord Cardwell's scheme of 1870. The first class of the *Army R.* consists of all short-service men who have not completed the term of service for which they enlisted, although they have been permitted to retire on serving a certain number of years with their regiments. A soldier who enters for short service must serve at least three (usually six) years with the colours, and the difference between that period and the term of twelve years in the R. Soldiers also who have served twelve years, provided their ages do not exceed thirty-four, may enter the R. They receive 4d. per day and an annual allowance of £1, besides 2s. or 2s. 6d. a day during their annual training of twelve days, and on occasion of 'imminent national danger, or great national emergency' may be called on to join the regular army. The first class of the *Army R.* came practically into existence for the first time in 1876. Its numbers in 1878 were 12,000 men and an ultimate limit of about 60,000 men may, under present circumstances, be looked for in the course of five or six years. A second class of the *Army R.* (about 15,000 in number) consists of pensioners, who are only liable for service in the United Kingdom. The *Militia R.* is a body of men consisting of not more than one-fourth of the total militia force who are liable for service in the army in the same manner as the first class *Army*

R. They receive £1 annual retaining fee, and are called out for fifty-six days training every year. In 1878 the number of the Militia R. who had gone through two annual trainings in addition to the required preliminary drill was estimated at 30,000 men, of whom 26,000 were looked upon as available.

Grave doubts, frequently expressed, as to whether the army and militia forces were a real or paper force, were set at rest by the complete success attending their being called out for the first time in 1878. In the course of two or three weeks 35,000 able-bodied soldiers out of about 38,000 men on the lists were incorporated in the regular army. The manner in which many of them at the call of duty gave up home ties and permanent and comfortable situations is a matter of justifiable national pride.

When the R. forces are undergoing their annual training they are under command of the officers of the regular forces of the district. The commander-in-chief's orders are conveyed to them through the Inspector-General of R. Forces. For the Navy see NAVAL RESERVE.

Reserve, in life assurance, is the sum set apart by a life assurance office to meet its liabilities. By the Life Assurance Act of 1870, an office must value its risks at least once in five years, when the R. required for each policy on its books is ascertained. The R. is the difference between the value of the reversions and the value of the future premiums, less the value of a portion of the premiums set apart for profits, expenses of management, &c. The table by which most life assurance companies now value their liabilities is based upon the Institute of Actuaries' experience of healthy male lives—the II. M. Table—and the rate of interest adopted is usually 4 or $\frac{3}{4}$ per cent.

Reserved List of naval officers is a class under which old and deserving officers are promoted to a higher grade, and placed upon half-pay, with only a very remote liability to be called upon for active service. It is regulated by Her Majesty's Orders in Council of June 25, 1851, December 29, 1853, August 1, 1860, and July 9, 1864. According to the Navy Estimates for 1877-78, 180 officers were upon this list, and their pay amounted to £44,133. They included 41 admirals, 15 vice-admirals, and 44 commanders, at from £2, 2s. to £1, 5s. per day, and 80 staff-commanders and navigating lieutenants at from 15s. 6d. to 5s. per day.

Reservoir (Fr.), a pond or basin for the collection and storage of water for the use of the inhabitants of a town, for irrigation, the supply of a canal or mill-dam, or for any other purpose. There are few districts so favoured by nature that it becomes unnecessary to store up the rainfall to meet one or other of the above wants. The construction of reservoirs dates from a remote period, for the system of impounding water for purposes of irrigation was practised in Egypt, Assyria, and India. Herodotus states that the great lake of Moeris was artificially formed to receive the overflow waters of the Nile; Nebuchadnezzar constructed an immense R. (140 miles in circumference) at Sippara; and in India and Ceylon there are numerous ancient tanks, formed by throwing a *bund* or embankment across a ravine or valley. Many thousands of these tanks are still in use in the Madras Presidency, and many others are ruinous from neglect; some of the latter are of immense size—one, the Ponari tank, having an area of 80 square miles. The construction of a R. calls for the greatest engineering skill. The best position for a storage R. is in an elevated gorge or valley, across which an embankment may be thrown, as in the case of the Indian tanks already alluded to. In determining the capacity of the R., the average annual rainfall and the annual service demand must be taken into consideration, as well as the probable loss by absorption and evaporation. As a rule, in England the capacity should be sufficient for 120 to 180 days' supply. An extensive drainage area should rise above the R., which itself should be sufficiently elevated to ensure the water, at its lowest level, being delivered at the highest point of the service pipes. In fixing the site, the impermeability of the rock forming the sides and bottom must be ascertained, otherwise leakage of the water might endanger the stability of the embankment. When the bottom is permeable, borings ought to be made to determine at what depth an impervious rock lies, and on it the puddle wall should rest. A R. should always be deep, so as to prevent the growth of vegetation. Before constructing the embankment, the suitability

of a site for it should be tested by trial shafts and other means. The foundation should be solid, and free of faults or fissures communicating with permeable strata beneath. All soft, loose, or porous materials should be excavated. The embankment may be formed of earth, and through its length, in the centre or nearer the water-side, an impenetrable wall of well-puddled clay should run. The slopes of the embankment are usually 3 to 1 on the inside and 2 $\frac{1}{2}$ or 2 to 1 on the outside. The water-side is commonly 'pitched' with stone, and the reverse sown with rye-grass or clover seeds. The outlet from the R. is by a culvert under the embankment, or better by a tunnel driven round the end of the embankment through solid ground. When the latter plan is adopted, a valve-shaft is constructed in a line with the puddle trench from the surface of the ground to the tunnel, which at this point is stopped with water-tight masonry in which two valved outlet pipes are placed. A waste-weir or waste-pit to carry away overflow occasioned by flood waters flowing into the R. is essential to its safety.

The water is usually conveyed from the storage R. to a *distributing* or *service* R., a large tank roofed over, and from it the supply is distributed for public use. It serves to check waste, for while the supply is constant, the consumption is variable, being less during night than day. The capacity of the distributing R. should be great, and its position high enough to command the highest dwelling to be supplied. When dwellings rise higher than it, these are supplied by a branch-pipe connected with the main from the storage R. *Compensation* reservoirs are constructed for the supply of streams, &c., in dry seasons, in order to compensate mill-owners and others for the water diverted from the watercourses on which the mills are situated.

Reshd, the capital of the province of Gililan, Persia, and one of the chief entrepôts for the Caspian, situated about 2 miles inland from the shallow Bay of Enzeli, amid groves and orchards, 150 miles N.W. of Teheran. It has a royal palace, and extensive caravanserais and bazaars, and carries on through its port of Enzeli a considerable trade with Russia, exchanging silks for iron wares. The road to the port is in the most wretched state at all seasons. Pop. 23,500.

Residuary Legatee. The person is so called in law to whom a testator bequeaths the remainder of his personal estate, after payment of debts and special legacies. If these exhaust the personal estate, the R. L. gets nothing.

Resignation, a Scotch law term denoting the form by which a vassal returns the fee (see FEE and LIFERENT) into the hands of the superior.

Resina (probably the *Retina* of Pliny), a town of S. Italy, province of Naples, at the foot of Mount Vesuvius, 6 miles S.E. of the city of Naples. It stands upon the site of the ancient Herculaneum (q. v.), the entrance to the excavations of which is a quarter of a mile distant from the royal palace of La Favorita in the immediate vicinity. R. is the starting-point for the ascent of Vesuvius, and furnishes travellers with guides, horses, and asses. From the slopes of the mountain the well-known wine *Lacryma Christi* is produced, and there is also considerable silk-spinning. Pop. (1874) 12,175.

Resins (from Lat. *resina*, connected with the Greek *rhēō*, 'I flow') constitute a class of vegetable secretions which are in their nature closely allied to the essential oils, being, according to the views of Liebig, oxidised forms of these bodies; and through the oleo-R. the one series passes gradually into the other. R. are solid bodies, more or less transparent, mostly breaking with a glassy fracture, entirely insoluble in water, but soluble in ether and the volatile oils, partially soluble in alcohol and the fixed oils, dissolving under the influence of heat. Dissolved in alcohol, R. form spiri' varnishes, while with oil they form ordinary varnishes such as copal varnish. They are all highly inflammable, and burn with a yellow smoky flame. Chemically, they are complex bodies, being in all cases combinations of several distinct resinous principles, though in ultimate composition they resolve themselves into pure hydrocarbons or compounds of carbon, oxygen, and hydrogen. R. from a commercial point of view may be separated into two distinct classes—hard and soft R. The former, the type of which is copal, comprehend the ordinary varnish R., and are distinguished by dissolving with readiness in common turpentine, the resulting compound forming a clear tenacious fluid. The more

valuable kinds are distinguished by their hard, glassy appearance, perfect transparency, and an almost entire absence of colour. The leading R. which come under this class are the dammars, copals, and animes; and under these heads several botanically distinct products are found in commerce. White dammar or piney varnish is obtained in India from *Valeria indica*, and allied R. are obtained in Oriental regions from various other species of *Vateria* *Vatica*, *Shorea*, and *Hopea*. A fine dammar is yielded by *Dammara orientalis*, and the well-known Kauria gum of New Zealand, the fossilised produce of *Dammara Australis*, is also a dammar resin. Copals or anime R. are obtained from species of *Hymenaea*, chiefly from the Zanzibar coast, but also from the W. coast of Africa, and from Madagascar, and a similar product is yielded by allied trees in Brazil. Another copalline resin is mastic. Thus, frankincense and sandarach are resinous exudations from pine trees, and sometimes classed as concrete turpentine. The Elemi or soft R. form a link between the copals and the oleo-R., being soft and clammy to the touch, often with a strong balsamic odour. They are in most instances to a large extent, sometimes entirely, soluble in spirit. They include Tacamahac of both the W. and the E. Indies; Mexican Elemi from a species of *Elaphrium*; and E. Indian Elemi, the produce of various species of *Canarium*. The elemi R. are used almost exclusively in medicine, and are not available for varnish making. A great variety of resinous substances are produced in various regions which are little or not at all met with in commerce; and of many of the substances extensively employed, very little is known with accuracy and certainty. Details regarding most of the substances alluded to here will be found under their own proper headings.

Medicinally.—Resin forms an important ingredient in ointments, but is not used internally. It is contained in charta epispastica, emplastra, and unguentum terebenthine. The preparations are *emplastrum resinae*, used chiefly for strapping wounds and ulcers; and *unguentum resinae*, employed as a stimulating dressing for indolent ulcers. *Resina jalapa* is given internally in doses of from 2 to 5 grains, and *resina podophylli* in doses of from $\frac{1}{4}$ to $\frac{1}{2}$ grain. See JALAP and PODOPHYLLUM.

Res Judicata, in law denotes a legal point on which judgment has been given by a supreme court as between two parties. The plea of R. J., if sustained, prevents either party from reopening the question already disposed of.

Resolution, in music, is following a discord by the combination which the ear requires in order to leave a satisfactory effect. It is usually effected by the dissonant note descending or ascending a degree, most frequently the former. Sometimes this is done in the next chord, while at other times it is deferred, or even interrupted by an intermediate progression.

Resolution of Forces. See COMPOSITION AND RESOLUTION OF VELOCITIES AND FORCES.

Resorcin is a colourless crystalline compound obtained by fusing galbanum with potassium hydrate, dissolving the fused product in water, neutralising with sulphuric acid, and mixing the clear filtered solution with ether. The R. is taken up by the ether, which is afterwards driven off by distillation. R. acted on by sulphuric acid yields a fine purple red colouring matter, which, with several other dyes derived from R., is used in dyeing and calico-printing. R. is closely allied to orcin, and its composition is represented by the formula $C_6H_4O_2$.

Respectant, or **Respecting**, an epithet applied in heraldry to two animals (not of prey) rampant face to face. Beasts of prey so placed are *rampant combattant*.

Respiration, the function of breathing. This function is one devoted to the purification of the blood by the excretion or elimination of waste matters, and to the absorption of oxygen gas. R. is thus not merely excretory; it is also nutritive, as the absorption of oxygen gas largely contributes to the maintenance of the animal organism. R. is essentially the same in animals and in plants, and consists in the absorption of oxygen for the vital purposes and chemical reactions of the living being. Oxygen gas is absorbed by plants for the purpose of decomposing certain of the substances of the plants. In this action the oxygen deprives such substances of part of their carbon and is ultimately given off in the form of carbon dioxide or carbonic acid (CO_2). This process would appear to be continually performed within living plant-cells. The presence and decomposing action of oxygen would appear to be thus neces-

sary for the life of the protoplasm of the cells. Plants placed amidst pure carbon die of suffocation like animals. Some flowers produce a relatively large quantity of carbonic acid through the absorption of oxygen, and a considerable increase of temperature takes place in such plants, as the result of the union of the oxygen with the carbon of the plant. Thus during the fertilisation of some species of *Aroides*, the temperature increases by 10° C.

In animals the respiratory organs vary in form and nature. In the lowest animals the general tissues of the body may serve as unspecialised breathing organs, just as in animals of tolerably high grade (e.g., earthworms), the general surface of the body may constitute the chief respiratory organ. The essential features of any breathing organ is a thin membrane, having the blood on the one side and the atmosphere (or water containing air) on the other. An interchange of products takes place between the blood and atmosphere through the membrane, oxygen passing into the blood and carbonic acid, &c., being excreted. The differences between the various kinds of breathing organs are really referable to variations in this arrangement. In man the breathing-organs consist of two lungs

Vertical Transverse Section of Chest, to show arched form of diaphragm, a a: the heart, b: lungs, c c: stomach, e: liver, d.

placed in the chest or thorax,—a cavity completely separated from that of the abdomen by the muscular partition named the *diaphragm* or *midriff*. The lungs of man and all quadrupeds are closed sacs, and do not open into air-sacs as is the case in birds. The lungs are two bodies of light spongy texture, and of a pink or light-red colour in infancy, but becoming dark-coloured in the adult, owing to the absorption of foreign carbonaceous matter from without. Each lung is merely the seat of the exchange between the blood and air already mentioned; and each organ may be simply described as a bag of *air-cells*. The lungs communicate with the outer world by means of the *trachea* or windpipe. At the upper part of this tube is the *larynx* or organ of voice; the trachea itself is a fibrous tube strengthened by imperfect rings of cartilage, which contribute towards the flexibility of the structure. The trachea divides at the root of the neck into two main branches or *bronchi*—one for each lung. Each bronchus on entering its lung divides and subdivides into a large number of branches, and thus constitutes 'a respiratory tree' of considerable extent. Traced to their ultimate terminations, the *bronchial tubes* are found to end in the *air-cells* of the lung. These cells are aggregated in groups, called the *lobules* of the lung. The air-cells vary in diameter from the $\frac{1}{16}$ th to the $\frac{1}{8}$ th of an inch. Their walls are formed of fibrous and elastic tissues, and are lined by *squamous* or *tessellated epithelium*. Thus the air received through the *trachea* or windpipe permeates every part of the lung-structure, and is at last received into the air-cells of which the lungs are essentially composed. External to the air-cells of the lung, and forming a

Two Air-Cells (b), with the ultimate bronchial tube (a) which opens into them (magnified 20 diameters).

dense network thereupon, are the *capillary blood-vessels* of the lung. The capillary network is most dense in the centre of the

Air-Cells, with capillary blood-vessels injected.

The *trachea* or 'windpipe' extends from the fifth cervical vertebra to the third dorsal vertebra, and measures from 4 to 4½ inches in length, and ½ths of an inch in diameter. Its incomplete cartilaginous rings number from sixteen to twenty. The windpipe is lined by *ciliated epithelial cells*, and unstriated muscular fibres also occur. The branches of the windpipe (*bronchi* and *bronchial tubes*) at first resemble the windpipe; but as they gradually become smaller they lose their cartilaginous rings, the walls of the smallest air-tubes being chiefly composed of fibrous tissue, along with a muscular investment. The *right lung* is larger than its neighbour, and is divided into three lobes; the *left lung*, which is longer and narrower than the right, having only two lobes. Each presents when anatomically examined a *base* or lower part resting on the *diaphragm* or 'midriff'; an *apex*, extending into the root of the neck; an *external surface*, smooth and convex; an *internal surface*, concave in form; a *posterior border*, rounded and broad; and an *anterior border*, thin, sharp, and overlapping the *pericardium* or sac in which the heart is contained. The *root of the lung* exists about the middle of the inner surface of each lung. At this point the blood-vessels, nerves, and lymphatics enter the lung, the chief blood-vessels being arranged so that the *pulmonary veins* lie to the front, the pulmonary artery in the middle, and the *bronchi* and blood-vessels of the lung behind. The average weight of the two lungs is 42 oz., the right lung weighing about 2 oz. heavier than the left. Those of the male are heavier than those of the female, and weigh in the proportion of 1 to 37. In the female the relative weight is as 1 to 43. The *pulmonary artery* arising from the right ventricle of the heart carries venous blood into the lungs, and spreads out in the organ to form part of the dense capillary network already mentioned. The capillaries of the lung in due time unite to form the *pulmonary veins*, which convey the purified blood from the lung back to the left side of the heart for redistribution through the body. Besides these vessels which serve to convey blood *through the lungs*, these organs have blood-vessels (*bronchial arteries and veins*) for their inherent nutrition. The lungs are also supplied with *Lymphatics* (q. v.), and the *nerves* of the lung arise from the *pulmonary plexus* (*anterior* and *posterior*), formed chiefly of branches of the pneumogastric and sympathetic nerves.

The brief study of the mechanism and details of the process of R. may be prefaced by a few observations on the *chemical composition of the atmosphere*. Ordinary atmospheric air consists of two gases—*oxygen* and *nitrogen*, mixed in the proportions of 21 to 79 in 100 parts. The oxygen is the important element, the nitrogen being chiefly useful as a diluent, and bearing no active share in the work of R. These are the essential gases of the atmosphere, but in addition varying quantities of other substances occur therein. Thus in ordinary air traces of carbonic acid (4 or 5 vols. of CO₂ to 10,000 of air) are to be met with; and watery vapour is usually present to the extent of 1.40 per cent. Traces of ammonia and other substances are also found. The quantity of carbonic acid may be vastly increased under certain circumstances, as, for example (according to Dr. Angus Smith), in the dress-circle of a theatre at 11.30 P.M., where it attained a percentage of .0757; or in a Cornish mine, where the quantity was 2.5000 per cent. It may now be asked, what changes happen to the air during R.? The chief are as follows:—(1) That the air expired from the lungs is *warmer* than the surrounding atmosphere, and attains a temperature varying from 97° to 99½°.

The expired air literally exhibits the temperature of the blood. (2) The *carbonic acid* is increased. About 4½ per cent. of oxygen is abstracted from every volume of air taken into the lungs, a rather smaller amount of carbonic acid being supplied from the lungs in place of the oxygen. About 1346 cubic inches (636 grains) of carbonic acid is given out of the lungs in one hour; and estimated by weight, the carbon exhaled from the lungs per hour amounts to 173 grains, making about 8 oz. of pure carbon in twenty-four hours. The quantity of carbonic acid emitted in R. from the lungs varies according to the circumstances of the individual. Thus the quantity increases from eight to thirty years of age, and diminishes from forty to old age; the higher the temperature, the less carbonic acid is excreted; in spring more carbonic acid is given off when the air is moist, and more is exhaled than in any other season; more carbonic acid is exhaled during the day (relatively to the oxygen absorbed) than during the night; after food the quantity of carbonic acid exhaled is increased; exercise in moderation increases its amount, and during sleep there is a diminution in the quantity of the gas exhaled. (3) The *oxygen* is diminished in R. The quantity of oxygen absorbed per hour is 1584 cubic inches (= 542 grains). Thus more oxygen is absorbed than is exhaled along with the carbon to form carbonic acid without alteration of volume, the loss of oxygen being due to absorption. (4) *Watery vapour* is added to the atmosphere in R. The quantity of watery vapour given off from the lungs is sufficient to saturate the atmosphere. About 9 or 10 ounces is a fair average estimate of the amount of water exhaled from the lungs in twenty-four hours. (5) That *ammonia* is given off during R. is proved by the researches of Reade and others, but its amount is very small; and (6) *organic matters* are added to the atmosphere; about 3 grains being estimated to be exhaled from the lungs in twenty-four hours.

The changes which occur to the blood in R. are equally important. The blood sent to the lungs through the preliminary artery and its branches from the right side of the heart is *venous* or impure, and is therefore dark coloured. After passing through the lungs the *venous blood becomes light coloured*—a change due to the absorption of oxygen gas, which is chemically combined with the *hemoglobin*, or colouring matter of the blood corpuscles. Thus the great result of the passage of the blood through the lungs is a loss of carbonic acid and a gain of oxygen. The blood also becomes 1° to 2° F. warmer after passing through the lungs, and also appears to coagulate or clot more readily and firmly than before. Thus a fair comparison might be made between the lungs and their work in R. and a market-place or exchange. The blood offers to the air certain waste products (*viz.*, carbonic acid, heat, water, ammonia, and organic matters), and obtains from the air oxygen and nitrogen, of which the former is by far the more important. The *essential and intimate part* of the respiratory act is accomplished in virtue of the 'law of diffusion of gases,' the oxygen passing inwards to the blood through the thin capillary-walls and through the walls of the air-cells of the lung; while the carbonic acid and other matters pass outwards from the blood into the air-cells, and are thence exhaled in the act of expiration. They are literally *waste products*, which represent the 'wear and tear' of the living machine, gathered from all parts of the body by the blood, and thus brought to the lungs to be excreted. A certain share of the waste matters falls to be excreted by the *kidneys*, *skin*, and *liver*, which thus bear a very definite relation to the lungs as organs of excretion. The lungs thus excrete most carbonic acid (about 15,000 grains in twenty-four hours), the skin in the same period excretes from ½th to 1½th of the quantity exhaled from the lungs; while the kidneys also excrete a small quantity of this gas. In diseases of the lungs the skin and kidneys excrete much larger proportions of carbonic acid; the normal function of the skin being to eliminate water and solid matters (11,500 grains water; solids 250 grains in twenty-four hours); while the kidneys excrete a much larger quantity of water (23,000 grains in twenty-four hours) along with organic matters (680 grains) and mineral and saline matters (420 grains).

The nature of the *respiratory movements* may be readily understood. Two acts (*inspiration* and *expiration*) are involved in this process. The former is by far the more forcible and important. It is essentially a muscular act. The chest or thorax itself is a movable framework or cage, the cavity of which is capable of being enlarged in various directions. All that is required to

effect inspiration (bearing in mind the elasticity of the lungs) is the increase of the capacity of the chest, through the alteration of its floor and sides. By such alteration or measure of capacity the pressure of air in the lungs is diminished, and an additional quantity enters the lungs to equalise the pressure on both surfaces (internal and external) of the chest. The chest is enlarged, firstly, in a *vertical* direction by the contraction of the *diaphragm* or *midriff*, the great muscle forming the floor of that cavity. The sides of the diaphragm descend to the greatest degree, while its central tendon remains firm, and thus the thorax is pulled downwards, its sides being also pulled outwards below. Secondly, the chest is enlarged from side to side (*laterally*), and from before backwards (in the *antero-posterior* diameter), by the ribs being elevated in front and at the sides. The breastbone is also pushed upwards and forwards. The agents which accomplish these movements of the ribs and breastbone in ordinary breathings are the various *intercostal muscles*, or those extending from one rib to another. But in forced breathing, other muscles (such as the *scalene* muscles, the *serratus magnus*, the *pectoral* muscles, &c.) are also called upon to assist the intercostals. The cavity of the chest being thus enlarged, the lungs are allowed to expand, and air is duly inhaled. The act of *expiration* is effected chiefly by the elasticity of the lungs and chest. Both are forced from their normal position, as it were, in inspiration; and both return in expiration to a position of rest. The movements of breathing vary in the sexes. The breathing of men is termed *abdominal*, since the movements of the abdominal walls are more clearly marked than in women, in whom the chest appears to participate more exclusively in these motions. Hence in females the breathing is said to be *pectoral*. In young children the diaphragm is the chief agent in the movements of breathing.

The *total quantity of air* which passes into and out of the lungs of an adult in twenty-four hours in ordinary tranquil breathing is about 686,000 cubic inches. The average quantity exchanged at each breath in the adult man is about 30 or 35 cubic inches. A hard-working labourer would breathe in twenty-four hours 1,568,390 cubic inches of air. The most violent expiratory act does not empty the lungs of air. Hence the quantity (about 100 cubic inches on an average) which remains in the lungs after the deepest expiration is named *residual air*. The quantity (30 to 35 cubic inches) which passes into and out of the lungs in ordinary breathing is named *tidal air*. The quantity over and above the *tidal air* (varying in different individuals) which may be inhaled by a deep inspiration is called *complemental air*; that expelled by a deep expiration (over and above the *tidal air*) is named *reserve* or *supplemental air*. The chest or thorax is lined by a delicate membrane named the *Pleura* (q. v.). The *work of the muscles engaged in R.* has been calculated by Professor Houghton to amount to 21 foot-tons in twenty-four hours.

The *Hygiene* of the present subject is all-important. Upon the due understanding of what R. is, and upon a knowledge of the processes whereby the effete or vitiated air may be got rid of, and a due supply of fresh air introduced into our dwelling-places, the health of families and communities may be said largely to depend. The breath re-breathed is unquestionably the source of very many serious disorders, not merely personal but also epidemic. The breathing of an atmosphere in which the quantity of organic matter and carbonic acid is increased above the normal standard is fraught with serious, or it may be fatal, effects to man and the higher animals generally. The headaches, drowsiness, and lassitude felt in places of public entertainment and in churches and halls are due simply to imperfect oxygenation of the blood in a vitiated atmosphere; and the imperfect ventilation of our sleeping apartments causes restless nights, and destroys the beneficial effects of sleep. That the animal body may tolerate a vitiated atmosphere in which it has been placed for some time, and thus unconsciously injure itself, is proved by the experiment of introducing a sparrow into a bell-glass in which another sparrow has been confined for two hours. The sparrow thus introduced into the atmosphere vitiated by the first bird, is found to perish instantly, and this although the first bird could have remained under the bell-glass for another hour without endangering its life. The deaths of infants aged from one to fifteen days in the Dublin Lying-in Hospital numbered 2994 (out of 7650 births) in four years, during a certain period; while after the introduction of a new and better system of ventilation, the death-rate sank to 279 deaths during another period of four years with equally

numerous births. More than 2500 deaths (or 1 in 3) were thus caused by imperfect ventilation.

Diseases of Organs of R.—The structures which are mainly affected in disease of the lungs are—(1) the bronchial tubes, (2) the pulmonary air-cells, vesicular structure or parenchyma of the lungs, and (3) the membranes covering the parenchymatous part, forming that portion of the serous sac between the lungs and the walls of the thorax. That portion of the sac immediately investing the lungs is called the *pulmonary pleura*, while that investing the parietes of the thorax is called the *parietal* or *costal pleura*. One or more of these pulmonary structures may be the seat of inflammation (q. v.). When the *bronchial* is inflamed, the disease is called *Bronchitis* (q. v.); when the *substance proper*, or parenchyma, is inflamed, the disease is termed *Pneumonia* (q. v.); and when the *pleura* is inflamed, the affection is described as *Pleuritis* (q. v.). It is seldom that these morbid states are completely isolated, but the disease is usually named according to the more prominent symptoms. When inflammation of the substance of the lung, or pneumonia, is associated with inflammation of the air-tubes, or bronchitis, the disease is termed *broncho-pneumonia*; and when associated with inflammation of the investing pleura, or pleuritis, it is termed *Pleuro-pneumonia* (q. v.). These diseases frequently give rise to secondary diseases which are more persistent than the primary, such as *Hydrothorax* (q. v.), or an effusion of serum into the cavity of the chest; *Pneumothorax* (q. v.), or a collection of air or gas, in the cavity of the pleura, generally co-existing with fluid in the same cavity, and called *hydro-pneumothorax*; *Emphysema* (q. v.), or enlargement of the air-cells by dilatation, attended with obliteration of the blood-vessels distributed over their walls, forming a most serious complication of bronchitis; *Empyema* (q. v.), or an accumulation of pus in the cavity of the chest. *Pulmonary tuberculosis*, or *Phthisis* (q. v.), the growth or exudation of tubercles, which undergo various changes in the lungs, is the local manifestation in the lungs of the constitutional phenomena of tuberculosis. The lungs are also liable to lesions due to the syphilitic poison, affecting the mucous membrane of the bronchial tubes; or gummatous nodules may be developed in the pulmonary substance, or they may be associated with miliary tubercles in the lungs. Syphilis (q. v.) undoubtedly exerts a powerful influence in the development of phthisis. *Gangrene* of the lungs, the disintegration and breaking up into fragments of the fibrous tissue of the lungs, is comparatively rare, and almost invariably fatal. *Hæmoptysis* (q. v.), or the spitting of blood from pulmonary hæmorrhage, may depend upon a variety of causes of more or less serious import, and in some cases it is the result of cardiac disease, and occasionally it is a form of vicarious menstruation. See *Principles and Practice of Physic*, by Sir Thomas Watson (Lond. 1871); *Diseases of the Chest*, by Dr. Waters (Lond. 1873); and *Phthisis*, by Dr. A. Flint (Lond. 1875).

Respiration, Artificial, is required in all cases of suspended animation, as in some cases of childbirth, drowning, the inhalation of chloroform, noxious gases, &c. The operation for producing it may be performed in various ways. In the case of new-born infants, suspended animation is of frequent occurrence; but the stimulus afforded by exposure to the external air, conjoined with certain centric causes arising from deficient aeration of the blood, are generally sufficient to excite the respiratory muscles. Should respiration, however, not immediately follow, A. R. may be excited by blowing on the face, by a smart pat on the nates, or by dashing some drops of cold water on the face. Failing this, the infant should be plunged in a basin of warm water, and, as it is being removed from the bath, cold water should be dashed upon it. The tongue should be drawn forward, the mucus should be rapidly removed from the fauces as far as is possible, and A. R., by the methods hereafter described, should be persevered in so long as the slightest action of the heart continues. In such cases, the umbilical cord should not be tied until it has ceased to pulsate, as there is a possibility of a certain amount of placental respiration.

In cases of threatened asphyxia from chloroform and other anæsthetics, a condition indicated by lividity of the face or by laryngeal stertor, the tongue should be pulled well forward with a pair of forceps sufficiently far to open the larynx freely, that the patient may be enabled to breathe freely. On the first symptom of the failure of the pulse the chloroform must be with-

drawn, the breast should be well slapped with cold towels, and hot effusions applied to the head, and if the galvanic battery is at hand it should be applied.

A. R. may be performed by passing a pipe through the mouth, or a male catheter through the nostril, into the glottis; or by simply putting a pipe into one nostril, and closing the mouth and the other nostril, and blowing through it; or by using in a similar manner a small pair of bellows, the nozzle being inserted into the nostril. The air should be forced into the lung with very great gentleness, and the larynx should be pressed against the spine so that the air may not go down the oesophagus. If the larynx has been crushed by a rope, or by a violent blow, or obstructed mechanically, it may be necessary to perform Tracheotomy (q. v.), so as to impel a current of air directly into the trachea. At the same time the lungs may be filled with pure air by compressing the chest and abdomen, so as to expel the vitiated air, and then allowing them to recover their usual dimensions by the natural elasticity of their parietes. Dr. Marshall Hall has recommended that the patient be turned prone so that the tongue may hang forwards, the larynx thus be opened, and that respiration be then set up by gentle pressure along the back, and turning the patient on his side at regular intervals.

In the case of a person apparently drowned, or in an asphyxiated condition, the best mode of producing A. R. is that recommended by Dr. Marshall Hall and modified by Dr. Sylvester and others, as follows:—The patient is laid on his back on a plane, inclined a little from the feet upwards; the shoulders are gently raised by a firm cushion being placed under them; the tongue is brought forward so as to project a little from the side of the mouth. The operator then grasps the patient's arms just above the elbows, and raises them till they nearly meet above the head. This action imitates inspiration. The patient's arms are then turned down, and firmly pressed for a moment against the sides of the chest. A deep expiration is thus imitated; and these two sets of movements should be perseveringly continued at the rate of about fifteen times in a minute.

The *Report of the Scientific Committee on Suspended Animation*, presented in 1862 to the Royal Medical and Chirurgical Society of London; the *Instructions for the Restoration of the Apparently Dead from Drowning*, issued by the National Lifeboat Institution in 1864, and the *Report of the Scientific Committee on the Uses and Effects of Chloroform*, printed in 1864 in the *Proceedings of the Royal Medical and Chirurgical Society*, recommend the methods described above.

Respirator is the name given to an apparatus worn over the mouth to warm the cold external air before inhaling it into the lungs, or to enable a person to breathe in an atmosphere charged with dust or noxious vapours. Jeffrey's R., patented 1836, and designed for persons having weak lungs, consists essentially of several layers of very fine wire mounted on a light oval curved framework, which covers the mouth closely and is secured by bandages. In the act of respiration the air passes through the interstices of the fine lattice wirework, which is heated with every expiration of the warm breath, and the heat thus imparted to it serves in turn to warm the cold air when inhaled. By this arrangement invalids are enabled to enjoy open-air exercise in cold weather without discomfort, while there is no obstruction to speaking. Several other kinds of respirators have been contrived for the use of operatives exposed to dust of all kinds. For cutlers a R. of magnetic gauze which lays hold of the particles of metal has been designed. Another valuable invention is the smoke R. of Tyndall, which enables firemen to breathe freely for some minutes in a room filled with dense smoke. It consists of a brass cylinder containing a valve chamber and a filter tube. In the former, ball-valves regulate the entrance of the purer air and the discharge of expired air, and in the latter are several superimposed layers of dry cotton wool, fragments of lime, fragments of charcoal, and wool saturated with glycerine, all of which serve to remove the particles of carbon and other impurities from the atmosphere. The R. is shown in the cut attached to a mask.

Tyndall's Smoke Respirator.

When combined with a hood and spiral wire-tubing, it is adapted

for the use of miners entering an atmosphere charged with deadly gases.

Respondent is the legal designation of the party requiring to answer, in a petition presented against him, to a court of law.

Respondentia is the name of a kind of loan on the security of a ship's cargo. If the goods are lost, the creditor under a R. bond has no claim against the owner of the ship, consequently he usually stipulates for a high premium should the voyage be successful. When the *ship* is pledged in security of a loan, the legal instrument is called a bond of Bottomry (q. v.).

Responsibility for Crime. Certain classes of persons are, on account of age or infirmity, held to be incapable of committing crime. An *infant* (see AGE) under seven cannot be guilty of felony. Above seven, a measure of R. attaches; but there is a presumption in favour of innocence till fourteen, when the individual becomes fully responsible, unless fatuous or lunatic. An act which would otherwise be criminal may be excused or palliated by ignorance as to fact, but not by ignorance regarding law. See IGNORANCE OF THE LAW; CAPACITY, LEGAL; IDIOTS AND LUNATICS, LAW REGARDING.

Responsory, Response, or Respond', a versicle sung by the choir in answer to the priest, as in litanies, or a short anthem interpolated in the reading of a lesson.

Rest (in music), a sign that silence is to be observed for an indicated period. The following rests correspond to the principal notes:—

Breve.	Semi-breve	Minim.	Crotchet.	Quaver.	Semi-quaver.	Demisemi-quaver.	Semidemi-quaver.

Dots affixed to rests produce the same effect as with notes, a single dot adding one-half more, and two dots three-quarters more to the value; thus, $\text{F} \cdot$ equals three quavers, and $\text{F} \cdot \cdot$ seven semiquavers. There is no sign for a bar's rest, but a semibreve rest is frequently used to indicate it where a bar contains a semibreve or less, and a breve rest where it contains more than a semi- . The number of bars in rest are sometimes written above two lines Four bars.

crossing the staff obliquely, thus

Rest-Harrow (*Ononis*), a genus of about 60 species of leguminous herbs or small shrubs, often covered with viscid hairs, giving the plants a peculiar, goat-like odour. The leaves consist of three leaflets; the pink or yellow flowers have a broad standard, oblong wings, and an incurved keel; the calyx is five-cleft; the stamens monodelphous; the stigma terminal, and the pod thick. *O. arvensis* is a common British plant of dry pastures and sandy shores, and *O. spinosa* is locally plentiful in stiff clay land. The long and strong matted roots of the former, impeding or arresting the progress of the plough and harrow, has established the popular name of R.-H. The genus is confined to Europe, the adjoining parts of Asia, the basin of the Mediterranean, and the adjacent isles.

Restiaceæ, a natural order of monocotyledons allied to *Juncaceæ* and *Cyperaceæ*, is confined to the southern hemisphere, and found chiefly in S. Africa and Australia. The plants are rushy or reed-like, with very rigid wiry stems, simple narrow leaves, and spiked or capitate flowers, with generally separate sexes. The matted roots serve to bind shifting soil, and one of the species at the Cape (*Restia tetraura*) forms a most valuable thatching material, whilst the stems of others are made into brooms, baskets, &c.

Restigouche', a river of British America, separating for the last 50 miles of its course New Brunswick from Quebec. It flows N.E. into the Bay of Chaleur, has a length of 200 miles, and drains an area of 4000 sq. miles. It is navigable for 16 miles by the largest vessels.

Restitution, in law, means the restoring of goods lost or stolen to the owner. See FINDING GOODS, LAW REGARDING.

Restora'tion, in English history the event whereby, according to the Thanksgiving Office of the Church of England down to 1859, on May 29, 1660, 'our then most gracious Sovereign Lord, King Charles the Second, notwithstanding all the power and malice of his enemies, was restored to his own just and undoubted rights; and unto us also was restored the publick and free profession of the true religion and worship, together with our former peace and prosperity, to the great comfort and joy of our hearts.'

Restora'tionists are a sect of American Universalists. About 1818 a Universalist preacher, Hosea Ballow, began to teach that sin is entirely connected with the body, and that the soul is therefore freed from the punishment of sin when it is freed from the body by death. A sect holding this opinion separated from the general body of the Universalists in 1831, and assumed the name of 'Universal Restorationists.'

Resurrection of the Dead, as ordinarily understood, means not merely that when the body dies the soul rises to a new and a higher life, but that the bodies of men rise again. This doctrine was found under different forms in many of the ancient theologies—in that of the Stoics of Greece, the Parsees, and the Hindus. It also appears in the Jewish literature, connected with the ideas of the Jews regarding immortality. Their idea of this was very dim till after the Captivity, but always grew brighter as the hopes of a national restoration waned, and the belief in individual immortality superseded that in Israel's perpetual existence. Now, according to Jewish ideas of the relation between the soul and the body, immortality must necessarily be bodily. At death the spirit returns to God who gave it (Eccl. xii. 7), the *shade* only descends to Sheol, and if the person were to begin a new life the spirit must again be breathed into his shade (*cf.* Ezek. xxxvii.). The belief in a R., then, was prevalent in the 3d c. B.C., although not universally accepted (Dan. xii. 2; Eccl. iii. 21, xii. 7, xiv. 17, xvii. 22-28, &c.), as it was not even in the time of Christ (Mark xii. 18; Acts xxiii. 8). In the Pauline theology two new ideas are added to the old Jewish ones regarding the R.: first, that of a spiritual R. along with Christ, in consequence of the believer's mystical union with him by faith (see JUSTIFICATION and REGENERATION). The second had reference to the nature of the R.-body. Paul explicitly and repeatedly condemns the idea that people would rise again with the same bodies which they had in life (1 Cor. xv. 50; *cf.* Gal. i. 16; Eph. vi. 12). These bodies are to be metamorphosed, their perishable elements changed into imperishable (*v.* 42).

The R. of Christ is generally regarded as the fundamental truth of the gospel, and as the most important as well as the best authenticated fact in the history of the world. Heterodox writers, who reject it as a fact, adopt various theories to account for the belief regarding it which has prevailed among Christians from the first. Some have imagined that the reappearance of Jesus after his death was of the nature of an apparition (*cf.* Luke xxiv. 31, 36, 37, 51; John xx. 19, 26; Acts i. 9). Others suppose that he did not actually die, but merely swooned, and then revived after he was taken down from the cross. But no such theory can be framed which is not negatived by one or other of the evangelical accounts; *e.g.*, the first of the above by Luke (xxiv. 38-43), and the other by the inability of the disciples to recognise him (John xx. 15, xxi. 4-7; Luke xxiv. 16). The strongest and earliest literary proof of the doctrine is in the Epistles of Paul, especially 1 Cor. xv. 3-8. The strongest testimony of all is the traditional—namely, the fact that all the apostles and first disciples believed it—'held it with a conviction so absolute that it inspired them with a zeal and courage to live as missionaries and die as martyrs.' See Hodge's *Syst. Theol.* (Edinb. 1873); Reuss' *Hist. de la Theol. Chrétienne* (3d ed. Strasb. 1864); Greg's *Creed of Christendom* (3d ed. Lond. 1874); *Supernatural Religion*, vol. iii. (Lond. 1877), and replies by Professor Lightfoot in *Contemp. Review*.

Retain'er is in law the fee given by a solicitor to counsel to secure his services for a client. A *general R.*, for which five guineas is the usual fee, entitles the party who gives it to a preference in *specially* retaining the counsel to whom it is given. It is the duty, therefore, of the barrister who has received the general R., should a special one be offered by the other

party, to ascertain before accepting it if the giver of the first fee means to retain him specially. Should it be so, he is bound to the first client.

Retain'ing Wall is the name given to any wall built so as to retain earth, sand, or other yielding substance in forms which they could not naturally preserve. It must therefore be made sufficiently strong and solid to resist effectually the thrust of the material behind it. The necessary thickness depends very much upon the nature of the material which it is purposed to retain in position. A dry earth does not require such a strong R. W. as a moist earth. Hence the retaining walls of the banks of rivers or of walls of docks have a thickness equal to about one-half their height, while in other ordinary circumstances the thickness is just about one-third the height. In docks, too, other considerations, such as the erection of cranes and other machinery, must also be taken into account. To guard against the accumulation of water behind the R. W. small holes called 'weeping holes' are made in it. These are, of course, placed near the base.

Reten'tion, a term of Scotch law, denoting the right which one having movable property which he is bound to deliver to another has of withholding delivery until the debt has been paid. Thus, goods sold become the property of the purchaser, but the seller has a right of R. till the price be paid. See *HYPOTHEC*; Eng. law, *LIEN*.

Reten'tion of U'rine, in medicine, denotes the want of power to expel the urine from the bladder, and is to be distinguished from *suppression* of urine, a condition in which the urinary bladder is empty. R. of U. is merely a symptom, and as such may depend on various causes, such as mechanical obstructions and functional conditions.

The principal mechanical obstructions are—(1) Stricture of the Urethra (*q. v.*); (2) Enlargement of the prostate gland, especially in old men; (3) Tumours within the urethra; (4) Tumours pressing upon the urethra; (5) Foreign bodies in the urethra, as calculi, fragments of bougies introduced from without, clots of blood, mucus, &c.; and (6) Contraction of the urethra from external injury on the perinæum. R. of U., depending on such cases, can only be removed by surgical operations. The principal functional conditions are—(1) Spasms of the urethra, and (2) Paralysis of the bladder, and the atony which follows over-distension.

R. of U. from organic stricture is always more or less connected with spasm induced by irritation of the stricture; but in *spasmodic retention*, or *spasm of the urethra*, there is no perceptible change in the tissue of the urethra. The chief causes of spasmodic R. of the U. are gonorrhœa, excessive drinking, the use of cantharides or turpentine, prolonged voluntary R. of U., morbid conditions of the urine, and surgical operations about the pelvis. The obstruction usually occurs at the point where the membranous part of the urethra is surrounded by its muscles, and it may be overcome by the use of the catheter. Sir H. Thompson says that the Tinct. Ferri Perchloridi, in doses of 15 to 20 minims, administered four or six times, at intervals of a quarter of an hour, will relieve the spasm. In very severe cases, a full dose of Tinct. Opii should be given, and the patient should be kept in a hot bath till he is nearly faint; and, in some instances, it may be advantageous to administer anæsthetics. In R. of U. from paralysis, and from the atony which follows over-distension, the treatment consists in relieving the bladder by means of the catheter, and keeping the bladder constantly empty by retaining the catheter in the bladder.

R. of U., in children, is generally caused by impaction of a stone in the urethra, by abscess pressing on the urethra, by tumour of the bladder or urethra, or by a ligature round the penis. In men, stricture is the most common cause; but it may be from spasm, abscess, prostatitis, stone, &c. In the female sex, it is generally due to nervous causes, hysterical retention, or to pressure, as in parturition. See *BLADDER, KIDNEY, and URETHRA, DISEASES OF*.

Ret'ford, East, a market-town of England, Nottinghamshire, on the right bank of the Idle, a branch of the Trent, 33 miles N.N.E. of Nottingham by the Great Northern Railway. It has a parish church of St. Swithin, recently restored by Mr. Place; a townhall (1867) in Renaissance style, with a Mansard roof, from which rises a clock-tower 100 feet high; and an old

grammar-school (rebuilt 1858). R. sends supplies of butter, poultry, and eggs to Sheffield and other towns of Yorkshire. It has also paper and corn mills, and a trade in corn, malt, &c. Pop. (1871) 3194. The parliamentary borough, which returns two members, had a pop. in 1871 of 49,257.—**West R.**, on the left bank of the Idle, is a modern extension of the older town, with which it communicates by a handsome bridge of five arches.

Bethel, a town in the French department of Ardennes, on the right bank of the Aisne, 23 miles N.N.E. of Rheims by rail. It has manufactures of shawls, merinos, and other woollen fabrics, leather, &c. Pop. (1872) 7086.

Retina. See EYE.

Retirement in the British army is of two kinds, voluntary and compulsory. Officers may voluntarily retire on half-pay after 25 years' service, or on full pay according to a sum annually voted by Parliament. Compulsory retirement is now regulated by the Army Warrant of 1877. After the abolition of purchase promotion became much longer in attainment, as is shown by the following comparison of the average time taken in 1870 and 1875 for an officer to secure a given rank.

	Average time in 1870.	Average time in 1875.
To secure a Captaincy . . .	9 years	15 years 9 months
Majority . . .	18 years 11 months	29 " 3 "
" Lt.-colonelcy . . .	23 " 6 "	33 " 6 "

To meet this evil the Warrant was introduced. By it the establishment of general officers was cut down to 200. Colonels were not to be promoted after the age of 55; lieutenant-colonels were to be removed from their regiments on completing 5 years' service without promotion; majors after 7 years' service as majors, or 27 years in all; and captains after 7 years' service as captains, or 20 years' service in all. Lieutenant-colonels were also to retire on full pay on attaining the age of 60, unless their services were specially retained.

In the Navy, the ages of compulsory R., are as follows:—admirals and vice-admirals 65 years, rear-admirals, 60 years, captains 55 years, commanders 50 years, and lieutenants 45 years.

Retort, a vessel of great importance in a chemical laboratory, intended for distilling substances. It may be made of glass, earthenware, or metal. The glass R. is the most common, and consists of a flask-shaped vessel or *receiver*, the neck of which is drawn out in the form of a longer or shorter tube, and is so fixed in direction that it lies horizontal, or is even depressed. The vapour of the liquid which is being distilled is carried along this tube to the condenser (see DISTILLATION). Retorts are frequently provided with a stopper at the top, so that the substance may be introduced without dirtying the tubular neck.

Retreat (Fr. *retraite*), (1) A military operation, either forced or strategic, by which an army retires before an enemy. It is often a movement of much difficulty and delicacy, particularly when following a defeat. In such a case it is necessary that a strong rearguard, able to offer a powerful, if temporary, resistance to the pursuers, should keep the enemy at bay, and cover the main body, while the latter with its artillery and stores falls back upon a fresh position. (2) The R. is the bugle sound followed by the beating of drums (or sound of trumpets in cavalry) which is given in all garrisons at sunset, marking the time when all trumpet and bugle calls and drums must cease, except at tattoo or as alarms, till the Reveille (q. v.) next morning.

Retrenchment, a line of works formed within a fortress, in which the garrison may continue the defence after the fortress has been entered by the enemy.

Retriever, a variety of the Dog (q. v.), valued by sportsmen for its skill in fetching game, and for its general sagacity in the field and in the water. There appear to be two breeds, one formed by crossing the Newfoundland and setter, the other by crossing the water-spaniel and terrier. The former is the larger and more familiar breed. A typical R. attains a height of from 20 to 22 inches. Its body is stoutly built and its limbs strong, the toes being webbed. The fur is black and curly. The brown R. is not considered so pure as the black. In training the R. great care has to be taken to prevent the dog from injuring the game it secures.

Retrograde, the term applied to the motion of a heavenly body when it takes place in a direction contrary to the order of

the signs of the Zodiac. The sun and moon have no retrograde motion; with the planets, however, it is otherwise. To an observer stationed at any fixed point external to a planet's orbit, the planet will appear first to move from right to left, and then from left to right. An observer stationed on the earth is of course moving; but this simply modifies the phenomenon for the inferior planets, and gives rise to the phenomenon in the case of the superior planets. It is purely a question of relative motion, and since the motion of any planet is sometimes direct, sometimes R., it follows that at intermediate times the planet must beat an apparent standstill. It is then said to be *stationary*. See PLANETS.

Retz, Jean François Paul de Gondy, Cardinal de, was born at Montmirail, Seine-et-Marne, October 1614. His father was general of the galleys, and his uncle was Archbishop of Paris. Destined for the Church, in which an early developed aptitude for diplomacy seemed to promise him promotion, he was educated by Vincent de Paul, who had to wink at a good many of his pupil's follies. Up to the age of eighteen the young divine was known only as a successful gallant, though he was small and ill-formed; but in 1632 he published the *Conjuration de Fiesque*, a book which caused Richelieu to remark, '*Voilà un dangereux esprit*.' At twenty he preached before the court, and making a name at the Sorbonne as a theological debater, he was introduced to the notice of Louis XIII., who on his deathbed appointed him coadjutor to his uncle, the Archbishop of Paris. For seven years he was the implacable adversary of Mazarin, to thwart whom he set at defiance the authority of the crown, and obstinately refusing to resign his ecclesiastical position, became the most energetic and unscrupulous of the Frondeurs (see FRONDE). On Mazarin's fall, he was selected as Minister by the Queen-regent, Anne of Austria, and after much plotting, received the cardinal's hat in 1651. Mazarin, on his return to power in the following year, had him imprisoned on a charge of conspiracy, but he escaped to Spain, and thence to Italy. During this exile he worked hard in the cause of Charles II. On the death of his enemy Mazarin (1661) he returned to Paris, but Louis XIV., having declared that he should never regain the archbishopric, he was forced to resign, gaining instead the abbacy of Saint Denis and several other benefices, with leave to retire to Commerce. He then sold his estates and paid off his heavy debts, of which he had once arrogantly said, when reproached with their number, that Cæsar, at his age, had six times as many. During his retirement he composed his inimitable *Mémoires*, in which the society he moved in down to 1655 is faithfully portrayed. Than these, even in French literature, there exist no memoirs more perfect in literary grace, or more valuable for historic truth. De R. died at Paris, August 24, 1679. The *Mémoires* were first published in 1717; the best editions are those of Champollion-Figeac (4 vols. 1859), and Feillet and Gourdalet (8 vols. Par. Hachette & Co. 1874-77). See also Léonce Curnier, *Le Cardinal de R. et son Temps* (2 vols. 1862); Topin, *Le Cardinal de R., son Génie et ses Écrits* (1872); Grazier, *Les Dernières Années du Cardinal de R.* (1876), and Chantelauze, *Le Cardinal de R. et l'Affaire du Chapeau* (2 vols. 8vo, 1878). The last work is the first instalment of an elaborate biography of the coadjutor for which M. Chantelauze has been collecting materials for sixteen years. The correspondence of De R. with the Abbé Charrier, discovered by M. Chantelauze, occupies the second volume, and is followed by letters of Louis XIV., Mazarin, the Comte de Brienne, Scarron, &c., all relating to the negotiations so indefatigably prosecuted at Rome for the purpose of obtaining a cardinal's hat for the coadjutor.

Retzsch, Moritz, a German designer, miniaturist, and etcher, was born at Dresden, 9th December 1779. He studied at the academy of Dresden, where he became a portrait painter, and was made professor of painting in 1824. His reputation as an artist of bold, fertile fancy rests mainly on his outline illustrations of Goethe's *Faust* (26 plates, 1812; enlarged ed. 1834), and of the works of Schiller, Shakespeare, Bürger, Fouqué, &c. He also produced several beautiful designs in Greek mythology, but perhaps the most striking of his original subjects was the 'Chess-Players'—Satan playing with man, whose soul is the stake. R. died at Hoffösnitz, near Dresden, 11th June 1857. A new edition of *Luze of R.'s Outlines* was published by Messrs. Sampson Low & Co. in 1875.

Reuchlin, Johann, one of the greatest of the 'Humanists,' and a pioneer of the Reformation in Germany, was born at Pforzheim in Baden, 28th December 1455. After studying

(from 1470) at Freiburg, he became the travelling companion (1473) of Prince Friedrich, son of the Markgraf Karl of Baden-Durlach, with whom he visited Paris in 1473, there making his first acquaintance with Greek. From 1474 he studied and lectured at Basel, where he took his Master's degree in 1477. After this he studied Greek in Paris, law at Orleans (1478) and Poitiers (1479), and had scarcely settled at Tübingen (1481) as an advocate and teacher of Greek when the Graf Eberhard im Bart appointed him his private secretary. In 1482 he attended Eberhard to Rome, and on his return was introduced to the learned circle at the court of Lorenzo de Medici at Florence. At this time he changed his name R. to the Hellenized form *Kapnio* (*kapnos*, 'reek'). In 1484 R. was made an assessor in the high court at Stuttgart, and from 1485 he also practised as an advocate of the Dominican Order. During a visit to the court of the Emperor Friedrich III. at Linz (1492-93), he learnt Hebrew from Loans, the Emperor's Jewish physician, and was promoted to the rank of a 'Pfalzgraf.' On the death of Eberhard (1496), R. fled for fear of his son to the Chancellor Johann von Dalberg at Heidelberg, and the year after the Elector Philipp appointed him tutor to his sons, with whom he spent a year in Rome (1498-99). After this he settled at Stuttgart, and from 1502 to 1513 represented Philipp at the Swabian 'Bundesgericht' at Tübingen. In 1509 began the famous controversy with Pfefferkorn, a baptized Jew of Köln, who demanded the burning of all Hebrew books save the Bible, and with the aid of the inquisitor Jacob von Hoogstraeten reviled R. in a treatise which they named *Speculum Manuale* or *Handspiegel* (1510). In *Speculum Oculare* or *Augenspiegel* (1511) R. paid them back in their own coin. The enraged Dominicans impudently summoned him before their heresy tribunal, but Leo X. caused the bishops of Speyer and Worms to acquit R. and condemn the Kölners to pay the costs of the controversy. Yet there was no peace for R. till Franz von Sickingen extorted the costs from the Dominicans themselves. Meanwhile R. had been driven from Stuttgart by the Swabian wars (1519), and was teaching Greek and Hebrew at Ingolstadt. Disputes with Eck drove him back to Stuttgart in 1521. Appointed professor of Greek at Tübingen, he died at Stuttgart, 30th June 1522, before entering on office. Notwithstanding his unquestioning obedience and devotion to Mother Church, which led him even to withdraw his favour from his nephew and pupil Melancthon, R. was a mighty worker for the Reformation, not so much through his excellent school-books and editions of classic authors, or even his bold defiance of Scholasticism, as through his being the founder of Hebrew studies within the Church. His system of Greek pronunciation, caught from living Greeks, and, from the prevalence of the long sound of Gr. *z*, nicknamed *Rotacism*, is still called by his name. Many of his works marked an epoch in the studies to which they belong. Such are his *Latin Dictionary* (Basel, 1477) and *Greek Grammar* (*Microphadia*, Orleans, 1478), *De Verbo Mirifico* (Basel 1494), *Progyrnasmata Scenica* (1498), *Rudimenta Lingue Hebraica* (Mörzh, 1506), the first worthy Hebrew grammar by a Christian, and *De Arte Cabbalistica* (1516). See Geiger, *Johann R., sein Leben und seine Werke* (Leips. 1871).

Reumont, Alfred von, born at Aachen, August 15, 1808, studied at Bonn and Heidelberg, and, after filling various diplomatic posts at Florence, Constantinople, and the Papal court, was successively Prussian Minister at Florence, Modena, and Parma from 1851 till 1860, when he retired into private life. He has since resided at Bonn and Rome, and in 1876 received the freedom of the city of Florence. R. is author of valuable works on Italian history, *Beiträge zur Italienischen Geschichte* (6 vols. Berl. 1853-57), *Geschichte der Stadt Rom* (3 vols. Berl. 1867-70), *Lorenzo de Medici il Magnifico* (2 vols. Leip. 1874; Eng. trans. 1876), *Geschichte Toscanas seit dem Untergange des Florentinischen Freistaat* (2 vols. Gotha, 1876-77), &c. See his *Biographische Denkblätter, nach Persönlichen Erinnerungen* (Leip. 1878).

Réunion, Ile de la, or Bourbon, an island in the Indian Ocean, belonging to France, and 90 miles W.S.W. of Mauritius. It is elliptical in form, and about 104 miles in circumference, with an area of 950 sq. miles. It is very mountainous, its principal peaks being the Piton de Nieges, 10,000 feet high; Grand Bernard, 9500 feet; Cimandef, 7300 feet; and the Piton de Fournaise, 7200 feet. The last named, which is situated near the S.E. extremity of the island, is an active volcano, its eruptions averaging two annually for ninety years past.

The country around it is, in consequence, so sterile as to be termed the *Pays Brûlé* ('burned land'). The coast districts, however, are clothed with a rich and varied vegetation, and yield heavy crops. The streams are numerous, but are mere torrents running in deep ravines. The climate has of late greatly deteriorated, and is now very deadly to Europeans. Hurricanes are frequent, and cause immense damage both to the crops and to vessels on the coast, which is exposed and almost shelterless. The principal crop cultivated is sugar, of which 35,450 tons were exported in the season 1875-76. Next in importance come coffee and vanilla, the exports of which in 1876 amounted to 833,800 lbs. and 55,850 lbs. respectively. The plantations are cultivated by the labour of Indian coolies, of whom there were 45,000 in the island in 1876. The imports during the same year amounted in value to £720,000. R. is perhaps the only place in the world where the trade is almost exclusively in the hands of the French. Even rice is almost always imported in French ships. In 1876 there arrived 204 vessels of 74,014 tons, and cleared 207 of 77,858 tons. R. was discovered in 1545 by the Portuguese navigator Mascarenhas, who gave it his own name. In 1642 it was taken possession of by the French, who in 1654 re-named it Ile de Bourbon. In the Revolution its name was changed to R., and in 1809 to Ile Bonaparte. In 1814 it was again named Bourbon, and kept that designation until 1848, when the name R. was once more adopted. The pop. in 1876 was 180,295, including coolies, negroes, and a sprinkling of Chinese. The capital, St. Denis, has a pop. of 32,050, and the next largest town is St. Pierre, on the S.W. coast, with 30,615 inhabitants. See Drache's *Insel R., eine Geologisch-Petrologische Studie* (Weim. 1877).

Reus (pron. Re-us), a town of Spain, province of Tarragona, about 6 miles inland from its port of Salou, and 8 W.N.W. of Tarragona by rail. It was founded in 1151, and in 1750 a number of Englishmen established its prosperity by introducing various industries. In recent years its cotton-mills had 5000 looms, while there were also manufactures of ribbons, silk, leather, soap, and machinery. In the province were 69 cotton spinning-mills, with 2000 hands and 53,000 spindles, and 179 weaving-mills, with 5000 hands and 2691 looms. Pop. 28,100.

Reuss, the name of two German principalities which occupy part of the ancient Voigtland, and lie W. of the kingdom of Saxony, separated from each other by the circle of Neustadt. Previous to 1616 they formed one principality, but at that date the territory was divided between the elder and younger lines of the house of R., which traces its descent from Heinrich I. (q. v.). —1. **R. Greiz** is bounded N. and E. by Saxony and Saxe-Weimar, S. by Bavaria, and W. by Saxe-Coburg and Schwartzburg-Rudolstadt. Area, 320 sq. miles; pop. (1875) 46,985. The surface is mountainous and well wooded, while the soil is poor, except in the fertile river-valleys, the chief of which are those of the Saale and Elster. In the towns, woollens, cottons, and silks are manufactured. The capital is Greiz. Most of the territory is the private property of the present sovereign, who has no civil list. By the present constitution, which dates from 1867, the legislative body consists of twelve members, of whom three are nominated by the sovereign, two by the nobility, three elected by the towns, and four by the rural districts. The public revenue and expenditure in 1876 were each £24,494. There is a public debt of £65,475. —2. **R. Gera**, formerly **R. Schleiz**, is bounded N. by Prussia, S. by Saxony, and E. and W. by different parts of Altenburg. Area, 322 sq. miles; pop. (1875) 92,375. It is in part hilly, and more than one-fourth is covered with wood. The soil is productive though light, and is well watered by the Elster and its affluents. Cottons and woollens are extensively manufactured, especially in Gera, the capital, besides leather, tobacco, and ironwares. The constitution dates from 1849 (modified 1852 and 1856), and provides for a Diet of nineteen members (four elected by the chief landowners), and a cabinet of three to act under the sovereign. The revenue in 1876 was £36,480, and the debt £100,027. The inhabitants of both states are almost entirely Lutherans.

Reuter, Baron Paul Julius, the great organiser of telegraphic news, was born at Cassel in 1818. He was connected with the electric telegraph system from its beginning, and shortly after the opening of the line between Aix-la-Chapelle and Berlin in

1849 he established the first centre for the collection and distribution of telegraphic news in the latter city. He subsequently became a naturalised British subject, and transferred his chief office to London on the laying of the cable between Calais and Dover in 1851. As the telegraphic system extended he increased his staff of agents, till in recent years he has been able to supply newspapers indiscriminately with full, fresh, reliable information from all parts of the world. In 1865 this vast news agency was transferred to a limited liability company, of which R. is still manager. By his negotiation the right was acquired of laying special submarine cables between England and Germany (1866), and between France and the United States (1869). For his public services R. received the title of Baron from the Duke of Coburg-Gotha in 1871. In the following year he was granted by the Shah of Persia the exclusive right, for seventy years, of constructing railways, working mines and forests, and otherwise developing the resources of that country. Baron R. began vigorously to construct the line from Teheran to Resht, but he has been interdicted on account of the threatening aspect of native jealousy and Russian intrigue.

Reutlingen, formerly an imperial free town in Württemberg, situated on the Echatz, an affluent of the Neckar, 9 miles W.N.W. of Tübingen by rail. It contains many picturesque old houses, but its ancient ramparts and fosses have been converted into streets. The finest church is the Marienkirche (1272-1343, restored 1844). R. has an active manufacture of leather, woollens, cottons, lace, knitted wares, cast-iron, and machinery. Pop. (1875) 15,246.

Revalen'ta and Ervalen'ta are preparations of the flour of the lentil, *Ervum lens* (hence *Ervalemta*, and by transposition R.). Du Barry's much-vaunted panacea, *R. Arabica*, is composed, according to Dr. Hassall, of a mixture of the red or Arabian lentil and barley-flour, to which, in one kind sugar, and in another, salt is added.

Reveill   (Fr. *r  veil*, 'awakening'), the morning beat of drums or bugle sound in all garrisons, upon which the troops rise. It is sounded in England at 5.30 in summer and 6.30 in winter. After the R., sentries do not challenge till the retreat is sounded at evening.

Revel, or **Reval** (Esthonian *Tallin*, Lithuanian *Dannuþils*, or *K  vele*), a fortified seaport of Russia, capital of the government of Esthonia, on the Gulf of Finland, 198 miles W. by S. of St. Petersburg. It consists of an upper portion, called the Domberg ('Cathedral Hill'), a circular mass of rock a mile in circumference, with the cathedral, the governor's residence, the Ritterschafshaus ('Senate Hall'), and an old castle; and a lower, with high narrow houses, and six Lutheran and five Russian churches, of which that of St. Nicholas dates from 1317. In 1875 there entered the port of R. 467 vessels of 234,481 tons, and cleared 460 of 221,645 tons. Founded by Valdemar II. of Denmark in 1219, R. soon increased, and entered the Hansa. In 1347 the Danes sold it to the Teutonic Knights, from whom it passed to Sweden (1561), which held it till Peter the Great annexed the province of Esthonia to Russia. Pop. (1870) 27,325.

Revela'tion means the communication to man by supernatural means of such knowledge as he could not attain to by ordinary means, or of information which the person receiving it at any rate did not possess. It is not to be confounded with Inspiration (q. v.), which means a divine influence rendering a person infallible in communicating truth, whether that truth was previously known or not. Rationalists deny (1) that there is any R. in this sense, and (2) that it is possible or (3) necessary. Divines, on the other hand, maintain (1) that it is possible and (2) necessary, and (3) that there is such a R. in the Word of God. See Hodge's *Syst. Theol.* (Edinb. 1873).

Revela'tion of St. John, the last book of the New Testament, is ascribed in the canon to St. John the Divine. The received opinion is that this was the apostle, the accredited author of the Fourth Gospel, although a doubt on the subject was started as early as the 3d c. by Dionysius of Alexandria (*apud* Eusebius). Luther, Zwinglius, Eccolampadius, and Bucer expressed the same doubt more decidedly, and many eminent critics since—L  cke, Ewald, Neander, Bleek, De Wette, &c.—have held the same opinion. In favour of the apostolic authorship it is urged—(1) that the external evidence is as strong as that

for any other book in the New Testament; and (2) the internal evidence—i.e., the ideas regarding Christ, Antichrist, evil spirits, and the last things—are those of apostolic times. And if it be apostolic, no man but St. John could lay claim to the position and privileges which the writer asserts. A difficulty arises from the differences in doctrine, theology, and language between the Revelation and the Fourth Gospel. Accordingly, some critics give the one to St. John; some, the other; some, neither; those who try to give him both find hard work in getting over the difficulties. As to the time and place, the received opinion is that it was written in Patmos under Domitian (81-96) or Nerva (96-98). There is no external evidence further than tradition; but xi. 1-14 is supposed to indicate that Jerusalem was not yet destroyed (70), while xvii. 10 is quoted as proof that it was written during the reign of the sixth emperor, i.e., Galba (68-69). The object of the writer is 'to set forth the immediate coming of Christ, in order to support his followers under calamities already endured and still impending.' See Davidson's *Introd. to the New Test.* (Lond. 1868); Stewart's *Com. on the Apoc.* (1845); D  sterdieck, *Handbuch   ber der Offenb. Joh.* (G  tt. 1865).

Revelunge, a town in the district of Sarun, Bengal, British India, at the junction of the Gogra with the Ganges, on the left bank of both rivers, 31 miles N.W. of Patna. The old name was Godna; but in 1788 Mr. Revell, Collector of Customs, founded a bazar which has since become the greatest river mart for oil-seeds in India. It is the station where commodities from the N.W. Provinces and Oude are transhipped. In 1876-77 the exports were valued at £471,000, chiefly oil-seeds; the imports at £563,000, including grain, salt, and piece-goods. A great fair and religious gathering is held here twice a year. Pop. (1872) 13,415.

Revels, Master of the, or **Lord of Misrule**, at the great English houses was a functionary charged with the conduct of the Christmas revels from Allhallow Eve to Candlemas Day. The post was rendered permanent under Henry VIII. at the English court, its holder having the keeping of the properties used in the royal masques and progresses, and it existed down to the close of the 17th c.

Revenue (Fr. *revenu*, from *revenir*, 'to return'), a return of gain or profit. 'The R. from labour,' says Adam Smith, 'is called wages; that derived from stock . . . is called profit.' The term is now most generally used to express the public income of a nation raised by taxes, duties, &c., and applied to the purposes of Government. The ancient public R. of England chiefly accrued from crown lands, which, however, became in the course of time so reduced in extent by alienation to lords of the manor and other causes, that the R. arising from this source, known as 'ordinary R.' has long been inconsiderable, while the 'extraordinary R.' derived from the taxes imposed by Parliament has constituted the great bulk of the R. of the country. The granting of Supply is vested in the House of Commons, and all alterations in the system of taxation are based upon the annual financial statement made by the Chancellor of the Exchequer in the beginning of April, and known as the Budget. Although the ultimate assent of the House of Lords and the crown is required, the taxes imposed by the lower House are levied immediately after the carrying of their resolutions. The public R. is paid into the Bank of England to the credit of the Comptroller-General of the Exchequer, whilst the function of payment of outgoings is vested in the Treasury. The following is the actual R. of the United Kingdom for the year ending 31st March 1878, and the estimated R. for the year ending 31st March 1879:—

	Actual Revenue 1877-78.	Estimated Revenue 1878-79.
Customs	£19,969,000	£19,750,000
Excise	27,464,000	27,500,000
Stamps	10,956,000	10,930,000
Land-Tax	2,670,000	2,600,000
Property-Tax	5,820,000	5,620,000
Post Office	6,150,000	6,200,000
Telegraph Service	1,310,000	1,315,000
Crown Lands	410,000	410,000
Interest, &c.	949,884	1,075,500
Miscellaneous	4,064,415	4,000,000
	£79,763,299	£79,460,000

The actual expenditure for the year ended 31st March 1878 was—

For the Civil Service	£13,982,267
" Army and Navy	30,054,335
" Debt and Consolidated Fund Charges	27,090,757
" Other Charges	7,776,136
	£78,903,495

The most important source of R. from direct taxation is the income-tax, which is also the most liable to alteration on account of financial exigencies. It has undergone twenty alterations from its establishment in its present form in 1842 until 1878 inclusive, the highest rate levied being 16d. in the pound in 1855, and the lowest 2d. in the pound in 1874 and 1875.

The above statement of R. does not by any means represent the total charge levied upon British taxpayers, but only the amount raised for imperial purposes. An immense R. is raised by local taxation and other sources to provide for expenditure connected with the relief of the poor, the county and borough police, roads and bridges, the draining and lighting of towns. The following is the amount raised in this manner in Great Britain and Ireland in the year ending 31st March 1874, according to the best estimates obtainable :—

	Receipts from Taxes.	From Loans.	Total Local Revenue.
England and Wales	£23,897,029	£8,201,499	£37,731,193
Scotland (partly estimated)	2,372,557	149,494	3,202,714
Ireland	2,996,009	129,493	4,599,908
	£29,265,595	£8,480,486	£45,533,815

In the same year the total amount of taxes received at the Exchequer, and levied locally, amounted to £2, 18s. 11d. per head of the population of the United Kingdom.

Undernoted is given a table showing the R. of the leading states in the world in various recent years :—

Austro-Hungary, 1877	£59,497,730
Belgium, 1877	10,101,830
Brazil, 1872-73	11,213,110
British India, 1876	51,310,063
Canada, 1876	8,615,618
China (average Imperial Revenue estimated at)	25,000,000
Denmark, 1877-78	2,734,189
France, 1877	106,885,620
German Empire (for Imperial purposes) estimated, 1878	27,000,000
Prussia, 1878 (estimated)	32,581,920
Bavaria, 1875	10,602,593
Greece, 1877	1,401,678
Italy, 1877	59,564,396
Japan, 1874	9,750,000
Mexico, 1875	3,741,407
Netherlands, 1876	8,642,556
Portugal, 1876-77	5,346,661
Russia, 1877	81,539,714
Spain, 1878 (estimated)	29,433,000
Sweden, 1878	4,782,778
Switzerland, 1876	1,659,496
Turkey, 1875-76	19,104,352
United States, 1878 (estimated)	\$270,050,000

The Actual R. drawn by a country is no criterion of its wealth or of the tax-bearing strain it is able to bear. Thus France is probably no richer than it was a few years ago, although its enormously increased expenditure on account of the war with Germany and the interest on its augmented debt (which has been hitherto met principally by the imposition of indirect taxes) has caused a corresponding increase in its R. It is believed that the R. of Great Britain is capable of greater expansion than that of any other country.

Reverberatory Furnace is a form of furnace in most extensive use in metallurgical and in many other chemical operations. The construction of a R. F. varies considerably for different purposes, but in principle it consists of a device for throwing heat downward on the material to be operated on. The R. F. consists of a low arched vault, on the bed of which the metal or other substance is laid. The fire-box is at one end of the furnace, partially separated by a fire-bridge, over which and along the vaulted roof the flame freely plays, reverberating the heat downwards. The R. F. gives free access of air to the material, and is thus employed for oxidising impurities in metals and other similar purposes.

Reverend (Lat. 'venerable') is a title of respect applied to the clergy: the bare R. to ordinary clergymen, Very R. to deans (in Scotland to the Moderator of the General Assembly, and clerical Principals of Universities), Right R. to bishops, and Most R. to archbishops. After the Reformation the Puritans objected to the title being applied to any man, as belonging to God only; and at one time Dissenting ministers repudiated it, but it is now adopted, at least in the principal sects.

Reverse, in numismatics, that side of a coin or medal opposed to the face or *obverse* side, on which is impressed the principal device. The value of a coin is usually indicated on the R.

Reversion is a right to property, to emerge after the ending of an interest in it held by another. If A is to enjoy the profits of an estate during his life, and on his death the estate, or the life interest in it, is to go to B, then B's interest is a R.

Revetment, in fortification, is a wall of solid masonry intended to retain the earth of which the works are composed. Revetments usually form the escarp and counterscarp of the ditch. See FORTIFICATION.

Review, an inspection of military or naval forces by a distinguished personage or high officer, which may be accompanied by manoeuvres and evolutions. A review of troops usually consists of a quick march past in columns, sometimes followed by a sham fight.

Revising Barrister, is a legal functionary whose duties are to revise the lists of persons claiming to vote for members of Parliament, and to adjudicate upon these. An appeal from his decision may be made to the Common Pleas division. The appointment is in theory annual, but the same person is invariably reappointed. The R. B. must have been at least three years at the bar. His duties are, in Scotland, embraced in those of the Sheriff-Substitute.

Revival, like Revolution, is one of those vague terms loosely applied to widely different movements. As one may rouse a sluggard whose house is on fire in time for him to quench the flames, or disturb an honest craft-man from his labour by false alarms, so the times of awakening known as 'Revivals' must be judged first by the message they proclaim, still more by their results. Far stronger testimony to the work of Pentecost than the recorded conversion of 3000 souls, or even than St. Peter's great discourse, is the continuance of the work down to this very day, in the steady evangelisation of the entire world. Excitement was never greater than when at the Council of Clermont the Hermit's wild harangue was interrupted by the shout, 'God wills it!' That God did *not* will it was shown by the whitening bones of those who had raised the cry. And so every religious movement, whether set agoing by a Dominic, a Luther, a Xavier, or a Wesley, may be known by its fruits; among the rest, the Revivals of modern times. Christians of almost every creed will grant that there is nothing in the apostolic ministry needing defence; of Revivals their warmest upholders have constantly to speak in an apologetic tone. Thus the narrative of the first important movement of the kind, the New Jersey R., under Mr. Tennent (1730), couples 'much that was objectionable' with 'the characteristics of true conversion'; and in Jonathan Edwards' R. (1735-41) the 'outward reformation in the lives of more than 43,000 persons' is attended by 'manifestations' such as 'convulsions, nervous prostration, and abiding terrors.' Similarly the rise of Wesleyan Methodism in England was characterised by 'persons quaking and trembling as in ague, torn by dreadful torments, which left them weak as infants, falling to the ground as if struck by lightning, and lying in a state of insensibility, or howling and roaring in agony,' all this, be it observed, after conversion (*cf.* Luke viii. 35). Wesley himself, says Southey, lost faith in these paroxysms, and by ceasing to encourage them, caused their cessation. Again, in the Cambuslang R. of 1742 men and women 'were smitten by scores, and carried off into the neighbouring houses like wounded soldiers from a field of battle; . . . people of both sexes, from the stoutest man to the tenderest child, shake and tremble, and a few fall down as dead.' In the next hundred years we can only glance at the Truro R. of Walker (1758), that of Venn at Huddersfield (1759), a third and more extensive one under Berdridge's ministry in the Eastern counties (1760), and the singular R. in the Western States (1804), in which were developed the

'falling,' the 'jerking,' and the 'whirling exercise'—extravagances perpetuated by the Shakers, Marshallites, and kindred sects. The American R. of 1858, at New York, Philadelphia, and other cities, was happily distinguished by an absence of all physical manifestations; the ministers, schooled in the annals of former undisciplined enthusiasm, 'uttered simple statements of Gospel truth, and avoided all appeals to the emotions;' and the solid results were 'the reception into the communion of the churches of some 500,000 persons.' Not so with the corresponding movement in the N. of Ireland (1858-61), when a leading revivalist could thus describe a case 'exceeding in beauty and abundance of grace' all that he had yet witnessed in the 600 cases he had seen: 'I was called to see Jane; it had taken four men to hold her, and her shrieks were awful; she had been insensible for hours, &c. What wonder that mills were closed in consequence of the number of 'stricken' operatives; what compensation for such facts as these the statement that 'a considerable number of Romanists renounced their errors, that Sabbath desecration, cockfighting, brawling, and the like are now nearly unknown in several districts, while the constabulary force was in some places almost a sinecure.' Yet, though the Irish population has steadily dwindled from 6,574,278 in 1851 to 5,402,759 in 1871, there were 4,490,583 Romanists in 1861 and 4,191,933 in 1871, and criminal convictions actually rose from 3350 (1858) to 3798 (1862), the number of lunatics from 11,218 (1858) to 17,193 (1870), and of police—whether their duties are a sinecure or no—from 12,346 (1852) to 14,007 (1870). One good at least the Irish R. did: it served for warning to the American revivalists of 1874, Messrs. Moody (q. v.) and Sankey. Whether 'raciness, pithiness, and humour' were meant to supersede Christ's Sermon on the Mount or St. Paul's at Athens, whether it is wise that 'quite little children' should publicly express themselves as 'deeply exercised by the Spirit,' or how far it is needful that 'Old Formality have his neck broken'—these may be matters of opinion; but that the first outburst of howling was met by the howler's prompt ejection can only be matter for unmixed satisfaction. See *Præterition hægion Apostolon*; Lives of Edwards and Wesley; Dr. G. Salmon's *Evidences of the Work of the Holy Spirit* (Dubl. 1859); and *Narrative of the Awakening* (Lond. 1874).

Revocation is a law-term denoting the act of annulling a deed. Many kinds of deeds are irrevocable if delivered. (See DELIVERY OF A DEED.) A will is always revocable; and it may be revoked by implication, as by *marriage*. See also CANCELLING and WILL.

Revolution (Late Lat. *revolutio*, from *revolvere*), in politics, a sudden and violent change of government, mainly brought about by internal causes. A change brought about by external causes is generally of the nature of a *conquest*, while a gradual and pacific internal change is a *reform*. It is only in comparatively modern times that the word has been used in the present sense, but ancient history abounds in revolutions, such as, for instance, the expulsion of the Pisistratids from Athens (B.C. 510), or the overthrow of the Roman Republic by Julius Cæsar (B.C. 47). The first great R. of modern history is the English R., extending through various phases, from about 1642 to 1688, but usually confined, in common parlance, to the convulsion by which James II. was driven from the throne in 1688. The Great R. *par excellence* is the French R. of 1789-94. There have been other revolutions in France in 1830, 1848, 1851, 1870, and 1871. The American War of Independence (1775) is often called a R.; and revolutions have been very frequent in Mexico and the Spanish states of S. America. In Italy the R. of 1859-60 expelled the small potentates, and placed the whole country except the Papal and Venetian territory in the hands of Victor Emmanuel. Among other notable revolutions have been those of Sweden (1772 and 1809), Spain (1820 and 1868), and Hungary (1848). The famous Revolt of the Netherlands, which began in 1566, partook of the nature of a R., and there have been revolutions in Holland in 1795 and 1813. The reaction from a R. often brings about what is called a Counter-R.

Revolutionary Tribunal. See REIGN OF TERROR.

Revolver, a firearm having a revolving breech-piece or barrel so as to discharge several shots in succession without the

need for reloading. The revolving system is not a modern novelty, for it was in use in Germany as early as the end of the 15th c. A 16th c. matchlock, with a rotating breech-piece containing four chambers, is exhibited in the Tower armoury of London, and a revolving arquebus with seven barrels is preserved in the museum at Sigmaringen. The system was revived early in this century and has since been brought to great perfection. Although some weapons have a plurality of bores in the barrel which itself revolves, the plan of having a revolving breech cylinder with a number of chambers which are successively brought opposite a single barrel is more convenient and practicable. The first R. adapted to modern requirements was invented in 1835, and perfected ten years later by the late Colonel

Colt's Revolver.

Colt. His R. pistol, which is universally used, is here figured. The barrel is of steel and rifled. The rotating breech-piece is cylindrical, contains six chambers, and each one has at its rear end a nipple for a cap. Placing the hammer at half-cock, the chambers are loaded from the front of the breech-piece, which is now turned by the hand, and the charges are driven home by a lever ramrod placed in a socket beneath the barrel. The breech-piece rotates on a pin or spindle secured at one end to the lock-frame and at the other to the bracket piece united to the barrel. On the rear face of the breech-piece is cut a ratchet with six teeth, and a pawl connected with the hammer, engaging the teeth in succession, turns the breech-piece. When the hammer is at full-cock, one of the loaded chambers is directly in a line with the barrel, and the rotating cylinder is temporarily held in that position by a small bolt entering a slot (six slots being cut on the periphery of the cylinder) on the under side. The weapon may then be fired by pulling the trigger. The raising again of the hammer with the thumb serves to withdraw the bolt, releases the cylinder, and causes the pawl to turn it one-sixth of a revolution; this movement brings the next chamber opposite the barrel, and immediately the bolt falls into the next slot and locks the cylinder. Colt's revolving mechanism has also been applied to muskets and rifles. Several other revolvers have been introduced, and some of recent Continental manufacture are adapted for self-igniting cartridges, an improvement upon Colt's nipple and cap that is worthy of mention. Adams' R. pistol with a metallic central-fire cartridge has been adopted for the British cavalry and navy. The revolving principle has been successfully adapted to several varieties of battery guns, that invented by Gatling having the widest reputation. See MITRAILLEUSE.

Revolving Furnace. Furnaces to which a motion of rotation is communicated have been introduced with marked success in some chemical manufactures, and a measure of success has also attended the introduction of a rotary furnace in the laborious operation of Puddling (q. v.) in the malleable iron manufacture. The most successful R. F. is that used in the calcination of soda salts in the process termed 'carbonating' (see SODIUM). Among the various forms proposed, that devised and patented by Mr. James Mactear (of Charles Tennant & Co., St Rollox, Glasgow), is the best and most practical. The rotation of the furnace keeps the charge it contains in constant motion, exposes it uniformly to the heat, and saves a great amount of disagreeable manual labour. The soda ash produced is not only made at much less cost, but it is also of finer quality than that made in a reverberatory furnace. The apparatus is applicable to many chemical processes in which reverberatory furnaces are at present used. Of R. F. employed in the iron manufacture, that invented by the American, Danks, for mechanical puddling has met with much attention, and Dr. C. W. Siemens' rotary furnace for making malleable iron direct from the ore is an invention which may yet be productive of great changes in the iron manufacture.

Revulsion is a term used in medicine synonymous with Derivation (q. v.). See also COUNTER-IRRITATION.

Rewá Kantá Agency, a collection of native States in Gujerat, India, in political connection with the government of Bombay: area, 4879 sq. miles: pop. (1872) 487,647, who chiefly belong to the wild tribes of Bheels and Mewassis. There are six larger states, of which the chief is Rajpeepia; and fifty-six smaller chiefships; most are tributary to the Gaekwar of Baroda, and all levy transit dues. In 1842 a Court of Criminal Justice was established, presided over by the Political Agent, and in 1874 a police force was organised.

Rewah or Baghelcund ('country of tiger cubs'), the capital of a native state of the same name in Central India, 69 miles S.W. of Allahabad. It was founded about 1620, and is strongly walled, with a fortified palace, but all is now ruinous.—The *State of R.*, which is the first in the Baghelcund Agency, lies between the N.W. and the Central Provinces: area, 13,000 sq. miles; pop. about 2,035,000; revenue, £250,000, of which £150,000 is alienated in feudal and religious grants. The country is mostly a plateau among the Kymur hills, and is rich in minerals and jungle produce. The administration is backward, and there is a debt of £70,000. The present chief, who is a Rajput of the Baghel clan, traces back his family for 1200 years. For his services in the Mutiny of 1857 he was presented with an addition of territory which forms the watershed of Central India, containing the sources of the Nerbudda, the Sone, and the Mahanuddi Rivers. In 1875 the Rajah requested that the administration should be directly undertaken by the British Political Agent, and this step has been adopted.

Rewards, Légal. The law courts of England are empowered by Act of Parliament pecuniarily to reward those who have been active in apprehending persons charged with crime of a certain gravity. Any one taking a reward for helping in the restoration of stolen or embezzled goods or money to the owner is guilty of felony.

Rewards for Distinguished Services, in the British army, are annuities granted to officers of the higher grades who have distinguished themselves in the field, or have done good service to the state. The rewards, usually £100 per annum, cease on a receiver's succession to the colonelcy of a regiment, or in the Indian army when his emoluments otherwise amount to £1000 a year. Annuities of from £10 to £20 are granted to meritorious non-commissioned officers. See PENSIONERS.

Rewári, the chief town in the district of Gurgaon, Punjab, British India, 50 miles S.W. of Delhi. Pop. (1868) 24,503. It is a station on the newly opened Rajputana State Railway. In 1873-74, exclusive of the railway traffic, the imports were valued at £108,000, the exports at £22,000.

Reyk'ia'vik ('the reeky bay,' from the warm springs near), the capital of Iceland (q. v.), and seat of the Althing, lies on the S.W. coast, on the S. shore of the Kollafjord. It consists of about 100 wooden houses, regularly built in a barren, treeless district, usually enveloped in mist. It is a bishop's see, and has a brick cathedral (*Domkirkja*), containing a library (8000 vols.) founded by Rafn; a 'Latin school'; a theological college; a printing press; and a bronze statue of Thorvaldsen (1875). The mean temperature of R. (40° F.) is but 1° F. less than that of St. John, 16° lat. further S. Pop. (1870) 2024, chiefly merchants, peasants, and fishermen. 27 miles E. of R. is *Skalholt*, once a bishop's see; 28 N. is *Reykholt*, the residence of Snorri Sturluson; and 18 N.E. *Thingvellir*, where in former times the Althing met under the open sky. See Burton, *Ultima Thule, or a Summer in Iceland* (2 vols. Lond. 1875).

Reynard the Fox, the great beast-epic of the Middle Ages, that 'World Saturnalia,' as Carlyle terms it, 'where wolves tansured into monks, and nigh starved by short commons, foxes pilgriming to Rome for absolution, cocks pleading at the judgment-bar, make strange mummery.' Such mummery, in fact, as pleases the infancy of nations, Kafirs and Finns alike, originally mirth-provoking only, afterwards with the nation's growth applied to didactic purposes. The hero of the most ancient version is Isengrim, the wolf, nor till cunning had come to be more admired than strength did Reynard usurp his place. France, Germany, and Holland all claim to be the story's birth-place; that it was ever born, in the sense of being the product of a single mind, may safely be denied. Grimm's theory of its

transmission westward by invading Franks is at first sight neither confirmed nor overthrown by an analysis of names, Reynard (O. H. Ger. *regin-hart*, 'thought-strong') and Isengrim (O. H. Ger. *isan-grim*, 'iron-rough') being as plainly of Teutonic as Chantecler and Malpertuis are of Romanic origin. Malpertuis, however, may just as well be a rendering of Uebelloch as Uebelloch of Malpertuis, and the fact that *renard* has wholly superseded *goupil* (Lat. *vulpes*) in French, certainly points to a Teutonic source. The earliest existing version is the *Isengrimus* (ed. by Mone, Stuttg. 1832), a fragment of 688 lines, succeeded by the *Reinardus Vulpes* (ed. by Knorr, Eutin, 1860), an elegiac poem of 6596 lines, both probably the work of Flemish ecclesiastics in the 12th c. On one or other of these was founded the Middle-High-German *Isengrines Nôt* of the Alsatian minnesinger, Heinrich der Glichesäre (i.e., 'feigner,' or 'one who conceals his name'), and also the Flemish *Reinaert* of Willem van Utenhoven, the former of which has been edited by J. Grimm (Berl. 1834), the latter by Jonckbloet (Gron. 1856), and in its subsequent redacted form by Martin (Paderb. 1874). Willem's poem was the parent of the Dutch prose chap-book (Gouda, 1479), from which Caxton made his English translation (1481), and also of the *Reineke Vos* (Lub. 1498), a free reproduction, in Low German verse, most probably composed by Hermann Barkhusen, a Rostock printer. This *Reineke Vos*, a unique copy of whose first edition exists in the Wolfenbüttel Library, has been repeatedly edited, most recently by Lubben (Olden. 1867) and Schröder (Leips. 1872). It speedily attained a popularity far exceeding that of any of its predecessors, running through countless editions; it was introduced to the High-German world through Beuther's translation (Frankf. 1544), and to the world at large through the Latin rendering of Schopper (Frankf. 1567); and in more recent times it has been popularised in Goethe's hexameters (Berl. 1794; Eng. trans. by T. J. Arnold, 1855), and Kaulbach's illustrations (Mun. 1847). The French *Roman de Renart* consists of two separate portions, the former belonging to the 12th or 13th, the latter to the 14th c. Though far inferior in vigour to its Teutonic analogue, it enjoyed considerable fame, and like it was the source of many quaint old chapbooks, *Le Livre de Maistre R. et de Dame Hersant* (Par. n. d.), *Le Docteur en Malice, Maistre R.* (Rou. 1550), &c. See the Introductions to the various editions cited above; an essay on *Early German Literature* in Carlyle's *Miscellanies*; A. Rothe, *Les Romans du Renart examinés, analysés, et comparés* (Par. 1845); and W. Jonckbloet, *Étude sur le Renart* (1863).

Reynolds, John, D.D., born at Pinho in Devonshire in 1549, studied at Merton College, Oxford. In 1563 he was made Fellow of Corpus Christi, where he lectured on Aristotle, till 1586, when he was elected reader of the theological lecture founded by Sir Francis Walsingham. In 1593 he became Dean of Lincoln, but resigned this office and refused a bishopric on being chosen President of Corpus Christi. He was the leader of the Puritan party, and was profoundly read in Hebrew and theology. At the Hampton Court conferences of 1603, he suggested and strongly urged that a new translation of the Bible should be made, a work in which he took a prominent part, the weekly meetings of the translators being held at his chambers. He died at Oxford in 1607. Besides sermons, controversial treatises, academical discourses, &c., he wrote an elaborate work against the reception of the Apocrypha into the Old Testament Canon, *Censura Librorum Apocryphorum Veteris Testamenti* (Oppenheim, 2 vols. 1611).

Reynolds, Sir Joshua, the prince of English portrait-painters, was born at Plympton, of an old Devonshire family, 16th July 1723. His father, the rector of Plympton St. Mary, intended that he should enter the medical profession; but an ardent love of art, confirmed by study of the *Jesuits Perspective* and Richardson's *Treatise on Painting*, upset this plan, and the youth was placed in Hudson's studio in 1741. In 1743 he disagreed with his master, and set up as a portrait-painter in Plymouth Dock, since called Devonport, where his talents attracted the notice of Captain (afterwards Admiral Lord) Keppel, and Lord Mount Edgecombe. Three years later he went to London, and in 1749 he accompanied Captain Keppel to the Mediterranean, and after spending two months in Minorca proceeded by way of Leghorn to Rome. With singular candour he has recorded his mortification at not being at once enraptured by the works of Raphael; and with equal docility he devoted himself to

assiduous and sympathetic study of Italian art, though not, he tells us, as a mere imitator. 'With Dutch painting and Dutch china for the (then) prevailing types of art,' says Ruskin, 'he threw himself at the feet of the great masters of Italy, and arose from their feet to share their throne.' While studying in the Vatican he caught a cold which gave rise to a life-long deafness. Visiting the other art capitals of Italy, he was influenced, at once more directly and durably, by the glories of Venetian colour than by Roman grandeur and dignity. After a short stay at Paris he returned to Plymouth (1752), and settling in London, produced the Rembrandtesque portrait of Marchi, his Italian assistant, which authoritatively announced the advent of a powerful and original genius. A full-length portrait of Admiral Keppel ratified his reputation, and henceforth his career was an uninterrupted and almost unparalleled success. The long list of his sitters comprises the most famous men and the fairest women of the Georgian age. The envious and cynical, unable to deny the great merit of the painter, attempted to decry his artistic department, and their insidious attacks drew from Dr. Johnson, the warm friend of R., a defence of portrait-painting in the *Idler*. R. was animated by a loftier opinion of portraiture than his advocate, and was enabled by an intense and cultivated gift of insight into nature, coupled with great technical dexterity and resource, to express with even finer subtlety than either Titian or Vandyck the various shades of character and mood, the 'stamp of the soul upon the flesh.' It is urged that R. was governed by ideals of dignity, breeding, and sweetness, to which he made all sitters in a general way conform, but in his tendency to generalise, to grasp the broadly permanent, he never fails to catch every essential characteristic. His unerring truth and consequent variety is shown strikingly in his portraits of women and children, where each has its distinctive loveliness, each its peculiar grace. It was impossible for R. to paint any portrait prosaically, and in the treatment of children he discovered a poetic realm of which, in earlier art, we have occasional glimpses and guesses. The rosy brood, innocently wild or comically wise, almost grow in beauty as they are transferred with loving skill from nature into art by the childless painter. Besides those portraits—e.g., Mrs. Billington as St. Cecilia, and Mrs. Siddons as the Tragic Muse—in which he adopted an allegorical setting, R. painted the 'Infant Hercules strangling the Serpents in the Cradle' for the Empress Catherine, designs for the window of New College Chapel, Oxford, and three works for Boydell's Shakespeare. Like Gainsborough, he was more a colourist than a delineator, and his colours are generally in glowing, golden keys. Chiaroscuro he drew from Rembrandt, colour and tone from the Venetians, and somewhat of all three qualities from Correggio. To his tolerant urbanity may be ascribed his uniform excellence. On the foundation of the Royal Academy in 1768, R. was chosen president, and received the honour of knighthood with the office. As president he delivered his celebrated Discourses, which are now published together with his notes on Dutch and Flemish art, his three contributions to the *Idler*, &c. After a painful illness he died, 23d February 1792. In an eloquent eulge Burke calls his old friend 'the first Englishman who added the praise of the elegant arts to the other glories of his country.' The number of his pictures is estimated by Tom Taylor at nearly 3000, and of these some 700 have been reproduced by the best engravers, including W. Sharp, R. Earlom, W. Doughty, Raphael Smith, W. S. Reynolds, and Samuel Cousins. See besides the monographs of Cunningham and Cotton, the biographies by Northcote (1813), Farington (1819), and C. R. Leslie completed by Tom Taylor (2 vols. 1865); also Stephen's *English Children as Painted by R.* (1866), Sydney Colvin's *English Art under George III.* in the *Fortnightly Review* of March 1, 1874, Dr. Hamilton's *Catalogue Raisonné* (1875), and the vol. upon R. in the American series of *Artist-Biographies*, edited by M. F. Sweetser (Boston, 1878).

Rhadaman'thus. See MINOS.

Rhaetic Beds form the uppermost strata of the Trias formations, and consist of dark shales resting upon white limestone. Formerly they were referred to the Lias, and were included under the name of the *White Lias*. The fossil fishes strongly resemble undoubted Triassic forms; and the reptiles are Jurassic. There are no ammonites or belemnites, but the shell of *Avicula contorta* is very characteristic, whence the old name, *Avicula Contorta Zone*. The present name is derived from the Rhaetian Alps,

where the beds are well developed. They are also well represented in England and Germany.

Rhamna'cese or **Rham'neae**, is a natural order of erect or climbing trees or shrubs, often spiny, with simple leaves usually alternate, and small flowers sometimes unisexual. The order contains 37 genera, embracing about 450 species, and is represented in most countries of the world excepting the arctic zone. The maximum of species occurs through the hottest parts of the United States, the S. of Europe, the N. of Africa, Persia, and India in the northern hemisphere, and the Cape of Good Hope and Australia in the southern. The berries of various species are violent purgatives; they also yield a dye varying in tint from yellow to green. The fruit of *Zizyphus*, on the other hand, is wholesome and pleasant to eat. See BUCKTHORN, FRENCH BERRIES, JUJUBE, LOTUS, RED-ROOT, SANDAL-WOOD.

Rhapsodists (Gr. *rhapsodos*, from *rhapto*, 'I stitch together,' and *odē*, 'a song,') were the wandering minstrels of Greece who sang the Homeric poems. They were of particular importance before these poems were committed to writing. It is said that they were clothed in red while singing the *Iliad*, and in blue when singing the *Odyssey*. See Grote's *History of Greece*, vol. ii.

Rhe'a, according to Hesiod, was the daughter of Uranus and Gæa, and wife of Kronos, by whom she bore Hestia, Demeter, Hera, Hades, and Poseidon, all of whom her husband swallowed. Shortly before the birth of Zeus she repaired to her parents, who sent her to the Cretan Lyctus, where Zeus, like Krishna and Mithras, was born in a cave called by Apollodorus the cave of Dictæ, and entrusted to the Idæan Dactyli. The Indian story of Devaki and Kamsa is similar to this. R. corresponded to the Ops of the Romans, the wife of Saturn and mother of Jupiter. Her worship extended E. to the Euphrates, and even to Bactriana, her common designations among the Greeks being 'the great mother,' 'the mother of the gods,' 'the great Idæan mother of the gods,' Cybele, Dindymene, Berecynthia, &c. 'Throughout R. remained a name and a power, worshipped as the great reproductive force of the world, as producing life through death, and thus as honoured by the sacrifice of the reproductive power in her ministers.' See Cox, *Aryan Mythology*.

Rhee'a, or **Rameh Fibre**, is the inner bark of the young shoots of *Boehmeria nivea*, a plant of the nettle tribe, indigenous and cultivated in China, Japan, and the Indian Archipelago, also in Assam and various parts of India. It has lately been introduced into Réunion, Guadeloupe, and other French settlements. R. F. is one of the best fibres produced by the vegetable kingdom, being soft, fine, with a beautiful silky gloss, and at the same time exceedingly strong. The exquisite textures known as China-grass cloth are made of it. It was brought to European notice at the beginning of this century, contemporaneously with jute, but the reason why the consumption remains on such a limited scale, whilst that of jute has risen to such importance, is that the rhea is difficult to prepare, and that for growth the plant requires rich soil and continuous moisture. The government of India are at present (1878) offering a prize of 50,000 rupees for the best process of separating the R. F.

Rheims, or **Reims**, one of the oldest and most interesting towns of France, department of Marne, on the Vesle and the canal of the Aisne-à-la-Marne, 107 miles E.N.E. of Paris by rail. It is delightfully situated amid vine-clad hills, and its fortifications have been partly converted into beautiful promenades. There are many interesting buildings, but by far the most famous is the cathedral of Notre-Dame, one of the richest Gothic structures in France. It is built of the chalk-stone of the district, and dates from 1212-41, although its magnificent western façade, and its towers, 292 feet high, were not finished till 1430. The façade, nobly proportioned and royally ornate, may be said to be populous with statues, of which there are upwards of 160, comprising 42 figures of kings from Hlodwig to Charles VI. The building is 466 feet long by 99 broad, while the height of the transept is 144 feet. It has a grand rose window, several rare Italian pictures, fine bas-reliefs (especially on the Cénotaphe of Jovinus), an exquisite font, and a celebrated organ of 53 registers. In 1876 the minister of public works authorised the expenditure on the restoration of the cathedral of £80,000. Other notable buildings are the church of Saint-Rémy, 'the mickle minster of R.' (Freeman), a Romanesque

structure of the 11th c., 'where the ambassadors of England met Pope and Cæsar at its hallowing' (Freeman), the Hôtel de Ville of the 17th c. with its elegant campanile, the archiepiscopal palace, which has a beautiful Gothic chapel, and the Gothic Hôtel-Dieu. The university founded in 1547 was abolished in 1793. R. is a centre of the woollen industry, and the wine trade, manufacturing Champagne to the yearly value of 65,000,000 francs; machinery, cottons, silks, mixed fabric known as *articles de Reims*, soap, &c. Pop. (1876) 81,328. R. was called *Durocor-torum* in Cæsar's time, and was the capital of the Remi (*Civitas Remorum*), from whom it subsequently took its name. The town and neighbourhood are still rich in Roman remains. At R. the Bishop Nicasius suffered martyrdom in 406, and Hlodwig was baptized by St. Remy in 496. R. was made the seat of an archbishop in the 8th c., and from the 12th c. down to the time of Charles X. the kings of France were crowned here. Napoleon gained a victory over the Russians under Saint-Priest at R., 13th March 1814. During the Franco-Prussian War (1870) it was for some time the headquarters of the Germans. See Justinus (Baron J. Taylor), *R., la Ville des Sarres* (1860), and Marguet and Dauphinot, *Trésor de la Cathédrale de R.* (Par. 1867).

Rhein'gau, the principal district for the production of fine Rhine wines, in the Prussian province of Hesse-Nassau, extends along the right bank of the Rhine, and is protected on the N. by the Rheingaugebirge, an offset of the Taunus. It is 15 miles long and 6 broad, and includes Erbach, Rudesheim, and Johannisberg. The finest wine is produced in the vineyards of the Schloss Johannisberg, only 40 acres in extent, while Hockheim, on the Main, also yields a superior quality which has given the name of 'Hock' to the wine of the country generally.

Rhein-Hessen. See HESSEN-DARMSTADT.

Rheinpreuss'en, or **Rheinland**, the most westerly province of Prussia, bounded N. by the Netherlands, E. by Westfalen, Hesse-Nassau, and by Rhein-Hessen, S. by Rheinbayern and Elsass-Lothringen, W. by Luxembourg, Belgium, and the Netherlands. Area, 10,366 sq. miles; pop. (1878) 3,807,120. The N. part of R. is flat; the S., as far as Bonn, hilly, but nowhere reaching 3000 feet. The Rhine flows through R. in a N.N.W. direction for a length of 198 miles (its windings included), receiving from the right the Sieg, Wipper, Ruhr, and Lippe; and from the left the Nahe, Moselle, Ahr, and Erft. 31 per cent. of the surface is forest, and 14 per cent. waste land. The rest is fertile and well cultivated. In 1873 there were in R. 134,256 horses. Vineyards abound on the Moselle, Rhine, and Ahr. R. has rich mines of iron, coal, lead, and zinc. The industries include the manufacture of iron, steel, and brass goods, paper, leather, chemicals, porcelains, cottons, and silks. Of the population of R., 70 per cent. are Catholics, 20 per cent. Protestants. There are also 60,000 Jews and 4000 Mennonites.

Rhesus Monk'ey (*Macacus rhesus*), a *Catarrhine* or Old World monkey, also known as the Bhunder monkey, inhabiting E. Asia. The fur shows greenish tints, washed with warm chestnut hues. The body is stout and the tail short. The ears are prominent, and the natal callosities (or bare hip-patches) are very conspicuous. The R. M., which is held sacred in India, herds in large troops in the forests, and makes great devastation of the grain crops.

Rhet'oric (Gr. *rhētorikē technē*, 'the rhetorical art,' from *rhētōr*, 'an orator') is the art of prose composition. Aristotle's definition of it as the art of persuading, when applied to written as well as spoken discourses, is still sufficient to embrace the various parts of R. Aristotle's divisions of it were three;—Persuasion (*piſtis*), Expression (*lexis*), and Arrangement (*taxis*). The R. of Aristotle is still the standard work on the subject; Cicero, and later, Quintilian, devoted considerable pains to its elucidation, and in modern times Blair and Whately have been as successful as any others in treating it systematically.

Rheum'atism (Gr. *rheuma*, 'a flux,' from *rhēō*, 'I flow') is a disease arising from some disordered or abnormal condition of the blood, the most marked characteristic of which is its predisposition for the white fibrous tissue which enters into the composition of sheaths, fascia, fibro-serous membranes and ligaments, and thus, in particular, affecting the joints. The heart and its membranes are often implicated. The late Dr. Prout first pointed out that the blood, in cases of R., contained a superabundance of lactic acid, and he considered this acid to be the actual *materies*

morbis of the disease. Dr. Richardson found that, by the injection of 7 drachms of lactic acid to 2 ounces of water into the peritoneum of a cat, endocardial inflammation, especially of the left side of the heart, and fibrous deposits on the mitral and aortic valves, were produced, but peritoneal inflammation was not induced. In cases of R. the lactic acid is supposed to be formed in the pulmonary circuit of the blood, and from thence carried into the left ventricle, to be propagated by the general circulation to the parts where the disease is manifested. The fibrine appears to preponderate over the saline constituents of the blood during the disease. R. is most commonly divided into *acute* and *chronic*; but there is no distinct line of demarcation between the two, and the latter is frequently a consequence of the former. In acute R. the general and local symptoms are well marked. There is usually a feeling of coldness, want of appetite, thirst, and more or less feverishness, accompanied by acute local symptoms, as redness, heat, swelling, and usually very intense pain in one or more joints. The large joints are often implicated, but the middle-sized ones, as the knee, ankle, wrist, and elbow, are more usually attacked. The disease tends to shift from one joint to another, and does not often remain fixed in the one first affected; and it has been found that, in three cases out of four of acute articular R., with high fever, the heart is affected with endocarditis, or endopericarditis, and the foundation is laid for permanent chronic valvular disease. The implication of the heart is insidious, and being frequently attended with no pain is only discovered on examination with the stethoscope. When R. is thoroughly established the pain is severe, and is intensified by the slightest movement. The pulse is full and quick, there is headache but seldom delirium, the tongue is covered with a creamy thick fur, the tip and edges being red; and the fever is attended with a peculiar acrid, copious, and sour-smelling sweat. The bowels are generally constipated; urine is high coloured and scanty, and deposits, on cooling, a quantity of urates. The temperature ranges from 100° to 104°, gradually ascending for at least a week, but subject to considerable variations, sometimes reaching as high as 108° or 109° in fatal cases. The duration of an attack varies from three to six weeks, but it may extend over several months, and relapses are common. R. is not a very fatal disease, deaths being in the ratio of about 1 in 1000, but it is frequently a serious disease in the after-mischief which it entails by cardiac and other complications. If the effects of R. were taken into account, it is probable that instead of occupying about the thirty-fourth place in diseases, arranged according to their fatality, it would rank tenth or eleventh, for at least two-thirds of cardiac diseases are due either directly or indirectly to R. or its ally, gout. Although the termination is generally in recovery, the joints are frequently left stiff, or they may become chronically enlarged.

The chief exciting cause of acute R. is exposure to cold combined with moisture, sleeping in damp sheets, the wearing of wet clothes, living in a damp house, and more particularly in a newly built house which has not been thoroughly dried. Badly drained houses are prolific causes of R., more especially when the foundation is laid on a sub-soil retentive of moisture, as the moisture constantly passes up and saturates the walls. By the action of the cold and damp, the excreting power of the skin is checked, and certain effete matters which should be eliminated by the process of insensible perspiration are retained, and give rise to blood-poisoning. R. is a great cause of invaliding both in the army and navy, and is most prevalent in climates which are remarkable for damp and variable weather.

Proper drainage of the ground, and strict care that no house has damp foundations, may do much to prevent R. All persons subject to R. in any form should wear flannels in the winter, and clothe lightly in the summer, instead of wearing almost the same underclothing in both the hot and the cold season. The safest plan is always to wear flannel or woollen material next the skin, but of a lighter texture during the summer season.

Treatment.—Bleeding and the administration of mercury and purgatives were formerly the usual modes of treatment, but these are now practically abandoned, and the alkaline treatment, or the administration of salicin, is generally adopted. Two scruples of the bicarbonate of potass and soda may be given every three or four hours in half a bottle of soda water, and should be continued steadily until the febrile disturbance is lessened, the pulse reduced, and the urine rendered alkaline. Flannels soaked in an alkaline lotion consisting of half an ounce of carbonate of soda, and six drachms of Liq. Opii, added to nine ounces of hot

water, should, after being wrung out, be applied to the affected joints, and gutta-percha tissue should be placed over all. Milk diet and farinaceous food should be given at first, and afterwards beef-tea and nutrient and easily assimilated food. Salicin, as recently recommended by Dr. MacLagan, is said to be highly beneficial in the treatment of acute R. When administered in fifteen-grain doses every two hours, it lowers the temperature and diminishes the duration of the disease; indeed, salicin is confidently stated to be a specific in cases of acute R. Salicylic acid, a much cheaper preparation, is said to be equally efficacious, and it may be given in combination with acetate of potass.

Gonorrhoeal R., or synovitis, is a painful and often a very intractable disease, supposed by some to be a form of pyæmia or blood-poisoning, the starting-point of which is inflammation of the veins around the urethra or prostate gland. It has been observed that the R. persists as long as the gonorrhoeal discharge continues, and even so long as there is any tenderness in the affected portion of the urethra, but subsides when the urethra has become perfectly healthy. R. sometimes occurs, though rarely, after urethritis from other causes. In such cases the knee-joint is generally the principal seat of the disease, but other joints may also be implicated, and there is considerable synovial effusion. The pain is not usually acute, but it is constant and more severe at night.

Rheydt, a town in Rhenish Prussia, on the left bank of the Niers, an affluent of the Maas, 17 miles W.S.W. of Dusseldorf by rail. It manufactures silks, velvets, yarn, hosiery, shawls, linens, leather, soap, glue, paper, and vinegar. Pop. (1875) 15,857.

Rhin Bas and **Rhin Haut**, formerly departments of France, now included in the Germanic territory of Elsass-Lothringen. See ALSACE-LORRAINE.

Rhinanthus is a small genus of *Scrophulariaceæ*, consisting of erect annual herbs, which are supposed to have a parasitic connection with roots of the grasses, &c., amongst which they grow. The flowers are yellow, spotted with purple, and are arranged in one-sided spikes. When the seed is ripe, it rattles inside the compressed membranous-valved capsule, thereby procuring the name of 'yellow-rattle' for the common British species of pastures and grassy wastes. The name R. is derived from the Greek for 'nose' and 'flower,' in allusion to the form of the corolla. The species are confined to the northern hemisphere.

Rhine (anc. *Rhenus*, Ger. *Rhein*, Fr. *Rhin*, Dutch, *Rijn* or *Rijne*), one of the most famous rivers in Europe, no less as a centre of art and legend than on account of the singular beauty of its scenery and its great material prosperity. It rises in Switzerland, and is formed at Reichenau, in the canton of Grisons, at an elevation of 1922 feet, by the confluence of two streams, the Vorder and Hinter Rhein, the former of which, rising on the N.E. side of St. Gothard, and receiving the small Mittler Rhein, is generally regarded as the principal source of the river. While, however, the latter is only 50 miles long, the Hinter Rhein is 80 from its sources in the glaciers of Vogelberg to the point of confluence. Immediately below the Reichenau, where it takes its general name, the river is navigable for rafts and small craft; but throughout its whole upper course as far as Basel its navigation is difficult, and in many places entirely interrupted by rapids and cataracts, of which the Falls of Schaffhausen, where the water suddenly leaps from a rock 70 feet high, is the most remarkable. At first with a northerly course the R. flows through the romantic valleys of the Grisons, St. Gall, and Voralberg, till it reaches the Lake of Constance (Boden-See), from which it takes a westerly direction, forming the boundary between Switzerland and Baden. At Basel it turns suddenly N., becoming a purely German river, and flowing through the broad, beautiful Rheintal, often called the garden of Germany, between the Schwarzwald and the Vosges. After receiving the Main at Mainz, it swerves to the W. and N.W. as far as Bonn, passes through the loveliest scenery of its course, dominated by many towering castle-crowned rocks, and hemmed in by steep, vine-clad hills, opening in fair valleys, which send down rushing streams. The river here has a rapid current and a most sinuous course, and its navigation is rendered intricate by numerous islands and shifting sandbanks. Its lower course, which zigzags as far as the German frontier, leads from Köln to the

North Sea through low, level, uninteresting country. In the Netherlands it branches off into the Waal, Yssel, Leek, and Vecht, and so reaches the ocean in a number of small streams, which lose much of their volume among the sandbanks of the shore. The entire length of the R. is 960 miles; its breadth at Basel is 189 yards, at Mannheim 429, at Mainz 492, at Koblenz 399, at Bonn 532, at Köln 433, at Düsseldorf 403, and 909 at the Dutch frontier. Its greatest depth between Mainz and Bonn is 76 feet, and its chief affluents are the Aar in Switzerland, the Neckar and Main in the Rheintal, and the Lahn and Moselle in the highlands of its lower course. The delta, comprising an area of 50,000 sq. miles, is intersected by a network of canals, and is protected by extensive embankments. Canals connect the R. with the Rhone and Saône, the Scheldt, Maas, and Danube. It is the channel of a great trade in timber, coal, iron, wine, colonial produce, and manufactured goods. Its banks are now lined with railways, and more than 100 steamers ply on the river, conveying annually as many as a million passengers. In the basin of the R. the winter usually lasts from six to eight weeks, during which time the river is sheeted with ice, and snow accumulates in the adjacent country. In the event of a sudden thaw the river swells to an extraordinary height and inundates the contiguous lowlands. The *Betuwe* ('good meadow land;,' Lat. *Batavia*), the tract lying between the R. and Leek on the N. and the Waal on the S., is particularly liable to destructive flooding.

The R. was anciently one of the longest and most important natural boundaries of the Roman Empire, and across it the Franks, Burgundians, Suevi, and Vandals forced their way to find new homes in the plains of Gaul and Hispania. It is intimately associated with the great literature of German legend and lyric. Its waters were denized with the weird race of the Nibelungen, and the hero of the Nibelungen Lied slew on its banks the monster of the Drachenfels (q. v.). The Lorelei (q. v.) is perhaps the most beautiful of all Rhenish legends. See, besides the excellent guide-books of Badeker, Berlepsch, &c., Simrock's *Das Malerische und Romantische Rheinland* (4th ed. 1865), Kohl's *Der Rhein* (2 vols. Leips. 1851), Müller von Königswinter's *Rheinfahrt* (Frankf. 1846), and *Der Rhein* by Stieler, Wachenhusen, and Hacklander, with 420 drawings on wood by German artists (Eng. trans. Lond. 1877).

Rhine, Confederation of the. See CONFEDERATION OF THE RHINE.

Rhine Wines constitute a class of beverages distinct in character from the wines of all other districts. They are generous full-bodied wines, that improve with age in an unexampled manner. The most characteristic varieties are white, and embrace Liebfraumilch, Johannisberg, Steinberg, Nierstein, Marco-brunner, Rüdesheimer, and Hochheimer, the latter being the Hock of Great Britain, under which name indeed the R. W. are generally drunk in this country. Hock and other R. W. are prepared either as still or sparkling (effervescent) wines. The red wines of the Rhine are not of equal fame, but Asmannshäuser is rising in favour.

Rhinns of Galloway. See WIGTOWNSHIRE.

Rhino'ceros (*Rhinoceros*), a genus of *Ungulate* or hoofed quadrupeds, deriving its name from the development on the nasal bones of one or more hard epidermal growths or 'horns,' which, however, are merely bundles of modified hairs. The R. is one of the *Perissodactyla*, or 'odd-toed' Ungulata. There is but one genus, numbering several species, included in a distinct family (*Rhinocerotidae*). The family characters are derived from the large size of these animals, from their thick skin, which is usually thrown into massive folds, from the blunt and rounded muzzle, and from the absence of canine teeth. Incisors are present in both jaws, and the molars number fourteen in each. The skull is pyramidal, and when more than one horn is developed the hinder horn is borne by the frontal bones, and is placed behind the front horn in the middle line of the head. The latter is the larger. The R. formerly had a much wider geographical distribution than at present. It is now confined to Africa and Asia, each continent having distinct species. The most familiar forms are the Indian R. (*R. Indicus* or *unicornis*) and the Javanese R. (*R. Sondaicus*) of Java, Sumatra, and Borneo, both having one horn. The *R. Sumatrensis* of Sumatra has two, as has also the African R., *Rhisaster* or *Boreale* (R.

Africanus or *bicornis*). Another African form is the *R. Simus*, or white R. The Asiatic species have the skin-folds more definitely marked than the African forms. The Indian R. attains a height of 5 feet, and is of a deep brownish black. The R. is harmless, but somewhat irritable and uncertain in temper. The Javanese R. is smaller than the preceding. The white R. of Africa is one of the largest species, its front horn being very long. The flesh is valued by the natives, and is said to be highly palatable. A species named the Kobaoba, or long-horned white R. (*R. Osmellii*), is of rarer occurrence than the white R. The front horn exceeds 4 feet in length. Fossil species of R. occur first in the Miocene rocks. One celebrated extinct species is the *R. tichorhinus*, or woolly-haired R., which inhabited England and Europe generally. It occurs first in the *Preglacial* deposits of the Thames valley, and its remains are found in cave-deposits and valley-gravels. Other fossil species are the *R. Etruscus*, *hamitachu*, *incisivius*, *megarhinus*, &c.

Rhinoplastic Operation. This operation is occasionally resorted to when a portion or the whole of a nose has been destroyed by accident or lost by lupus or syphilis; but it does not find much favour with surgeons of the present day, as the new nose being formed only of skin, generally either withers away or remains flat on the face, and in either case the appearance of the patient is not much improved. Another objection is, that the flap being usually taken from the forehead, another scar is added to the previous deformity. The operation is described by Mr. Holmes as follows:—‘The common plan, or the Indian operation, is to take a piece of paper, gutta-percha, or leather, and adapt it to the stump of the nose, so as to form as shapely a feature as may be; then lay the pattern on the forehead, and cut a flap of skin accordingly, leaving it attached by as broad a neck as possible to the bridge of the nose. A little tongue is left on the middle of what was the upper border of the flap, and which when it is twisted becomes the lower, in order to form the columella. The edges of the cliff should be refreshed before cutting the flap, and the latter brought down and attached as rapidly as possible in its new position by several points of silver suture. The new nose must be supported in position by a plug, or two plugs, of suitable size and shape, and of some non-absorbing material, and supported on the plug by a pad and bandage loosely applied. When the union of the edges is complete, and the transplanted flap perfectly warm and full, the neck may be divided, the rest of the cleft over the bridge of the nose pared, and the raw surface left by the division of the neck implanted there.’

The R. O. was first performed by Taliacotius, professor of anatomy and surgery at Bologna, where he died in 1553, and is popularly known as the *Taliacotian Operation*. The flap, instead of being taken from the forehead, was transplanted from the patient's arm. The restrained position, however, is a great objection, as an apparatus must be adapted which will keep the arm in comfortable apposition with the face. Dr. Hardie, of Manchester, has transplanted the distal phalanx of one of the fingers into the nose in order to provide a long base for the transplanted flaps. Dr. Wolfe of Glasgow asserts that the skin may be simply cut from the arm, or other part, and inserted into the face where it will adhere and grow.

Rhizan'thesæ (Gr. ‘root’ and ‘flower’) was a natural order established by Blume (1828) to include the parasitical plants divided by modern systematists into the *Balanophora*, the *Cisturape*, and the *Rafflesia* families. Lindley made a separate class of this group under the name of *Rhizanthus*, and placed the same in his arrangement between the endogens and the acrogens. He says:—‘In their succulent texture, in their colour, often in their putrid odour when decaying, in the sporeiferous seeds, in their parasitical habits, these plants resemble *Fungaceæ*; while in their flowers and their sexes they accord with *Araceæ* or similar endogens.’ Bentham and Hooker combine them in two orders—*Balanophoraceæ* and *Rafflesiaceæ*, which are respectively included in the cohorts *Santalales* and *Asarales* of the subdivision of apetalous dicotyledons with an inferior ovary. Taking the three families above mentioned—(1) *Balanophoraceæ* are found chiefly in the Himalaya and Andes. Some of the species are astringent, and have been employed as styptics, e.g., the *Cynomorium coccineum*, commonly known as *Fungus melitensis*, which grows in Malta and Sardinia. *Balanophora elongata* furnishes a wax much used in Java for making candles, and various N. Indian

species of this genus form large knots on the roots of the oaks and maples upon which they grow; these excrescences are much prized for manufacture into the cups in general use in the Himalaya and Thibet. (2) *Cytinaceæ* are root-parasites met with in S. Africa and the Mediterranean region; they also, from the presence of gallic acid, are serviceable as astringents and styptics, and include the *Hydnora Africana* or ‘jackal's kost,’ which is eaten, when roasted, by the African savages. For (3) *Rafflesiaceæ*, see article *RAFFLESIA*. The total number of known species belonging to this curious group is about 60, in 23 genera.

Rhizocrinus, a genus of *Crinoids* or Lily Stars, represented by the *R. Lofotensis*, observed by Sars of Christiania in 1867 in the North Sea off the Loffoden Isles. The interest attaching to this form arises from its forming the existing representative of an interesting fossil family (*Apicrinidae*) of ‘Pear encrinites;’ the group, prior to the discovery of R., having been regarded as extinct. R. is permanently rooted to the sea-bed, and has a flexible jointed stem, destitute of branches save at its root-extremity. The arms are furnished with *pinnules* or branches, and the *calyx* or body-cup is well developed.

Rhizophoraceæ, an order of polypetalous dicotyledons, consisting of tropical trees or shrubs with opposite entire leaves, and axillary flowers either single or in clusters. The stamens are sometimes twice as numerous as the petals. The ovary has two or more cells, and the fruit has few seeds. The order includes some fourteen genera variously found in the continents of Asia, Africa, and America.

Rhizopoda (Gr. *rhiza*, ‘a root,’ and *pous-podos*, ‘a foot’), a class of *Protozoa* (q. v.), distinguished primarily by the fact that the soft protoplasm or living matter of their bodies can be protruded to form processes or *pseudopodia*, adapted for locomotion and prehension. No mouth exists, and a *nucleus* and *nucleolus* are present in the majority of R. The pseudopodia may be blunt, finger-shaped processes as in *Amaba*, or delicate and interlacing as in *Foraminifera* (q. v.). Included in the group R. are several orders. Of these latter, the (1) *Monera* include organisms regarded as the lowest R. They are minute in size, and occur in the sea. Their bodies are circular, and capable of protruding pseudopodia, which usually form a radiating series of processes. The *Monera* do not develop any test or hard structures, and they reproduce their like chiefly by *fission* (see *REPRODUCTION*), and usually without encystation. No nucleus exists. *Protomyxa* is a familiar genus. The (2) *Amabina* form the second order of R., and are represented by the various species of *Amaba*—the ‘Proteus-animalcules’ of older naturalists. The *Amabæ* occur in stagnant water, and in infusions of organic matter. They have a nucleus, nucleolus, and contractile vesicles, the latter being small clear spaces, which contract and expand rhythmically. Their pseudopodia are blunt and finger-like, and do not interlace. With one or two exceptions the *Amabina* have no hard parts. One genus (*Diffugia*) makes itself a covering of sandy particles, named a *carapace*. *Arvela* has a discoid carapace; and *Actinophrys sol*, the ‘Sun Animalcule’—another of the *Amabina*—has merely a tough outer layer (*ectosarc*) of the body, from which numerous stiff radiating filaments proceed. The third and fourth orders of R. are the (3) *Foraminifera*, and (4) *Radiolaria*, both of which are noticed in detail in the articles under these names.

Rhode Island, the smallest State in the American Union, one of the original thirteen. It belongs to the New England group, and is bounded on the S. by the Atlantic, on the W. by Connecticut, and on the N. and E. by Massachusetts. Its area, including the waters of Narragansett Bay, 30 miles long, which divides it into two unequal portions, is 1306 sq. miles, but its land surface is not more than 1054 sq. miles. Pop. (1875) 258,239.—The State takes its name from an island (Dutch *Rode Eylant*, ‘red island’) in Narragansett Bay, on which is situated the town of Newport, one of the capitals, the other, Providence, being situated on the mainland, on the Providence River. The other chief towns are Pawtucket, Woonsocket, Warwick, Lincoln, and Bristol. Its direct shoreline is only 45 miles, but owing to its sinuosities, its whole coast-line is about 350 miles. Partly on this account the climate is milder than that of the other New England States. Except in the S.W. where there is much sand, gravel, and salt-marsh, the soil is moderately fertile, but much of it is difficult of culti-

vation owing to the rugged formation of the country. In 1870 289,030 acres were under cultivation, while 213,278 acres were in wood-land or other unimproved farm-land. The aggregate value of crops in 1875 was \$3,316,228, among the items being Indian corn \$281,000, rye \$21,000, oats \$145,000, barley \$25,500, and potatoes \$560,000. Of live stock the total value was \$3,673,485, the items being 14,700 horses, 36,400 cattle, 25,300 sheep, and 16,500 pigs. The geological formation of the western half of R. I. is Eozoic, but the remainder is Carboniferous. About 15,000 tons of anthracite coal are annually mined, and iron, limestone, sandstone, and marble are also worked. R. I. has more manufactures in proportion to its area and population than any other State, though it only ranks tenth among the States in absolute amount of manufactured products. In 1870 it contained 1850 manufactories employing 49,417 hands; the capital invested was \$66,557,322, and the produce of that year was estimated at \$111,418,354. Cotton, woollen, and worsted manufactures employed 315 establishments, and produced nearly \$75,000,000. The other manufactures are principally hardware, jewellery, india-rubber goods, and clothing. In 1876 there were 220 miles of railroad in the State.

R. I. is supposed to be the Vinland discovered by the Scandinavians in the 10th c. The present state was founded by Roger Williams, a distinguished divine of Salem, who was driven from his charge in 1636 by the intolerance of the 'Puritan fathers,' on account of his Anabaptist opinions. After six weeks of extreme hardship, he landed in the early spring of 1635 on the present site of Providence. Two years later he was joined by his friend William Coddington, and the colony began to increase. In 1663 Roger Williams gained for it a very liberal charter from Charles II., under which it was governed, both as colony and State, until 1842. It was noted for the toleration with which religious opinions were treated within its bounds, contrasting in this respect with other New England colonies. It took a prominent part in the War of Independence, and for some time after its close Newport contended with New York and Boston for the commercial supremacy of the new republic. In 1842, after a severe political struggle, the old charter was replaced by a new constitution. R. I. took an active part in the Civil War on the Federal side. See *A Short History of R. I.* by G. W. Greene, LL.D. (Lond. 1877).

Rhodes (Gr. *Rhodos*), a Turkish island in the Mediterranean, 10 miles off the S.W. coast of Asia Minor. Length, 45 miles; breadth, 20 to 25 miles. Pop. 34,000 (24,000 Greeks, 7000 Turks, and 2000 Jews). The surface is mountainous, culminating in Attairo (anc. *Atatyris*), 4560 feet high. R. is throughout volcanic. The climate is proverbially fine, and the rich soil produces abundant wine, oil, wheat, and southern fruits.—**R.**, or **Kastro**, the capital, on the N.E. point of the island, has a fortified harbour with a narrow entrance. Its streets are dark and narrow. The best parts are the Jews' quarter, with a synagogue, and the suburb Neomaras, inhabited by the European merchants and consuls. R. is the seat of a pasha and of a Greek archbishop, has an arsenal and dock (where two schooners of 100 and 120 tons were built in 1876), and is an important station for the Turkish fleet. It is also a station for the steamships between Constantinople and Asia Minor and Alexandria. The trade of R. is chiefly transit, and carried on by steamers. In 1876 there entered and cleared the port 1088 vessels (66 English) of 288,511 tons. The exports, chiefly sponges (£140,000 in 1876), sesame seed, valonea, onions, wax, wine, storax, oil, fruits, amounted to £824,920; and the imports, mainly cottons, silks, woollens, coffee, sugar, leather, metals, rice, petroleum, soap, saltfish, to £167,400. In 1870 R. was connected by submarine cable with Asia Minor, Candia, and Alexandria. The town has suffered much from earthquakes (1851, 1856, and 1863), and from a great gunpowder explosion in 1856. R. was founded in 408 B.C. In ancient times it had great trade, and was equally famous for shipbuilding and the manufacture of arms and engines of war. The Athenian Æschines founded at R. a famous school of oratory, as afterwards did Apollonios Molon, among whose disciples were Cicero and Cæsar. Near the entrance to a harbour now nearly sanded up Chares erected (270 B.C.) the celebrated Colossus (q. v.). It was overthrown by the earthquake of 222 B.C., and is said to have been set up again, yet it lay in ruins in 672 A.D., when the metal (900 camel loads) was sold by the Kalif Moawiya I. to a Jew. Its

naval power was greatest at the time of Alexander the Great, when it was the head of a sort of Greek Hansa, and established for the first time a generally accepted code of law for trade and naval affairs, which was powerfully exerted against piracy. R. successfully resisted Demetrius Poliorcetes in 364 B.C. In the civil wars it joined the party of Cæsar, and after his death suffered much from its resistance to Cassius (42 B.C.). It never recovered its power, though it was long afterwards celebrated as a seat of learning. It was unsuccessfully besieged by Mohammed II. in 1480, when it was defended by the grandmaster Pierre d'Aubusson; but in 1522 it was taken by Suleiman II., after a heroic defence by the knights of St. John under Villiers de l'Isle Adam. On the 1st January 1523 the knights left the island (which they had occupied from 1309). It has ever since been held by Turkey. See Ross, *Reisen nach Koss, Halikarnassos, Rhodus und Cypern* (Halle, 1852); Guérin, *Voyage dans l'île de R.* (Par. 1856); and Berg, *Die Insel Rhodus* (Brunsw. 1861).

Rho'dez, the chief town of the department Aveyron, France, on the steep N. bank of the river Aveyron, 80 miles N.E. of Toulouse, with which it is directly connected by rail. Its cathedral is one of the finest Gothic structures in the S. of France, dating from the 13th and 14th centuries, having a lofty tower and magnificent stained glass windows. R. has several other interesting buildings, and is rich in Roman remains. Its manufactures are woollens, serges, leather, paper, playing-cards, &c., and its trade is chiefly in cattle, horses, and cheese (*fromages du Cantal*). Pop. (1872) 12,111. Anciently *Segodunum*, the chief town of the Celtic *Ruteni*, R. was in the Middle Ages, as *Rutena*, capital of the *Pagus Rutenicus*, and later, that of the principality of Rovergue (*Comitatus Rodensis*). After varying fortune, it passed by marriage to Henri III. in 1526.

• **Rho'dium** (Ro = 104.3), one of the platinum group of metals, forms usually about one half per cent. of the platinum ore, from which it is obtained after a lengthened and complicated process in the form of a double chloride of R. and sodium. By heating in hydrogen the R. is reduced to the metallic state, and after the chloride of sodium has been washed out with water, is left as a grey powder. The metal is hard and malleable, less fusible than platinum, and insoluble even in *aqua regia* except when alloyed with other metals. It forms two oxides, two sulphides, and three chlorides. The terchloride (RoCl₃), itself non-crystallisable, forms beautiful crystallisable double salts with the alkaline chlorides. Most of its salts are a beautiful red colour, whence the name of the metal. It was discovered by Wollaston in 1803.

Rhododen'dron (Gr. 'rose-tree') is a genus of *Ericacea*, consisting of shrubs or trees with entire alternate leaves and large showy flowers, usually in compact terminal clusters or umbelliferous corymbs, from large buds with scaly bracts. The corolla is funnel-shaped or campanulate, five to twelve lobed, and sometimes slightly irregular. The stamens are from ten to twenty, commonly declining, as well as the style; the anthers short, opening by pores; the ovary is superior; the capsule cylindrical, dehiscent septically; the seeds numerous and scale-like. The genus R. is widely diffused, having its headquarters in the temperate parts of N. America and the mountains of India. In the size attained by the species there is a great contrast, ranging from the Arctic *R. Lappo-nicum*, a prostrate shrub with branches a few inches long, to Indian trees of a height of 50 to 60 feet and a girth of upwards of 15 feet. The kinds commonly grown in Britain in gardens, shrubberies, and game plantations, are chiefly varieties of *R. ponticum*, a species found wild on the coasts of the Black Sea, from the range of Caucasus through Armenia and Georgia to the western frontier of Persia; or of *R. catawbiense*, an American species; or hybrids between these. *R. arborum*, known as the Tree K., and common on the outer ranges of the Himalaya from the Indus to Bhutan, is hardy in S. England in sheltered places. The flower-buds and young leaves are believed to be poisonous to cattle; the flowers, however, are eaten in India by the natives, and are made into a pleasant sub-acid jelly by European residents. *R. campanulatum*, also from the Himalaya region, between 9000 and 14,000 feet, is hardy in Britain, and is commonly grown in gardens. The dense buff-coloured coating of the under-surface of the leaves is used as snuff. *R. anthopogon*,

from the same district, is half-hardy. The leaves are used as a stimulant in native medicine. The wood of *R. maximum*, a native of N.E. America, is said to be equalled only by the best boxwood for engraving purposes. The discoveries of Dr., now Sir J. D. Hooker, during his exploration of Sikkim, added greatly to our knowledge of *R.*, and since the publication of his magnificent work devoted to the subject (*The R. of Sikkim Himalaya*, 1849), the genus has been held in high esteem by cultivators, who have raised numberless varieties and hybrids. The beautiful *R. Dalhousia*, which was one of Dr. Hooker's discoveries, is remarkable as being an epiphyte; and *R. nivale* was found by him flourishing at the immense height of 17,000 feet; it is the most alpine of woody plants. *R. ferrugineum* and *R. hirsutum* are two small species, with carmine-coloured flowers, found in the European Alps, and *R. chrysanthum*, with yellow flowers, is a native of Siberia. The leaves of the last named have a great reputation for chronic rheumatism.

Rhombus is a Parallelogram (q. v.) whose sides are all equal, but whose angles are not right angles.

Rhone (Lat. *Rhodanus*), next to the Loire the largest river of France, and the swiftest in Europe, rises on the W. side of Mount St. Gothard, at the foot of Maienwand, at a height of 5468 feet above the sea. It runs through the canton of Valais, and after receiving the Drance, turns to the N.W. and enters the Lake of Geneva, issuing from its S.W. extremity in a clear blue stream, which, however, is soon defiled by the muddy waters of the Arve. It next flows S.W. through a rocky gorge of Mount Jura, and near Fort de l'Ecluse, when the water is low, disappears altogether for 300 feet in the so-called *Perte du R.*, a cleft of the rock which has recently been considerably widened. After flowing S. for several miles, it turns sharply to the W., until it is joined by the Saône at Lyon, after which it is navigable and flows S., passing the towns of Vienne, Tournon, Valence, Avignon, and Arles, and receiving on the right the Gier, Ardèche, and Gard, and on the left the Isère, Drôme, and Durance. It empties itself into the Mediterranean. About half a mile above Arles, the R. divides into two arms, which again divide into others, and which are called the Greater and the Lesser R. They enclose the delta known as the Ile de la Camargue. The length of the R. in a direct line is 276 miles, that of the stream 506 miles, and with all its windings 644 miles. Its drainage area is 28,000 sq. miles, 3080 sq. miles of which belong to Switzerland. Its breadth at Valence is 2200 feet, at Arles 5220 feet. The R. carries into the sea 88,000 gallons of water per second. Its navigation is much obstructed by the shifting sandbanks in its bed, which are most abundant near the Bouches du R.; accordingly communication with the main stream is through the L'Etang de Beire and the canals of Martigues and Beaucaire. Passing through some of the most fertile districts in France, the R. has great commercial importance, which has been greatly increased through its being united by canals with the Loire, the Seine, and the Rhine. From the comparative failure for some years past in the cultivation of the vine and madder in the R. valley, causing an annual loss of £3,200,000, public attention has been called to the necessity for providing adequate means for irrigation. A scheme which seems likely to be realised, has (1878) just been proposed for a great canal to branch off from the R. below Vienne, near Condrieu, and thence to follow the left bank of the river above Valence and Montbeliard, to cross at Mornas in large syphons to the right bank, and thence pass through Nîmes, Lunel, Montpellier, Beziers, and Narbonne. The estimated cost of construction is £4,800,000 (of the syphons alone £280,000). With a length of 310 miles, it would irrigate 543,650 acres, and offer to navigation between Condrieu and Mornas a waterway 50 feet wide and 10 feet deep, which might be extended to Marseille and the Mediterranean, and which would ensure to vessels of not more than 300 tons the traffic between Havre, Paris, and Marseille. See Lenthéric's *Villes Mortes du Golfe de Lyon* (Par. 1876).

Rhône, a department of France, second only to that of Seine in smallness and density of population, is bounded N.W. by Saône-et-Loire, E. by Ain, S.E. by Isère, and S. and W. by Loire. Area, 1077 sq. miles; pop. (1876) 705,131. The western part is covered by the northern prolongations of the Cévennes, which also send out spurs to the N.E. and S.E. R. is included in the basin of the River R., which with the Saône forms its E. boundary from 10 miles below Mâcon to Condrieu. It is well watered by their affluents. The climate is healthy, and the soil in

the vicinity of the rivers extremely fertile. Much, however, is poor, and the crops raised are not sufficient by half for the wants of the population. Excellent wines are produced, especially those of Sainte-Foy, Côte-Rôtie, and Condrieu. The mineral wealth is not great, but copper ore and coal, porphyry, granite, and marble are obtained. R. owes its importance to the vast extent and varied nature of its industries, the principal of which is the production of silk fabrics, especially at Lyon (q. v.). Cottons, muslins, calicoes, liqueurs, chemical products, paper, glass, beer, and earthenware are also largely manufactured.

Rhone, Bouches du. See BOUCHES-DU-RHONE.

Rhöngebirge, a group of volcanic hills, part of the German Mittelgebirge, to the S.W. of Thüringerwald, between the valleys of the Fulda and Werra. The principal heights are the Milseburg (2813 feet), the Pferdskopf (3100), the Wasserkuppe (3074), and the Kreuzberg (3042). Much of the group is well wooded, and the plateau of Vorderrhön, in the N., is in part cultivated.

Rhubarb (Mid. Lat. *rha*, from its Oriental name, and *barbarum*, 'foreign,' to distinguish the plant of the Volga

from the *R. Rapaonticum*, another kind from the Roman province of Pontus. Prior), known botanically as *Rheum*, is a genus of large herbaceous plants belonging to the natural order *Polygonacea* (q. v.). All the species are perennials, with large root-stocks, from which the large sheathing leaves and flower-stalks are given off. The inflorescence consists of much-branched panicles, bearing a great number of whitish, greenish, or pinkish flowers. Central Asia is the headquarters of the genus. The R. cultivated for the sake of its leaf-stalks includes several species, *R. Rapaonticum* and *R. undulatum*, with their numerous garden varieties, being most commonly grown. Although introduced into England 300 years ago, it is only within the present century that its value for culinary purposes has been recognised. It is now largely used, either made into tarts, or stewed alone, or in the form of jam. From the juice a wine is also made, and the unexpanded flower-heads are recommended for use in the same way as the leaf-stalk, whilst the leaf itself can be dressed in the same manner as spinach. This last was the only use made of R. in the time of Queen Elizabeth.

The source of the fine qualities of the R.-root used in medicine and known as Turkey R. has been enveloped in much mystery owing to the jealous reticence of the Chinese, but with the opening of Central Asia through the exertions of modern scientific travellers, the fact has been established that most of it is the produce of *R. officinale* of Baillon, and of a variety of *R. hybridum*—plants of the high tableland of Western China and Eastern Tibet. Baillon insists on the influence exercised on the quality of the drug by the method of collection, the season when it is made, whether it is taken from the lower stem portion of the plant or from the root, and probably also on the process of drying. A portion of the E. Indian R. of commerce, it has also been recently ascertained, is derived from *R. palmatum* var. *Tanguticum*, a plant of the Mongolian mountains. The Himalayan *R. Emodi* and *R. Webbiana* yield Indian R.—not, however, of much medicinal repute. The name 'Turkey R.' is a misnomer, as the import meant thereby comes from Chinese territory, and the term arose simply from the drug in former times reaching Western Europe *via* Natōka. Since the extension of Russian conquest to the Chinese boundary some has come through Russia, but no supply has been thus received for several years. R. contains Raphides (q. v.) of calcium oxalate, along with tannin, gallic acid, resin, and a peculiar yellow-coloured principle called rhabarberin. *Medicinally*, it is employed as a cathartic, astringent, and tonic, in the form of powder, pill, extract, tincture, wine, and infusion. It should not be administered in a high

Himalayan Rhubarb.

sthenic state of the system, or when depletion is necessary; but it is the best purgative when it is desired simply to unload the bowels in a debilitated subject, as in cases of diarrhoea with intestinal weakness. In the form of syrup, combined with an alkali, it is especially valuable in the summer bowel complaints of children when the stools are greenish and mucous. Powdered R. may be given in doses, as a stomachic, of from 1 to 5 grains, and as a purgative, 10 to 20 grains. The following are the pharmaceutical preparations of R. and their doses:—*Extractum R.*, 3 to 6 grains; *Infusum R.*, 1 to 2 ounces; *Pilula R. Composita*, 5 to 10 grains; *Pulvis R. Compositus*, commonly called *Gregory's Powder*, 30 to 60 grains for adults, 5 to 10 grains for children; *Syrupus R.*, 1 to 4 drachms; *Tinctura R.*, as a stomachic, 1 to 2 drachms; as a purgative, $\frac{1}{2}$ to 1 ounce; *Vinum R.*, 1 to 2 drachms.

Rhumb-Line, in navigation, is a line which cuts the meridians all at the same angle, *i.e.*, which is always directed to the same point of the compass. It is therefore a Loxodromic Line (q. v.).

Rhyl, a watering-place of N. Wales, in Flintshire, 16 miles E. of Conway by rail, has a large and handsome church designed in First Pointed style by the late Sir Gilbert Scott (1861), a Romanesque Catholic church (1864), a townhall (1876) comprising board-offices, meat, fish, and vegetable markets, an aquarium and winter garden (1877), and a promenade pier, 2000 feet long, constructed in 1867 at a cost of £17,000. There are three English and one Welsh weekly newspapers, and steamers ply daily between R. and Liverpool. Pop. (1871) 4229.

Rhyme (properly *rime*, the *hy* being due to the false analogy of *rhythm*; Old Eng. *rim*, 'number'), the consonance of words or syllables of words, although foreshadowed in Leonine Verses (q. v.), was first elaborated in the Western world towards the close of the 4th c. A.D., when accent had gradually superseded quantity in Latin poetry. Its condemnation by Cheke, Sidney, Jonson, and Milton, as Gothic and barbarous, is confuted by the fact that the earliest rhymed Teutonic poem, the Frankish *Evangelij* of Otfried, belongs to the latter half of the 9th c. From Latin hymns R. spread to the Romance literature, attaining its full development among the Troubadours of Provence; and English is poor in rhymes compared with Italian, French, or Spanish, the last named possessing twenty-five where English has only three. Still R. is now a part of the metrical system of our language, having almost entirely superseded the older Alliteration (q. v.), and serves an important function in marking a verse or turn of the metre. To be perfect, a R. must begin on an accented syllable, the vowel-sound of which with the succeeding parts must be identical, while the preceding parts are different. According as the accent falls upon a last or single syllable, a penultimate, or an antepenultimate, the R. is termed single, double, or triple, examples being *care* and *fair*, *clothing* and *loathing*, *family* and *clammy*. Except in burlesque poetry the accent rarely falls further back than on the third syllable; but Hood's *Bridge of Sighs* is one of numberless proofs that Dryden was wrong in declaring only single rhymes to be suitable for a serious theme. See Guest's *History of English Rhythms* (2 vols. Lond. 1838), and Tom Hood's *Rules of R.* (Lond. 1869).

Rhymer, Thomas the. See RYMOUR.

Rhynchonell'a, a genus of *Brachiopod* shells, familiar both as a living and as an extinct group, the type of the family *Rhynchonellidae*. In this family the shell is usually unattached, but in some cases was fixed by a muscular stalk or *peduncle*. This stalk issued from an aperture existing under the beak of the lower or ventral valve of the shell. The arms are coiled spirally and supported by a small set of shelly loops. There are two living species of R., *R. sulcata* is the most familiar. The genus itself is first found in a fossil state in the Lower Silurian rocks, and has persisted to the present day. In Palæozoic and Mesozoic rocks, R. shells are abundant. *R. capax* of the Lower Silurian is a well-known fossil form. *Pentamerus* is the only other genus of importance included in this family.

Rhythm (Gr. *rhythmos*, 'a regular motion') is the agreement of sound with measured time in poetry and music, and the agreement of motion with measured time in dancing. It appears to be a necessity of man's nature that efforts of the same kind, in order to be sustained, must be regulated by a law of recurring

proportions. That part of a verse which receives the stress of R. is called the *arsis* (elevation); the rest forms the *thesis* (depression). See *Théorie Nouvelle de la Métrique Arabe, Précédée de Considérations sur le Rhythme du Naturel Langage*, by S. Guyard (Par. 1877).

Rhythm (*rhythmos*, 'measure') musical, the proper arrangement and accentuation of the various notes forming a musical composition. Music is rhythmical when the accents recur periodically. A rhythmical period is divided into sections, phrases, and bars, the barring being so arranged as to bring the notes with the strongest accents at the beginning of the bar. The time is duple, triple, or quadruple, according to the number of beats in a bar. In dance music and in marches the rhythmical divisions are strongly marked.

Riazan', a government of Central Russia lying along the Oka, having Wladimir on the N., Tambow on the S. and E., and Tula and Moscow on the W. Area, 16,250 sq. miles; pop. (1870) 1,477,433. It is watered by the Oka, with its tributaries the Pra, Osetr, and Pronja, and by the Don in the S.W. The surface is level and the soil fertile, 56 per cent. being under cultivation, while 22 per cent. is under wood. Rye, wheat, oats, flax, fruit, and vegetables are cultivated; and cotton, soap, tallow, and leather are produced annually to the value of 4,000,000 roubles by upwards of 6000 persons in 220 factories.—**R.**, the capital of the government since 1778, is situated on the Trubesch, a small tributary of the Oka, 115 miles S.W. of Moscow by rail. It is a well-built town, has 26 churches, 2 monasteries, and 40 factories producing linen, cotton, and ironwares. Pop. (1870) 19,990.

Rib, a moulding or projecting band on a ceiling, universal in the Gothic style. Ribs were very common in mediæval architecture both on vaulted and flat ceilings. In the earliest Norman style they are generally mere flat bands crossing the vault at right angles, the groins being plain. Later, they became moulded, sometimes adorned with zigzags and other ornaments, and with carved bosses at the intersections. Early English and all subsequent vaultings have the groins covered with ribs, and bosses or other decorations on the intersections. In the reigns of Queen Elizabeth and James I., ribs were much used on plaster ceilings, often very intricately arranged, and with intersections either plain, or decorated with small pendants.

Ribbon (Fr. *ruban*, Dutch *rijsband*, 'a band or tie'), a narrow fabric of silk, cotton, or other material, principally used as a trimming for ladies' attire. Riband (the former spelling) originally signified a band or border of a garment, and not till the 16th c. was it used in its present sense in England. Then ribbons began to be worn as showy appendages to dress, and during the reign of Charles II. they became quite the rage with gentlemen, who attached them to almost every article of attire. French ribbons were then most esteemed, and in England the manufacture was chiefly confined to London, but after the revocation of the Edict of Nantes in 1685, French Protestant refugees carried it, among other places, to Coventry, which town and St. Etienne in France are now the principal seats of the manufacture. During last century Switzerland and Germany also extensively manufactured figured ribbons, and from these countries have been adopted many of the mechanical improvements of the R. loom, whereby the most complicated designs may be produced. Among the many varieties of plain and figured silk ribbons are love, lutestring, sarsenet, satin, gauze, chine, ferret, galloon, velvet, taffety, &c. The enormous consumption of these fabrics in the United Kingdom may be judged of from the fact that during 1876 the value of the imports of silk and satin ribbons amounted to £1,718,051, and of other kinds, £75,035. The articles came chiefly from France, comparatively small quantities having been drawn from Belgium, Holland, and other countries. In the same year silk ribbons of British manufacture, valued at £201,654 were exported to British colonies.

Broad silk ribbons constitute distinguishing marks of the various orders of knighthood; that of the Garter is of a deep blue colour, and is worn over the left shoulder; that of St. Andrew a green, worn like the Garter, but never with it; and that of the Bath is scarlet, and is worn by the Knights' Grand Crosses over the right shoulder.

Ribbon-Fish, the name given to several species of *Teleostean* fishes, notable for the extreme length, narrowness, and thin-

ness of their bodies. The *Gymnetrus Banksii* (or *Regalecus Banksii*) is one of the most familiar species. These fishes are highly interesting from their appearance when swimming, having tended in some instances to give rise to tales of 'sea-serpents.'

Ribb'onism, the name assumed by a system of secret associations which existed in Ireland in greatest activity during the twenty years before 1848, the main end of which was to protect the 'rights' of Irishmen in agrarian questions. During this period the Ribbon lodges overspread Ireland like a network from Belfast to Bantry, while the headquarters of the confederation was Tipperary County, though King's County and Queen's County, Meath, Westmeath, and Monaghan—"the Gap of the North," were in turn the temporary centres of its operations. Between the lodges there was the connection of common aims and like modes of operation, but it required an extraordinary crisis and leaders of commanding character to ensure simultaneous action. R. was a league against the Saxon and the Orangeman; but in a greater sense an organisation to protect the artisan and peasant; to intimidate grasping employers, oppressive landlords, and their agents; to evade the excise, and to punish delinquents either within or without the society. Small offences were dealt with by individual lodges, but crimes esteemed capital were subjected to wider investigation, and the instruments of the assassinations were invariably despatched from a distance. The organisations prior to R. were those of the Whiteboys, who appeared about 1760; the Threshers, who are first heard of in 1806, and who regulated tithes and priests' dues, and the prices of articles required by the poor; and about 1814, the Carders, Shanavests, and Caravats, local organisations in the S. and W. R. first began about 1808 or 1810, but it did not assume importance until 1820. Though its origin was due to the existence and example of the Orange lodges, it never regarded the extermination of Protestants as an end. Its main object was to prevent any landlord under any circumstances whatever from depriving a tenant of his land, and, secondly, to prevent any tenant from taking land from which another tenant had been evicted. That R. had any connection with the Catholic Church was a delusion which many persons in England entertained, but which was dissipated by the evidence given before a Committee of the House of Lords in 1839. R. was declared illegal by the Westmeath Act, June 16, 1871. In the mean of crime for 1836, 1837, and 1838, as compared with the mean for 1826, 1827, and 1828, there appears a decrease in cases of murder and manslaughter of 10 per cent., shooting at and stabbing, 46 per cent., and conspiracy to murder, 20 per cent. A less sectarian system of government, and greater efficiency and certainty of punishments in the courts of law, have had great influence in checking R., while experience and time have shown the highly imaginative people of Ireland how many of their wrongs and the supposed remedies for these were alike unreal, imaginary, and sentimental. See Trench's *Realities of Irish Life* (Lond. 1868).

Ribeauvillé (Ger. *Kappolsweiler*), a town of the German Empire, in the province of Elsass, has manufactures of leather, paper, spirits, dyestuffs, and dress articles. An excellent white wine is largely produced. R. contains the ruins of Notre-Dame-de-Tusenbach, and of the castles of St. Ulric and Rappolstein, the latter having a high tower. Pop. (1875) 5780.

Ribera. See SPAGNOLETTO.

Rib-Wort. See PLANTAGINACEÆ.

Ribs, the name given to the long slender bones springing from the vertebrae of vertebrates, and for the most part attached in front to the breastbone, thus forming, along with the latter bone and spine, the *thorax* or *chest*. The R. may arise from various parts of the spine. In man and mammals at large they correspond in number with the dorsal vertebrae. Man has twelve pairs of ribs. The gorilla has thirteen pairs; but thirteen pairs are occasionally found in man also. Sometimes only eleven pairs occur in man. The first seven pairs of R. are directly joined by their (*costal*) cartilages to the breastbone in front. These are the *true R.* Of the remaining five pairs, the eighth, ninth, and tenth pairs are connected to the sternum mediately through their attachment to the costal cartilages of the lower true R. The eleventh and twelfth pairs spring from the spine, but are not attached to the breastbone, and are hence named *floating* or *free R.* The five last pairs are collectively named *false R.* Each rib is attached by a *head*, which is divided into two facets

or surfaces, which articulate with the bodies of two contiguous vertebrae. The *neck* of the rib is the succeeding flattened part of the bone, the *shaft* being thin and flat, and exhibiting a *bend* at the angle of the rib. The *upper border* of the rib is thick and rounded, the *inferior border* thin and sharp. The *first rib* is the shortest, and exhibits the sharpest curve. The *second rib* is larger than the first, but closely resembles it in its curvature. The *tenth, eleventh, and twelfth R.* have each only a single facet at the head, and the twelfth is much shorter than its predecessor. Each rib (save the eleventh and twelfth) is developed by three centres of ossification, the two last having only two such centres.

In some vertebrate animals (e.g., Frogs and Toads) R. are entirely wanting; and a like condition characterises the Lampreys, Hagfishes, and Lancelet as the lowest of the fishes. No division into 'true' and 'false' R. can be made in Serpents, Tortoises, Turtles, and Fishes, these animals having no breastbone. Birds and Seals have more true R. (relatively to the number of false R.) than Man; but the case is reversed in the Whalebone Whales, in which only a single pair of 'true' R. may occur. In some animals (e.g., Manatee) the R. become enormously thick and strong. The R. of lower animals may be given off from regions of the spine other than the dorsal region. Thus in crocodiles *cervical R.*, or neck R., occur. Birds have *sacral R.* (i.e., R. given off from the sacrum), and in the Amphibian *Menobranchius*, R. are found to be developed even from the tail vertebrae. Some animals (e.g., Pythons) have enormous numbers of R.—as many as 320 pairs. In *Amphiuma*, an Amphibian, there are only five or six pairs of R. The two-toed sloth has twenty-four pairs, and only nine pairs occur in *Hyperodon*, a whale. In the Flying Dragon (q. v.) certain of the anterior R. are developed to support the flying-membrane, and the Cobra-snake of India expands its 'hood' by the erection of cervical R. Serpents may be said to move on the extremities of the R., which are attached to the broad ventral shields or plates of the under surface of the body. In Tortoises, the R. are broadened and united, and form the basis of the *carapace*. The *costal cartilages* are replaced in Birds by the so-called *sternal R.*

Fracture of the R. is a very common accident, and occurs either as the result of direct violence, or of indirect force from compression of the thorax by a crush, when a good many ribs may give way at or near their angles and sometimes on both sides of the chest. Cases are also on record in which a rib has been fractured by muscular action in coughing. F. of the R. may be (1) uncomplicated, or (2) complicated with injury to the neighbouring soft parts.

The *treatment* consists in avoiding the movements of respiration as much as is compatible with the patient's comfort, and all active exertion should be forbidden. A bandage should be applied round the whole thorax, as low as the end of the sternum, when the patient has emptied the chest as much as possible by expiration, and the bandage should be supported over the shoulders to prevent it from slipping down. Sometimes a belt, fixed with buckles, is applied round the injured part, but the bandage or belt should be worn for at least a month. When the lung is injured, the complication is marked by emphysema, and this condition is manifested by a dry crackling sensation, perceptible on the very slightest touch, and so peculiar that, when once recognised, it can never afterwards be mistaken. A fracture of this kind is much more serious than a simple fracture, and the treatment varies according to circumstances.

Ricardo, David, the son of a Jewish stockbroker, whose family had come over from Holland long before, was born in London, 19th April 1772. Educated partly in England, partly in Holland, he entered on the business of the London Stock Exchange at the age of fourteen, and, having offended his father by renouncing the Hebrew faith and marrying on the attainment of his majority, he was forced to rely entirely on his own efforts. Combining to an extraordinary degree the best qualities of a merchant with those of a man of society, he contrived within a few years to retire with a large fortune, and devoted himself to scientific pursuits. He made considerable progress in mathematics, geology, and chemistry; but in 1799 the *Wealth of Nations* fell into his hands and turned him into the ranks of the economists. In 1809 he contributed a famous set of articles on the market price of bullion to the *Morning Chronicle*. These articles were afterwards expanded into the tract entitled *The High Price of Bullion a Proof of the*

Depreciation of Bank Notes. They seem to have largely influenced the Parliamentary Bullion Committee then sitting; and Mr. Bosanquet having written a pamphlet called *Practical Observations on the Bullion Report*, Ricardo answered that gentleman's strictures in *A Reply to Mr. Bosanquet's Practical Observations* (1811). In 1815 appeared his *Essay on the Influence of a Low Price of Corn on the Profits of Stock*; in 1816, *Proposals for an Economical and Secure Currency, with Observations on the Profits of the Bank of England*; and in 1817, his great work, *Principles of Political Economy and Taxation*. The last of his publications was a pamphlet on *Protection to Agriculture* (1822). He entered Parliament in 1819 as member for Portarlington, and in the House acquired great influence as a clear, though cautious and somewhat reserved debater. His death took place at Gatcomb Park, Gloucestershire, 11th September 1823. The most inoffensive and benevolent of men, R., on account of his economical doctrines, was involved in the fiercest struggles, the result, in some degree, of the ambiguity with which he expressed his views in print. The two distinctive tenets of R., those of Value and Rent, are explained, the former in POLITICAL ECONOMY, the latter in RENT. His works have been edited, with Memoir, by his enthusiastic admirer M'Culloch (1 vol. 1846). See chap. xxviii. of Picciotto's *Anglo-Jewish History* (Lond. 1875).

Ricasoli, Bettino, Baron, an Italian statesman, was born at Florence, 9th March 1809, studied at Pisa and Florence, where he became imbued with a love of Italian independence and unity. Having married early, he devoted his life to farming until 1847, when a *Memoir*, dedicated to the Grand Duke Leopold II., whose attention he drew to many administrative abuses, involved him in politics. In the events of 1848 he had no active share, though he afterwards supported the Grand Duke until he abdicated. After the battle of Novara and the treacherous reinstatement of the Grand Duke by the Austrians, R. went back to his farm, whose wine products in 1855 procured him a medal and the cross of the Legion of Honour. In 1859, on his return to political life, he became the Dictator of Tuscany, in 1861 Prime Minister of Italy, and again in 1866. R. retired in April 1867 with the reputation of being a guileless advocate of liberty, but with a conscience too keen and scrupulous for sustained success in practical politics. See Luigi Passerini's *Genealogia e Storia della Famiglia R.* (Flor. 1861).

Ricci, Matteo, founder of the Jesuit Chinese missions, was born at Macerata, in the Marches of Ancona, 6th October 1552. In 1571 he left off studying law at Rome and became Jesuit, accompanying Valignan, the 'visitor-general' of Oriental missions, to India in 1577, where he finished his theological studies at Goa, and was fixed upon as the man best suited by ability and ardour to introduce Christianity into China. He learned Chinese at Macao, but it was not till 1583 that he was allowed to settle at Tchao-King-Fu. He at once saw that to gain any influence he would have to enter thoroughly into the ways and character of the people, and gain the consideration accorded to a mandarin. With this view he published a Chinese *Map of the World*, and a little *Catechism*, in which he set forth only the great moral principles of Christianity. These works at once gained him the highest esteem. In spite of many persecutions he went on teaching, giving instructions also in mathematics and chemistry, and in 1595 attempted to go to Peking in the dress of a Chinese scholar, but was stopped at Nanking and forced to retire to Nang-Tchang-Fu, where he wrote a treatise on the *Art of Memory*, and a *Dialogue on Friendship*, which so delighted the Chinese that he was allowed to visit Peking, and finally to settle at Nanking with a daily growing reputation. In 1600 he gained an audience of the Emperor, and was allowed to build a church at Peking, where he remained till his death, 11th May 1610, skilfully retaining the favour of the Emperor, the court, and the literati, teaching science, and publishing works both scientific and religious, aiming all the while at propagating Christianity. Chinese history designates him Le-Ma-tsou, sometimes Si-thai. Among his chief Chinese works are a treatise on the *True Doctrine of God*, an *Arithmetic*, a *Translation of the First Six Books of Euclid*, and a treatise on *Practical Geometry*. But his most interesting writings are his memoirs, published by Père Tregault at Angsburg in 1615 (Lyon, 1616) with the title, *De Christiana Expeditione apud Sinas suscepta ab Societate Jesu, ex M. Riccii Commentariis libri V.*, full of precious information on Chinese history and geography.

Sixty-six letters of the illustrious missionary are still in the possession of his family.

Riccio, or Rizzio, David, said to be a native of Turin, appears in Scotch history in 1561 as musician to Queen Mary. Knox describes his position thus—'The Queen used him for secretary in things that appertain to her secret affairs in France or elsewhere.' He was, says Burton, 'virtually her secretary for foreign affairs.' R. gradually became offensive to the Scotch nobles by his personal arrogance. It was said that he was too intimate with her, and that he was engaged in Popish intrigue. Darnley and the Protestant nobles, therefore, agreed by bond that 'a stranger Italian called Davie should be put to death.' On the 9th of March 1566, Darnley introduced into the Palace of Holyrood some of the nobles. Ruthven entered the Queen's chamber, where sat 'Signor Davie' with other attendants. 'It would please your Majesty,' said he, 'to let yonder man Davie come forth of your presence, for he hath been over long there.' Angry dialogue ensued, and a scuffle in which R. was dragged from behind the Queen, thrust into an anteroom, stabbed by every knife that could reach him, and his body conveyed to the porter's lodge. See Burton's *History of Scotland* (vol. iv.).

Rice (called botanically *Oryza*, being the name by which R. was known to the Greeks and Romans) is the type genus of the tribe *Oryzæ* of the *Gramineæ*. The genus is distinguished by its panicles of single-flowered spikelets, each with two small pointed glumes, and two nearly equal paleæ adhering to the grain; six stamens, and two styles. The common R. (*O. sativa*), unlike most of the long-cultivated cereals, is still found in a wild state in some parts of India, and probably also in N. Australia. The plant is well described by Theophrastus (Book iv. c. 5). It has been cultivated in the East from time immemorial, and is now extensively grown in some of the Southern States of N. America, as also in Egypt, Italy, and the S. of Spain. It is also in cultivation in Central Africa, Madagascar, and Peru. An immense number of varieties are recognised, ranging under three categories—hard, soft, and glutinous. These do not, however, differ materially so far as the composition of the grain is concerned. R. is the favourite food-grain of the people of India; but with the exception of Burmah, Bengal, and a few other districts, in which it constitutes the chief and almost only article cultivated, its use is confined to the richer classes. It grows readily on low lands which are annually flooded, or on terraced hill-slopes; heat and moisture being the two essentials for its development. There are three modes of culture:—The first and simplest consists in sowing the seed broadcast in its natural state. In unirrigated lands this method is universally followed. In the second, the seed is steeped and then forced under warm grass to germinate. The seed with the tender shoots is then thrown into the soil, which has previously been flooded to receive it. This method prevails wherever water is abundant. In the third, the crop is raised in a nursery, and when about a month old the young plants are planted out, at stated intervals, in a well-flooded field. This system of transplanting involves a great deal of trouble, and is only followed in heavy swampy ground where the plough cannot work, although by it the yield of R. is greater than by any of the other methods. The R. crop is sown in India in May or June, and reaped in December. When enclosed in the husk, R. is known as *paddy*. By careful milling this husk is removed, and the pearled grain thus cleaned is what is generally sold in the shops, or it is ground into flour. The R.-husk, or *shude*, is harsh and fibrous in texture, and contains much lignose and silica. It is largely used in adulterating many articles of cattle and human food. Mr. Church gives the constituents of cleaned R. as—Water, 14.6; fibrin, &c., 7.5; starch, &c., 76; fat, 0.5; cellulose, 0.9; mineral matter, 0.5 = 100. R. should not be boiled, but steamed, and is most usefully employed as a food when it is consumed along with substances rich in nitrogenous or flesh-forming matters. It cannot be substituted for green vegetables for any length of time without injury to the system. R.-starch is the smallest of all commercial starches. For the process of making the much-advertised patent R.-starch, see *Ferreira, Mat. Med.* (4th ed. vol. ii. p. 73). The Chinese vermicelli is composed of a folded filament made of R.-paste. In Japan, a beer called 'saki' is made from R., and the Chinese and the aboriginal tribes of India prepare several kinds of intoxicating liquor from it. Arrack (q. v.) is the spirit distilled from R. and molasses.

In the year 1877-78 the total exports of R. from British India were 18,175,231 cwt., valued at £6,877,361, showing a decrease in quantity but a large increase in value as compared with the two preceding years. Out of the total, 10,488,198 cwt., valued at £3,347,828, were sent to the United Kingdom. British Burmah contributed 11,595,396 cwt., and Bengal 5,884,363 cwt. The Burmese exports come direct to Europe, to be used not only for food, but for making starch, &c.; the produce of Bengal, besides affording the best table R. consumed in England, is also sent in large quantities to Ceylon, the Mauritius, and the Straits Settlements. Besides this, other Eastern countries export more or less considerable quantities to the United Kingdom. Thus in 1876 it received—

From Siam	313,129 Cwts.	£122,589 Value
" Japan "	94,580 "	59,204 "
" Other countries	80,459 "	44,222 "

The R. production of the United States in 1860 was 187,167,034 lbs.; in 1870, 73,644,727 lbs., of which 32,304,825 belonged to S. Carolina (35,884,640 lbs. in 1875), 22,277,380 to Georgia, and 15,854,012 to Louisiana (12,007,380 in 1873). The R. exported from the United States in 1876 had a value of \$30,918.

In 1874 Italy had 574,692 statute acres under R., the estimated crop being 26,999,915 bushels; and Austria Proper in 1875 had 1398, an estimated crop of 18,384 cwt.

In 1875 Russia imported 621,373 *poods* of R.; value, 1,687,225 silver roubles.

In 1875 Sweden imported 8,101,602 *skatpund* of R.

In 1875 Denmark imported 16,922,125 *pund* of R.

In 1876 Holland imported 77,935,000 *kglogr.* of R.; value, 23,111,000 gulden.

In 1876 Switzerland imported 156,707 *centners* of R.

In 1874 Greece imported 2,660,608 *ocques* of R.; value, 1,816,407 drachmes.

In 1876 Italy exported 53,397,000 *kglogr.* of R.; value, 18,689,000 lire

Of other species of *Oryza*, one or more belonging to Central America serve as fodder grasses. The so-called Canada R. is the produce of the allied *Zizania aquatica* of Linnaeus, a tall grass found in shallow streams and around pools and lakes from Canada to Florida. The seeds afford a good meal, which is much used by the Indians for bread.

Rice Paper, the popular name for a snowy white, smooth variety of paper, prepared from the pith of a small plant, *Aralia papyrifera*, which grows wild in the northern districts of Formosa. When first brought to England from China, R. P. received its name from the supposition that it was made from rice. The stem of the plant is cut into lengths of 9 or 12 inches, the pith pushed out, then dried and cut spirally into continuous sheets, which are pressed and afterwards formed into squares of various sizes. R. P. is much used by Chinese artists as a surface for painting animal and flower subjects; it is also dyed and formed into artificial flowers. The *Taccada* shrub, *Scavola Taccada*, yields a similar pith, which is the source of *Malay R. P.*

Rich, Edmund, born at Abingdon, in Berkshire, towards the close of the 12th c., was sent at the age of twelve to a school at Oxford, and thence with his brother Robert proceeded to the University of Paris. Summoned home by the last sickness of his saintlike mother, he hired a hall at Oxford, and lectured there for several years, being one of the chief introducers of Aristotle to the English schools, and counting Grosseteste among his pupils. When a boy at school, he had already vowed himself to celibacy, and with quaint devotion plighted troth to an image of the Blessed Virgin in an Oxford church; now one night in a dream his mother bade him study the mystic symbol of the Trinity in place of Euclid's diagrams, and Edmund accordingly took orders, becoming treasurer of Salisbury Cathedral (c. 1220). In 1227 he preached the sixth crusade, when miracles attested a holiness that seven years later caused his elevation to the see of Canterbury. As primate he strove to follow in the steps of his great foregoer, Langton, upholding the national party in opposition to Henry's foreign hirelings, lay and ecclesiastical. But though at the Council of Gloucester, in the month succeeding his consecration, he sternly rebuked the king for his murder of the Earl Marshal, Richard of Pembroke, and effected the temporary downfall of Roches and Rivaux, he found himself thwarted at every turn by these and other favourites, foremost among them the legate Otho le Blanc; and from Rome, where he sought redress in 1238, he returned with a heavy heart. Two years later he left England for France, and, worn out by extreme

asceticism, died at the priory of Soissy, near Provins, November 19, 1240. He was canonised in 1249 as St. Edmund of Pontigny, the place of his burial, whither in September 1874 four hundred English pilgrims repaired to pay their devotions at his shrine. See vol. iii. of Hook's *Lives of the Archbishops of Canterbury* (Lond. 1863).

Richard I. (*Cœur de Lion*), second Angevin king of England, born at Oxford, 13th September 1157, was the third son of Henry II. and Eleanor of Aquitaine. Receiving the chivalrous training of the period, he became noted for proficiency in arms, for musical and poetical skill, and also for a daring and turbulent spirit. Engaging with his brothers Henry and Geoffrey in a revolt against Henry II., whose ambitious schemes for his sons were only rewarded by ingratitude, R. fled to France in his sixteenth year, and was there knighted by Louis VII. On the death of his brother Henry he became heir-apparent, and refusing to give up Aquitaine to his brother John, as the king wished him to do, he became involved in a contest with John and Geoffrey, and invaded Brittany, of which Geoffrey was ruler. His father having reconciled him with his brothers, he turned his arms successfully against the Comte de Toulouse. Never a very dutiful son, R., when he heard it rumoured that Henry wished the crown to pass to Prince John, did homage to Philippe Auguste for his English lands in France, and along with that king waged war on his father. Henry defended his territories in vain. Ferté-Bernard, Mans, Amboise, Chaumont, and Tours successively fell into the hands of the enemy; and, losing all hope of success, he was humiliated to the acceptance of his son's terms. These were, that R. should marry the Princess Alice, Philippe's sister; that he should receive the homage of all the subjects of England on both sides of the Channel; that Henry should pay twenty thousand marks to Philippe; that Henry's barons should engage, in the event of their master's violating the treaty, to espouse the cause of his son; and that all English vassals who had served with R. should be pardoned. Among those who had so conspired with R., the king was amazed to discover his son John; and the unhappy father, cursing the day he begot such children, died at the Castle of Chinon, muttering, 'Shame, shame, on a conquered king.' R. crossed to England with speed, and was crowned at Westminster, 3d September 1189. But he was rather a knight-errant than a king. 'Born as he was,' says Freeman, 'on English soil, no king ever had less of English feeling; none cared less for the welfare of England; none so systematically made himself a stranger to her.' Scarcely had he ascended the throne than he resolved to raise a crusade—the third. The savings of his father were appropriated for this purpose; honours and offices were sold; and the King of Scotland obtained release from his oath of homage to England on payment of 10,000 marks. The government was left in the hands of the Chancellor, William Longchamp, who was raised to the see of Ely; and on June 29, 1190, the English and French armies, 100,000 strong, met on the plains of Verela in Burgundy. Philippe conveyed his troops to Sicily by way of Genoa, while Richard proceeded by Marseille. The Crusaders spent the autumn and winter in Sicily; and the French king siding with the King of Sicily in a quarrel with R., the expedition was almost broken up. Eventually a treaty was made, by which R. was freed from his engagement to the Princess Alice, and allowed to arrange a marriage with Berengaria, daughter of the King of Navarre. Leaving Messina on the 10th of April 1191, he encountered severe storms. Some of his ships were wrecked on the coast of Cyprus, and their crews inhospitably treated by the ruler of that island, Isaac Comnenus. R., however, conquered the island in a fortnight, cast Comnenus into prison loaded with silver fetters, and before leaving accomplished his union with Berengaria. The English army reached Acre on the 8th of June 1191. The Christians had held Acre in a state of continual siege for two years, unable to make way against the skilful defence of Saladin; but the arrival of R. inspired them with new vigour, and on July 12, the city whose blockade and defence had cost 300,000 lives threw open its gates. On August 1, Philippe sailed for France, leaving 10,000 of his men under R., who marched to Jaffa, and there defeated Saladin again. But by the time he had reached the Holy City, his army was too much curtailed by war and disease, and with the prize in sight he was forced to turn homewards. He concluded with Saladin a truce of three years, three months, three weeks, three days, and three hours, stipulated that

Acra, Joppa, and other seaports of Palestine should remain in English hands, and obtained protection for all pilgrims to Jerusalem. As he had quarrelled with Philippe, and did not dare to pass through France, R. sailed to the Adriatic, and being shipwrecked near Aquileia, he put on a pilgrim's habit, with the purpose of journeying through Germany. He fell into the hands of an enemy, Leopold, Duke of Austria. The German Emperor bought the prisoner for £60,000, and confined him in a castle in the Tyrol. At the Diet of Worms, 1193, R. did homage for his possessions to the Emperor, and promised a ransom of 100,000 marks. The released king reached England only to find John aiming at the throne. A second coronation (at Winchester, 17th April 1194) 'was held to wipe out the stain of his captivity and his foreign homage.' Soon after he left England for ever. 'For the rest of his reign,' says Freeman, 'his subjects heard of him only as one who was always asking for their money for enterprises in which they had no concern; but, both then and afterwards, it was through royal demands for money that the freedom of England grew and strengthened.' While the brilliant absentee, the 'chivalrous Rufus,' was winning worthless laurels in France, the affairs of England were patriotically carried on by Archbishop Hubert, and his successor in authority, Geoffrey Fitz-Peter the Justiciar. Finally R. died of a wound received at the siege of the castle of Chaluz, April 6, 1199, and was buried at his father's feet in Fontevraud. See *The Chronicles and Memorials of Richard I.* (1864-65), two volumes of the Rolls Series, edited by the Rev. W. Stubbs from MSS. in the libraries of Corpus Christi College and Lambeth; Green's *History of the English People* (vol. i. 1877); Freeman's *History of the Norman Conquest* (vol. v. 1876).—**R. II.**, son of the Black Prince, was born at Bordeaux, 3d April 1366, and in 1377 succeeded his grandfather, Edward IV., with the evil times painted by Langland in *Piers the Plowman* for heritage. Jealousies between Lords and Commons hindered the formation of a regular regency, and the powers of government fell virtually into the hand of R.'s uncle, John of Gaunt (q. v.). The extravagance of the court and an inglorious war with France led to the imposition of the poll-tax, falling alike on poor and rich, and this again to Wat Tyler's insurrection (1381), in whose suppression the boy-king displayed both boldness and address. Scotland was ravaged fruitlessly in 1385, and R.'s attempt in 1388 to assert his independence of control resulted in the execution of his favourites, the Earls of Suffolk and Oxford. Next year, however, he quietly assumed the reins of government, and for nine years handled them wisely and successfully, pacifying Ireland in a single campaign, and at once shielding and repressing the Lollards, but always opposed by his uncle, the Duke of Gloucester (q. v.), who stood at the head of the war or popular party. Through his marriage with Anne of Bohemia, the Wickliffite doctrines were carried to Hus and Jerome of Prague, but Anne died in 1394, and two years later R. wedded Isabella the infant daughter of Charles VI. of France. Gloucester's murder at Calais, and the execution or banishment of most of his adherents, avenged the fall of Suffolk (1397), and from vengeance R. turned to render himself absolute by appointing a permanent committee of twelve peers and six commoners, by forced loans, the outlawry of seventeen counties, and other despotic measures, which roused the enmity of the whole English people. And by the banishment of Henry Bolingbroke (1398) he gave a leader to the national discontent, for during R.'s absence in Ireland Henry landed in Yorkshire, and raising an army of 60,000 men, entered London in triumph. R. returned to find his kingdom lost, and taken prisoner at Flint and brought to the Tower, resigned his crown 29th September 1399. While Bolingbroke ascended the throne as Henry IV. (q. v.), R. was conveyed to Pontefract Castle, where in February 1400 he died either of starvation or by an assassin's hand. He left the character of one whose brilliant qualities, shared by all the Plantagenets, 'were marred,' says Green, 'by fitful inconstancy and a mean spirit of revenge.' See Wallon's *R. II.* (2 vols. Par. 1864), and vol. i. of Green's *History of the English People* (Lond. 1877).—**R. III.**, eighth son of Richard, Duke of York, was born at Fotheringay Castle, 2d October 1452. On his father's fall at Wakefield (1460) he was sent to Utrecht, but returned next year after the Yorkist victories had raised his eldest brother to the throne as Edward IV. (q. v.), and by him was created Duke of Gloucester and Admiral of England. He fought for Edward at Barnet and Tewkesbury, had perhaps a hand in the

death of both Edward, Prince of Wales, and Henry VI. (1471), but must be acquitted of his brother Clarence's murder (1478). High at this time in favour with king and people, he closed a successful campaign in Scotland with the capture of Berwick Castle (1482), and on the death of Edward IV. (9th April 1483) was left Protector of the realm for Edward V. (q. v.). His first step was to break up the Woodville or queen-dowager's party by the arrest of her brother, the Earl of Rivers, and three others (30th April); the next to lodge his nephews in the Tower, which they never left alive. Differences arising in the Council, the Lord Chamberlain Hastings, R.'s partisan till now, changed sides, and on 13th June was seized and beheaded; on the 22d Dr. Shaw in a sermon at Paul's Cross impeached the legitimacy of the late king's children, and, according to More, of Edward IV. himself; the Duke of Buckingham followed suit; and on the 26th R. was enthroned as king, Rivers and his fellow-prisoners having been executed at Pontefract the day before. The popularity which greeted R. on a royal progress was quickly clouded by rumours of the murder of the princes; in October, Buckingham, at the prompting of Morton (q. v.), headed a rising in favour of the Earl of Richmond (see HENRY VII.), and his defeat was mainly due to a great tempest. He followed Hastings to the block, and R. vainly strove by lavish bounty to the Church, pardons to his opponents, and the abolition of benevolences, to stem the growing discontent. On 7th August 1485 Richmond landed at Millford Haven, and marching through Wales, encountered the royal forces on the 22d at Bosworth Field, in Leicestershire, when R., forsaken by Stanley and Northumberland, fought his way right to his rival's presence, and, crown on head, and the shout of 'Treason' on his lips, died like a boar at bay. 'The day,' says Mr. Gairdner, 'has now gone by when it was possible to doubt the evidence at least of R.'s principal crime (the murder of his nephews). At the same time he was a good general in war, liberal to the extent of imprudence, and as a king seems really to have studied his country's welfare.' The bodily deformity which has gained him the nickname 'Crookback,' although 'perceptible,' was probably not conspicuous. See J. Gairdner's *Life and Reign of R. III.* (Lond. 1878).

Richard of Cirencester (*Ricardus Corinensis*) was born in the beginning of the 14th c. at Cirencester, Gloucester, and in 1355 entered the Benedictine monastery of St. Peter, Westminster. His name occurs in documents of that establishment for the years 1387, 1397, and 1399. His proficiency in the study of British and Old English antiquities was so great that he was honoured with the title of historiographer; and Pits says that he visited the principal libraries in England in order to collect materials for his work. His history in four books extends from 447 to 1066. He expresses an intention of continuing it, but there is no proof that he did so. R.'s chronicle gives many charters in favour of Westminster Abbey, and a very full account of the lives and miracles of the saints, especially of Edward the Confessor. He likewise wrote *Tractatus super Symbolum Majus et Minus*, and *Liber de Officiis Ecclesiasticis*. These are in the Peterborough Library, and other writings of his are supposed to exist in the Lambeth Library. It was on this author that Bertram of Copenhagen fathered his forgery *De Situ Britannia* in 1747. See Mayor's *Ricardi de Cirencestria Speculum Historiale de Gestis Regum Anglie*, edited for the Public Records Series (2 vols. 1863-69).

Richards, Alfred Bate, author and journalist, son of the late J. Richards, was born in 1820. He is barrister-at-law, but for the last thirty years has been identified with literature. He is author of the following dramas:—*Cræsus* (1845), *Runnymede* (1846), *Cromwell* (1847, produced at the Queen's Theatre 1873), *Isolda* (1848), and *Vandyke* (1850), and he also wrote the dramatic version of *Norma* in which Miss Wallis appeared in 1875. His poetical works include *The Drama of the Soul* (1848), *Religio Anima* (1866), and *Medea* (1869), and he has published four volumes of *Poems, Essays, and Opinions*, and a novel *So Very Human* (1873). Mr. R. was for two years editor of the *British Army Despatch*, was the first editor of the *Daily Telegraph*, and succeeded Mr. Grant as editor of the *Morning Advertiser* in 1870. He was one of the most prominent and active promoters of the volunteer movement. He convened the meeting at St. Martin's Hall on April 16, 1859, for the purpose of organising volunteer corps, and was colonel of the 3d City of London (Artisan) regiment from its formation till 1869.

Rich'ards, Brin'ley, an English composer, was born in Carmarthen in 1819. He obtained the King's-Scholarship at the Royal Academy of Music in 1835, and again in 1837, and subsequently became a professor in that institution. R. has written a large number of concertos, tarantelles, studies, &c., for the piano-forte, and some hundreds of songs, including 'God Bless the Prince of Wales,' which has become a sort of supplementary national anthem. He is also celebrated as a pianist.

Richardson, Benjamin Ward, M.D., F.R.C.S., a distinguished physician and scientist, was born at Somerly, Leicestershire, October 31, 1828, and graduated at St. Andrews in 1854. He undertook the editorship of the *Journal of Health* in 1855, and in the following year gained the Astley-Cooper prize for a treatise on the coagulation of the blood, and the Fothergillian gold medal for an essay on diseases of the foetus. He is the originator of several novel and original medical processes, such as the use of ether spray for local pain, and methyline bichloride as a general anæsthetic, and is one of the ablest and most successful experimenters in his profession. He has been a careful student of the effects of modern tastes and fashions upon health, and he is an earnest sanitary reformer. In 1868 he was presented with a testimonial and a thousand guineas by 600 professional friends in recognition of his services to medicine and science. His writings include *Clinical Essays* (1862, &c.), *For and Against Tobacco* (1865), *Alcohol, its Action and Use* (6 lectures, 1869), *Diseases of Modern Life* (1876; 4th ed. 1877), and *Hygeia, a City of Health* (1876). The last-named work made a great impression on the public mind.

Richardson, Charles, LL.D., born in July 1775, abandoned the study of law for that of linguistics, and in 1815 produced his *Illustrations of English Philology*. Intrusted with the lexicographical portion of the *Encyclopædia Metropolitana* (1818), he afterwards published the results of his labours separately as a *New Dictionary of the English Language* (2 vols. 1835-37; new ed. 1863). R. was also author of a treatise *On the Study of Language; an Exposition of Tooke's Diversions of Purley* (1854), and a frequent contributor to the *Gentleman's* and other magazines. He died at Feltham, in Middlesex, October 6, 1865.

Richardson, Samuel, was born in Derbyshire, 1689. Intended for the church by his father, a joiner, he never received more than the simplest village schooling, and in 1706 was bound apprentice at London to John Wilde, a printer in Stationer's Court. Many were the female hearts in Derbyshire the chubby young 'prentice left inconsolable. He writes: 'As a bashful and not forward boy, I was an early favourite with all the young women of taste and reading in the neighbourhood.' For some of these girls he was in the habit of writing love letters, and not a little of the knowledge of woman displayed in *Pamela* went up to London with the youth of sixteen. His London master soon called him 'the pillar of the house;' at the end of seven years he became a trusted foreman, and then he set up business for himself in Salisbury Court, Fleet Street, marrying the old printer's daughter. In Salisbury Court he worked not only with types but with pen, being employed occasionally to furnish indices, prefaces, and—as he calls them—'honest dedications,' for books of the day. He obtained the printing of the House of Commons journals, in twenty-six folio volumes; in 1754 was elected Master of the Stationers' Company, and six years later bought a half interest in the patent of king's printer. As a business man he had proved very successful and very popular. But when more than fifty years of his life had passed, two booksellers chanced to ask R. to write a collection of familiar letters, and in so doing prepared the way for the first English novel. R. was by nature more of a woman than a man, and like all clever women he showed to advantage in the epistolary form of composition. Considering this project of the humble guide to letter-writing, he formed the resolution of combining the epistles into a story, so that he 'might possibly introduce a new species of writing that might turn young people into a course of reading different from the pomp and parade of romance-writing; and, diminishing the improbable and marvellous with which novels generally abound, might tend to promote the cause of religion and virtue.' The story was accordingly written in three months, and appearing in 1741, took Europe by storm. Five editions were published within the year. *Pamela, or Virtue Rewarded*, a tale we should hardly

nowadays include in a course of reading for young people, details the designs of a young rake on his beautiful servant, who combines singular devotion to the person of her master with firm resistance to his wiles. She at length gains virtue's reward by driving to church with this utter scoundrel, who can gain her no other way than by the parson's help; and so she marries him, amid the pious hosannas of all her friends. The novel, which at best inculcates but a prudential morality, was publicly praised from many pulpits, though Dr. Watts was no doubt right in telling the author that ladies could not read it without blushing. The young town wits, moreover, were not slow to make merry over its priggishness; and Fielding wrote his first novel, *Joseph Andrews*, to burlesque it. R. added a sequel to *Pamela*, but with no addition to his fame. In the year 1749 he published the first two volumes of *Clarissa Harlowe*, a book ultimately extended to eight volumes. By this, indeed, the wits were hushed into respect; for the history of *Clarissa*, tedious though it be, is yet a minutely truthful analysis of human passions, and towards the close develops an interest only the highest tragic powers could enlist. But its villain, *Lovelace*, found favour with so many of R.'s fair correspondents, that the author hastened to put before them his ideal of a true Christian gentleman. The *History of Sir Charles Grandison*, extending to seven volumes, appeared in 1753. Sir Charles has become the proverbial prig of literature; but the mental derangement of *Clementina* is in this book so skilfully unfolded, that a cautious critic has gone the length of saying that for strokes of nature and passion it surpasses the madness of *Orestes* or *Lear*. These three novels are all the works of R. worth more than mention. The world he depicts in them is a narrow world. He studied it over his tea-cup and from the gossip of a hundred female scouts. Dr. Johnson, who placed him far above Fielding, yet declares, 'Were you to read R. for the story, your impatience would be so fretted, you would go hang yourself.' Yet in deserting the elaboration of incidents for the study of character, R. had the merit of adding a new form to literature. If no single page of his rises above mediocrity of sentiment, yet the whole effect of any one book is near akin to that of genius. R.'s first wife died in 1731, leaving five boys and a girl. His second wife bore him five girls and a boy. He himself, having lived a life stained by no vice, and by nothing more criminal than vanity, died on the 4th of July 1761. His inconsiderable writings are *Negotiations of Sir Thomas Roe in his Embassy to the Ottoman Porte* (1740), an annotated edition of *Aesop's Fables, Familiar Letters*, and additions to Defoe's *Tour through Great Britain*. His correspondence, which showed his vanity more than his talent, was edited in six volumes, with *Life*, by Mrs. Barbauld in 1808. His complete works (19 vols.), with memoir by Mangin, appeared in 1811.

Richardson, Sir John, the Arctic explorer and naturalist, was born at Dumfries, Scotland, 5th November 1787. In 1801 he passed from Dumfries Grammar-school to Edinburgh University, from which he entered the navy as assistant-surgeon in 1807. Having graduated M.D. at Edinburgh (1816), he accompanied Franklin (q. v.) as surgeon and naturalist to the Arctic Expeditions of 1819-22 and 1825-27, in the latter descending with Kendall the E. branch of the Mackenzie River, and, after tracing the coast of the Arctic Sea eastwards to the Coppermine River, which he descended for 11 miles, travelled overland to join Franklin at the Great Bear Lake. An account of this journey was appended to the *Narrative* published by Franklin (Lond. 1829), and in 1829 R. issued the first part of his *Fauna Boreali-Americana* (Part II. *The Birds*, by Swainson and R., 1831; III. *The Fishes*, by R., 1836; IV. *The Insects*, 1837). R. was appointed physician to the fleet in 1838, inspector of hospitals in 1840, and in 1846 was created a knight. He commanded one of the three expeditions sent in search of Franklin in 1848, returned in November 1849, and published an account of it under the title *Arctic Searching Expedition: A Journal of a Boat-Voyage through Rupert's Land and the Arctic Sea* (2 vols. Lond. 1851). R. also wrote Part I. of *Icones Piscium* (ib. 1842), and contributed to the natural history of the voyages of Captain F. W. Beechey (ib. 1839), Sir James C. Ross (ib. 1845), Captain H. Kellett (ib. 1852), and Sir E. Belcher (1848 and 1855). He retired from the service in 1855, and died at Lancrigg, Grasmere, June 5, 1865. See his *Life* by J. Mellraith (Lond. 1868).

Richelieu, Armand Jean du Plessis, Cardinal, Duc de, third son of François du Plessis, Seigneur de Richelieu in

Touraine, was born at Paris, September 5, 1585. At first he was trained at the colleges of Navarre and Lisieux with a view to entering the army; but his brother Alphonse having resigned the bishopric of Luçon, R. got the offer of it from Henri IV., agreed to take his theological doctorate, was consecrated in the presence of Paul V. at Rome (1607), and in October of the same year, having obtained his degree, entered upon the duties of his office. Occasionally he appeared at court, and became known in Parisian pulpits. In 1614 he was appointed deputy to the States-General for the clergy of Poitou, and having gained the ear of Marie de Médicis, he became attached to the court, entered the Council of State, executed a mission to the Prince de Condé, departed on an embassy to Spain, and acted as War and Foreign Secretary (November 25-30, 1616). Retiring for a time to his diocese, owing to a court intrigue, R. was not able to recover his lost ground until 1620. Two years later he became Cardinal, but not till 1624 was he ushered into the career of office. He was then called to the King's Council, and though desirous of keeping in the background, became the virtual head of it. At once he drew up a marriage-treaty between Henrietta Maria and Charles of England. The English, Dutch, and North German provinces he played off against the Austro-Spanish power, and in 1625 he checked the Spaniards in the United Provinces. In the war of the Valteline he was compelled to operate against the Pope, securing the province to the Grisons. But events turning against him, he gave up his old allies, signed a treaty of peace with the Reformed Churches and the Spaniards, thus reversing, as it seemed, his whole previous policy. From 1626 to 1628 R. set himself to crush domestic resistance, acting apparently with Spain against the Huguenots and the German Protestants. During this period a plot, which had as its object the elevation to the throne of the king's brother and R.'s death, was discovered and crushed. His domestic policy began at the same time to develop. It included the abolition of annual dues, the purchase of hereditary places, and the reduction of privilege and exemption. His plan of government became revealed as an absolute monarchy, with a free people ruled by an all-potent statesman. In 1627, carrying on his attacks on the Huguenots, R. laid siege to their stronghold of La Rochelle, which capitulated October 30, 1628, after a desperate resistance. He allowed the Huguenots, however, to exercise their own worship, but deprived them of their fortresses, their military and political privileges, and their republican right of assembly. Between 1627 and 1635 R. triumphed over his enemies at home, and definitely asserted his influence in European politics. The Spaniards were besieging Casale on the Po. R. disliked a war, but he prevented the siege, reasserted French influence across the Alps, and had a treaty signed with England, April 1629. He then changed the scene to Languedoc, and by the reduction of Montauban quelled the Huguenots. Before the end of the year he had been named, spite of the hatred of the court party, principal Minister of State and Lieutenant-General, representing the king's person in his army at home or abroad. R. became the focus for court-plotting in 1630, the queen-mother having gained temporary influence over the mind of the king. But R. faced him at Versailles, and in one interview regained his position. The queen-mother and the court ladies were exiled by him from the court. The same year he became duke, peer, and governor of Brittany. In 1632 a rising in Languedoc gave him an opportunity of removing the hostile or suspected governors of provinces, and substituting his own friends. He took time in 1635 to found the French Academy, and from that year to his death he conducted France through the Thirty Years' War, his policy being to depress Austria, and the means he used for that end being an alliance with the German Protestants. R. had been appointed Lieutenant-General of the realm, with full powers, when he died at Paris, December 4, 1642. His character has been estimated from many points of view. Corneille satirised him in the remark that 'pride, ambition, self-interest, avarice, clothed with his name, dictated laws to France.' Montesquieu called him 'one of the two worst citizens France has produced.' Yet an examination of his *Testament Politique* reveals a nobly merciful interest in the welfare of France, and a desire to lighten the taxation of her peasantry, and to elevate her industries and commerce. His temperament was certainly cold and repellent. He had a relentless strength of purpose. He was courageous, watchful, cunning, and unscrupulous in the application of means to ends. But his greatness as a

statesman, judged by historical results, and the permanent influence he has exercised on the destiny of France, cannot now be gainsaid. See *Les Mémoires de R.*, published by Petitot (Par. 1823); Sismondi, Martin, and Michelet's *Histories of France*; Kitchin's *History of France*, vols. ii. and iii. (1877); and Marius Topin's *Louis XIII. et R., avec Lettres inédites* (Par. 1876).

Rich'mond, an interesting town of England, in the county of Surrey, and a favourite summer resort of Londoners, is beautifully situated on the summit and slope of R. Hill, which rises somewhat abruptly from the right bank of the Thames, 10 miles W.S.W. of the metropolis by rail. The famous terrace extending along the brow of the hill commands a broad, magnificent bend of the Thames, the further windings of the river between the soft green of the Twickenham shores and the leafy masses of 'unbrageous Ham,' and a wide radius of rich, varied landscape, reaching in the W. to the grey towers of 'imperial Windsor.' Originally called Scheen or Sheen, R. is a place of considerable antiquity. Henry I. here built the palace of which, under Richard II., Chaucer was clerk and surveyor of the works. Henry VII. rebuilt the palace, and called it R. from his own earldom. Edward III., Henry VII., and Elizabeth died at R., which continued to be a royal residence till the Revolution, when the palace was partly destroyed. The Old Park, formerly the park of the palace, extends along the Thames to Kew Gardens, with which it was united by George III. What is now called R. Park, lying to the S.E., is a beautiful piece of land, enclosed by a brick wall eight miles in circuit. The river is spanned between R. and Twickenham by a handsome stone bridge of five arches, and its banks are studded with delightful villas, while in the vicinity are many lordly mansions, including those of the Duke of Buccleuch and the late Earl Russell. Sir Joshua Reynolds, Gainsborough, Collins, and Thomson resided at R., and the churchyard of the parish church contains the tombs of Thomson and of Kean the actor. The church of St. Matthias, with a spire 190 feet high, was erected from designs by the late Sir G. G. Scott in 1858. The well-known 'Star and Garter' hotel, on the slope below the terrace, was built in 1738, and after being destroyed by fire (1870), was re-erected (1872-74) at a cost of £24,000. The new palatial building has a hall 80 feet long by 61 in breadth. R. is mainly dependent on the resident gentry and the crowd of summer visitors; but there are breweries, malt-houses, market-gardens, and nurseries, and an active trade in coal, &c., by rail and river. A reservoir holding 750,000 gallons was opened in 1876. Pop. (1871) 15,113.

Rich'mond, a market-town in the N. Riding of Yorkshire, on the left bank of the Swale, 15½ miles by rail S.W. of Darlington, has brass and iron foundries, tanneries, and corn and paper mills. The parish church of St. Mary, a fine building, mainly Gothic, partly Norman, was restored in 1860, and a large and highly decorated Roman Catholic chapel of St. Joseph and St. Francis Xavier was built in 1867. The endowed grammar-school, founded 1567, has (1878) 9 masters and 80 boys, and 6 scholarships. R. publishes one weekly newspaper. The castle of the Duke of R., very picturesquely situated, overlooks the river. Pop. (1871) 4443.

Rich'mond, capital of Virginia, U.S., is situated amid a cluster of picturesque hills, on the N. side of James River, at the Great Falls, the head of the tide-water, 151 miles from the mouth. It is well built, and the surrounding scenery is beautiful. Near the city are immense quantities of fine granite, and within easy reach are the vast coal and iron veins of the state. In 1874 there were in R. 57 tobacco and 36 cigar factories, producing 23,803,189 lbs. of tobacco, and 4,072,200 cigars. There are also very large flour-mills and ironworks. The manufactured products of the city in 1874 amounted to \$17,746,720, of which the tobacco factories produced \$8,327,581, the flour-mills \$2,214,683, the ironworks \$2,946,760, and a great variety of manufactories the rest. The river has been rendered much more navigable by the James River Improvement, the mean high tide at the wharves of the lower part of the city giving a depth of about 18 feet. In the year ending June 30, 1875, there entered 44 vessels of 10,775 tons, and cleared 103 of 29,144 tons; while the exports amounted to \$2,944,642, and the imports (chiefly coffee and salt) to \$433,905. R. has a chamber of commerce,

corn and flour, tobacco and stock exchanges, the State Penitentiary, the State Capitol, a handsome edifice with a fine pillared portico, State Central Lunatic Asylum, a theatre, 51 churches, several fine cemeteries, 93 public free schools, R. College for males, under Baptist control, established 1844 (with 7 professors and 128 students in 1875), R. Female Institute, several higher schools under Roman Catholic management, a medical college, 5 daily newspapers, several religious and secular weeklies, a medical, agricultural, and educational monthly, &c. Two bridges give communication with Manchester, a small town on the S. side of the river. The water supply, drawn by steam-power from the river above the falls, amounts to 350,000,000 gallons daily. R. was made a town in 1742, and in 1779 State capital. In 1781 it was taken and burned by Arnold; in 1811, seventy persons were killed by the burning of the theatre; in 1861 it was made the capital of the Confederate States, and was evacuated after a splendid defence by Lee in 1865, when a large part of it was burnt; in 1870 sixty persons were killed or mortally wounded by the floor of the Capitol court-room giving way; and in the same year the James River inundated a great portion of the city. Pop. (1874) 60,705.

Richmond, a flourishing town and an important railway centre of Indiana, U.S., situated on the E. branch of the White-water River, in a rich and well-cultivated district, 68 miles E. of Indianapolis by rail. It has 19 churches, 2 theatres, 3 daily and 5 weekly newspapers, and many benevolent institutions. Earlham College, under the control of the Society of Friends, had (1875) 14 professors and 221 students. The manufactures of R. in 1875 were valued at £545,870. They included woollens, machinery, galvanised ironwork, furniture, and cigars. Pop. (1870) 9445.

Richmond and Gordon, Charles Henry Gordon-Lennox, Sixth Duke of K.G., eldest son of the fifth Duke, was born February 27, 1818, and educated at Westminster School and Christ Church College, Oxford. He entered the army on leaving the university, and attained the rank of captain, serving as aide-de-camp to two successive commanders-in-chief, the Duke of Wellington 1842-52, and Viscount Hardinge 1852-54. He sat in the House of Commons as (Conservative) member for West Sussex from 1841 till his succession to the title in October 1860. He was President of the Poor Law Board under Lord Derby's administration in 1859, President of the Board of Trade 1867-68, and has been Lord President of the Council since February 1874. He succeeded the late Earl of Derby in the leadership of the Conservative party of the House of Lords, a position he held till Mr. Disraeli's elevation to the Peerage, and in which his courteous bearing, tact, and business-like qualities won golden opinions for him alike from his political supporters and opponents. He was made Earl of Kinsara and Duke of Gordon in 1876. See GORDON.

Richmond, Legh, was born at Liverpool, 29th January 1772, studied at Trinity College, Cambridge, and in 1805 obtained the rectory of Turvey, Bedfordshire, where he died, 8th May 1827. He wrote several religious works, once widely read and much admired. The chief are *The Fathers of the Church*, and a volume of tales entitled *Annals of the Poor* (new ed. with Memoir, 1877). Some of these—e.g., *The Dairyman's Daughter* and *The Young Cottager*—are not yet quite forgotten.

Richter, Johann Paul Friedrich—'Jean Paul,' as he taught his readers to call him—was born at Wunsiedel, near Baireuth, in Bavaria, March 21, 1763. His father was an organist and schoolmaster at Wunsiedel, but in 1765 was appointed minister of a church in Joditz, and subsequently removed to the larger parish of Schwarzenbach, on the Saale. His father, 'poor and pious in a high degree,' allowed his son but a small amount of schooling, and at home fed his intellect with pages of the Latin Grammar or the Bible, to be committed to memory. Jean Paul entered the gymnasium at Hof, and there in a celebrated school debate completely routed the orthodox rector with sceptical weapons; but the death of his father plunged the family into debt and misery, amid which only the bravest of young hearts could have continued steady at work and presented cheerfulness. R. did work, digging deep into fathomless German philosophy, delivering orations on 'The Value of the Early Study of Philosophy,' and 'The Importance of the Discovery of New Truths'; reading hard also in every department of literature, and before

leaving school filling ten thick quarto volumes with carefully arranged notes and extracts. As for the poverty, he writes himself:—'The poor historical professor would not, for much money, have had much money in his youth. Fate does with poets as we do with birds—it darkens the warbler's cage until it has caught the oft-played air he is to sing.' In 1781 he matriculated at Leipzig University, with the view of entering the Church. This view was soon abandoned. At Leipzig he lived in the simplest manner, providing himself with a *testimonium paupertatis*, and obtaining free class tickets. In order to economise, he dispensed with collars and cravats, and affronted society by wearing no pigtail. Five years he thus spent, struggling not only for education, but for very life, meanwhile hatching the strangest literary projects. The first work sent to a publisher, *Das Lob der Dummheit*, inspired by the *Encomium* of Erasmus, was rejected; but at the age of nineteen he found a publisher for the *Grönländische Prozesse* (Berl. 1783-85). This satire found a publisher but no public, and its author, surrounded with 'unpaid debts and unsold boots,' even threatened with the debtor's prison, fled to his mother at Hof. His poverty soon drove him thence, and at Töpen he acted for three unhappy years as tutor in the house of Herr von Oerthel. During this servitude to a spoiled boy and an arrogant father, he published his *Auswahl aus des Teufels Papieren* (Gera, 1789) a work which betrayed signs only of his satirical genius. It created no stir, and its author took up school at Schwarzenbach, where he taught for four years, and where his *Levana* was sketched. But his troubles may be said to have ended with the publication of his first novel, a pedagogical romance entitled *Die Unsichtbare Loge* (Berl. 1793). This procured him notice and friends, and encouraged the completion of the well-known *Hesperus* (4 vols. Berl. 1794). *Quintus Fixlein* (Baireuth, 1796), the first book bearing the author's name, 'Jean Paul'; *Biographische Belustigungen unter der Gehirnschale einer Riesin* (Berl. 1796), and *Blumen, Frucht, und Dornenstücke* (4 vols. Berl. 1796-97) followed. R.'s plea for notice had now been made; judgment was awaited. Goethe and Schiller were cold to him, but Herder and Wieland greeted him with admiration and curiosity. Charlotte von Kalbe invited him to Weimar, whither he removed in 1798, and there falling in with Jacobi and other philosophers, he revived his old metaphysical studies, and attacked Fichte in the brilliant *Clavis Fichtiana*. At Weimar were written two minor works, *Der Fabelsenior* (Leip. 1797) and *Das Campaner Thal* (Erfurt, 1798), a treatise on the immortality of the soul. From Weimar he often went as a visitor to the court of Hildburghausen, where he was made a councillor of legation, and where he became engaged to Caroline von Feuchtersleben. This engagement, however, was broken off, and in May 1801 he married the lovely Caroline Mayer, daughter of a privy councillor. The first years of his happy married life were spent at Meiningen and Koburg. In 1803 appeared at Berlin the last volume of *Titan*, the best of his novels, begun at Weimar in 1800, and this was followed by *Fliegende Hölle* (4 vols. Tub. 1804-5). In 1804 R. settled at Baireuth, and there spent the remainder of his life. Prince Dalberg enabled him to enjoy his remaining years in some comfort with a pension of 1000 guilders. His last works were *Des Feldpredigers Schmelzle Reise nach Flatz* (Tub. 1809), *Levana*, an ingenious treatise on education, as good for the heart as the head (Braunschweig, 1807), *Leben Fibels* (Nurnb. 1812), and *Der Komte Nikolaus Marggraf* (3 vols. Berl. 1820-23). He commenced an autobiography, which only extends to his thirteenth year, and revised and collected his works in sixty-five volumes, to which five supplementary ones were added (Berl. 1825-38; 3d ed. 34 vols. 1860-63). Almost blind, but labouring to the end, Jean Paul died November 14, 1825.

Not only in the literature of his own country, but in that of all Europe, R. must be designated *der Einzige*, 'the Only One.' In our own literature, Sterne to some extent gives a notion of his erratic, whimsical humour; Swift is scarcely more biting in satire, and certainly not more carefully just; only Lamb draws tears of such refined delight, chased by such tender smiles. Jean Paul is a wit, a humourist, a satirist, a moralist; he is sportively learned, and grotesquely scientific. He envelops his reader in a whirl of the mental elements; he presents scarcely so much complete pictures as kaleidoscopic flashes of colour; he treats the solemnest themes with laughter and finds the profoundest significance in trifles. At times he is absolutely incomprehensible; at times his rioting fancy barely

escapes the charge of buffoonery, yet beneath these masks every page of his betrays a man of the deepest spirituality and the noblest imagination. His style attains the limits of the fantastic, and has been the principal hindrance to his popularity, for readers accustomed to the classic work of Lessing, or Goethe, or Schiller, are apt to turn in disgust from R.'s creaking, many-jointed sentences. He is diffuse and tautological, never knows when to have done, and overloads his style with ornament, like the Persian, hanging jewels on every leaf of his tree. No more comical criticism of Jean Paul has been given than the following title of a sober work—*K. Reinhold's Lexicon for Jean Paul's Works, or Explanation of all the foreign words and unusual modes of speech which occur in his writings, with short notices of the historical persons and facts therein alluded to, and plain German versions of the more difficult passages in the context; a necessary assistance for all who would read those works with profit.* Carlyle has written two essays on R., and translated *Quintus Fixlein* and *Schmelsle's Reise*. The last page of *Quintus Fixlein*, as it stands either in the original or in Carlyle's admirable rendering, is perhaps the most beautiful piece of descriptive prose in modern literature. The *Flegeljahre*, *Blumen-Frucht- und Dornenstücke*, *Campaner Thal*, and *Levana* have been also translated into English; the last (Bell, 1876) with memoir and autobiography of the author. One or two of the German lives of R. have appeared in English versions. See Döring's *Leben und Charakteristik J. P. R.* (2 vols. Leips. 1830); Spazier's *Jean Paul Friedrich R., ein biographischer Commentar zu dessen Werken* (5 vols. Leips. 1833); Wirth, *R. als Pädagog* (1863), and Nerrlich, *Jean Paul und seine Zeitgenossen* (Berl. 1876.)

Ricinus. See CASTOR-OIL.

Rick (Old Eng. *hrec*, 'a small heap'), in husbandry, is a piled structure of hay or corn-sheaves, having an oblong plan and a top with sloping sides, which are usually covered with thatching. During the process of heaping, a tarpaulin, called a R.-cloth, is suspended from standards over the R. to protect it from rain.

Rickets, or **Rachitis** (Gr. *rhachis*, 'the spine'), is a constitutional disease, closely allied to struma, manifesting itself chiefly in the bones, but frequently implicating other organs, more especially the great viscera. R. may commence *in utero*, but, generally, it does not begin till the child is beginning to walk, and often not till two or three years or even later. The chief causes of R. are bad feeding, bad air, and want of cleanliness; and hence R. is the most common constitutional disease among the children of the poor. The earliest symptoms of R. are, in the child, restlessness and general ill-health; the child loses all inclination to walk; dentition is retarded and the digestion is disordered. The first local indication is a swelling of the cartilaginous extremities of the long bones, most observable near the wrist or ankle, or where the ribs join with the costal cartilages. This is followed by general softening of the bones, and curvature due partly to pressure in walking or crawling, and partly to the traction of the muscles. The chest-walls are distorted, owing in part to the softness of the thoracic parietes causing them to yield to atmospheric pressure, and to the diaphragm pulling inwards the parts of the ribs to which it is attached. The common 'pigeon-breast' may also co-exist with the rickety deformity. The spine is not peculiarly liable to deformity in R., but the pelvis is often much deformed.

The treatment of R. is both medical and surgical. The diet should be wholesome and sufficient, and great attention should be paid to general hygienic measures. The child should be carefully nursed, and prevented, as far as possible, from crawling or walking. Cod-liver oil, iodide and phosphate of iron, or other ferruginous tonics, combined with general hygienic treatment, usually result in rapid improvement. The application of splints and bandages is useful only in the period of considerable softening; but indirect benefit is sometimes attained in that they prevent the child from walking.

Ric'ochet Fire, in gunnery, is a method of fire, in which the ball or shell, projected with a smaller velocity and at a greater elevation than in ordinary fire, rebounds along the ground. The elevation is necessary in order that the shot, after clearing

the parapet which covers the line of troops or works aimed at, may descend immediately upon these, dismounting the guns, or raking the troops, as the case may be. R. F. was first employed in 1572 at the siege of Haarlem, and was reduced to method and rule by Vauban in 1688.

Ricord, Philippe, son of a French *émigré*, was born at Baltimore, U.S., December 10, 1800. After studying medicine at Philadelphia, he went in 1820 to Paris, where, at the hospital of Val-de-Grâce and at the Hôtel Dieu, he worked under the guidance of Dupuytren and Lisfranc. In 1826 he obtained his degree. He practised first at Olivet, near Orleans, and afterwards at Crouy-sur-Ourcq; but in 1831 he obtained the post of chief surgeon in the Hôpital du Midi at Paris. In 1850 he was elected a member of the Imperial Academy, and in 1869 he became consulting surgeon to the Emperor. His practice is the largest in Paris. His works, chiefly dealing with venereal diseases, in the study and treatment of which he has made himself famous as a specialist, are *Mémoire sur l'Emploi du Speculum* (1833); *Sur l'Inoculation artificielle de la Vérole chez l'Homme* (1833); *Sur la Blennorrhagie de la Femme* (1834); *Monographie du Chancre* (1837); *Traité Pratique des Maladies vénériennes* (1838); *Clinique Iconographique de l'Hôpital des Vénériens* (1841-49); *De la Syphilisation et de la Contagion des Accidents secondaires* (1853); *Lettres sur la Syphilis* (1854-57). R. has also contributed largely to the medical journals of Paris.

Riddles, or roundabout definitions of objects which the hearer is left to name, ranked higher in antiquity than now. The *Eddas* and every Aryan folklore teem with them; Samson propounded them to his wedding guests, and Hiram and the Queen of Sheba to Solomon; while Oedipus, in the myth, wins wife and kingdom by his solution of the enigma of the Sphinx. Even to-day in the Russian government of Pskof a bridegroom only gains admittance to the cottage of his bride by answering any R. she may put to him; and these same R. often show traces of primeval faiths, as this: 'A black cow overthrew the world, a white cow set it up again,' where the black cow stands for night, the white for day. Except in times when men were as gods, who could have ever guessed that by 'Over water, and under water, and never touches water,' was meant a girl crossing a bridge, and bearing on her head a pail of water? But in wadways, when their answer is always known beforehand, these 'sense-R.' (so Mr. Tylor calls them) give more delight than those new-fangled punning conundrums, whose spirit is wholly foreign to the *Demands Joyous* of Wynkyn de Worde or any such like time-honoured collections. See Friedrich's *Geschichte des Räthels* (Dresd. 1866), and vol. i. of Tylor's *Primitive Culture* (Lond. 1871).

Ridge, the upper horizontal timber in a roof, upon which the upper ends of the rafters rest. Ridges are often ornamented with crests or running designs.

Rid'ing (Old Eng. *thrithing*, 'a third part'), one of the three divisions of Yorkshire, each of which was subdivided into three or more wapentakes or Hundreds (q. v.), and was under the government of a thrithing-man.

Rid'ing-Mas'ter, in the British army. In the cavalry, non-commissioned officers and soldiers are selected and trained at the dépôt at Canterbury, to be riding instructors in their corps. A R.-M. has the relative rank of lieutenant; his pay runs from 9s. to 12s. 6d. a day, besides an allowance for expenses, and after 30 years' service (15 of which must have been as R.-M.) he may retire with the honorary rank of captain and 10s. a day. The Artillery are taught riding at the riding establishment at Woolwich.

Rid'ley, Nicholas, descendant of a knightly stock, was born about 1500 at Wilmontswick, Northumberland, and from the grammar-school of Newcastle proceeded to Pembroke College, Cambridge, where he obtained a fellowship, and was ordained in 1524. He also studied theology at Paris and Louvain (1527-29), on his return becoming under-treasurer to the university, senior proctor (1533), and public orator. Foxe attributes R.'s adoption of the Reformed doctrines to the reading of Bertram's book upon the sacrament, and to conference with Cranmer and Peter Martyr. Anyhow, we find him procuring a

decree of the university against the spiritual power of the Pope, acting as Cranmer's domestic chaplain (1537), and shielded by the archbishop from a charge of heretical preaching (1541). To Cranmer's favour he owed the livings of Herne and Soham, the mastership of Pembroke College (1540), a royal chaplaincy, and a Westminster prebend (1545). In 1547 he was raised to the see of Rochester, and thence, on Bonner's deposition three years later, translated to London, where he did the nation good service by stimulating Edward to the foundation of Christ's, St. Thomas's, and other hospitals. He helped to compile the Liturgy and Articles, and in 1552 visited Mary at Hunsdon, to win her from Papistry. His repulse led him warmly to espouse the cause of Lady Jane, the 'Twelfth Day Queen,' and in a sermon preached at Paul's Cross on July 16, 1553, R. declared both Mary and Elizabeth to be illegitimate, 'whereat,' says Burnet, 'the people murmured.' On Mary's proclamation, however, he speedily repaired to her at Framlingham, but met with a cold welcome, lost all his dignities, and was sent to the Tower, 'mounted on a lame, halting horse.' There his heart failed him, and he attended mass, for which a fellow-prisoner, Master Bradford, lashed him so fiercely with his pen, that never afterwards did he pollute himself with 'that filthy dregs of antichristian service.' In March 1554 he was sent down to Oxford, with Latimer (q. v.) and Cranmer, to be tried by a Committee of Convocation, and after a disputation, as fair as those of the succeeding reign, was pronounced an obstinate heretic, a sentence which the fact that England was still unreconciled to Rome rendered irregular. So for eighteen months he lay in Bocardo Jail and at the Mayor of Oxford's house, writing a lamentation over his country's downfall, a farewell letter to his friends, and to the temporal lords a passionate appeal to rescue England from false shepherds. On October 16, 1555, after a second trial, he was led with Latimer to the stake, his marriage, as he had smilingly called it when supping with his friends the night before. That R. surpassed all other prelates of the Reformation in learning is manifested by his *Works* (ed. for the Parker Society by the Rev. H. Christmas, 1841), and in honesty by his adherence to the vow of celibacy taken at ordination. He showed his genial temper in charity to the poor, in kindness to 'my mother Bonner' and Archbishop Heath, his prisoner for a year, and in his love of tennis, archery, and chess. His harshness towards the anabaptists may fairly be imputed to the times; and if he rebelled, he paid the forfeit bravely with his life. See Foxe's *Actes and Monuments*; the histories of Froude and Lingard; R.'s *Life*, by his descendant Gloucester R. (1763); and vol. iii. of Wordsworth's *Ecclesiastical Biography* (2d ed. 1818).

Rien'zi, Nic'olo, commonly called **Cola di Rienzi**, was born in Rome about 1310. His father Lorenzi (abbreviated Rienzi) was a tavern keeper, and his mother a washerwoman. Though his origin was so humble the boy was of very distinguished appearance, and received a good education, becoming an enthusiastic student of Cicero, Seneca, Cæsar, Valerius Maximus, and, above all, of Livy. He adopted the profession of notary, and in 1342 had attained such a public position as to be included in a deputation to Clement VI. at Avignon. Here he first displayed his extraordinary eloquence in urging the restitution of the Holy See at Rome; and although his efforts were unsuccessful, Clement declared that he could wish to hear him every day. During this visit R. made a friend of Petrarch. Returning to Rome, he exerted himself in leavening the popular mind with revolutionary sentiments, enduring many indignities like Brutus, and according to his own account becoming 'by turns serious or silly, cunning, earnest, or timid, as the occasion required.' The eternal sovereignty of Rome, and her right to appoint her rulers, were the themes upon which R. descanted to the gratified mob. He chose for his text on one occasion the *Lex Regia*, engraved on copper plates which still remain in the church of St. John Lateran. Thither he invited the people; he drew from this enactment—really a proof of the Senate's servility to Vespasian—the boldest arguments for freedom, and succeeded so well as to hold large numbers in readiness for any insurrection he might command. One or two midnight meetings on the Aventine matured the conspiracy; and on the day after Ash Wednesday, 1347, R. affixed to the door of San Giorgio a scroll bearing these words: 'Ere long Rome will return to the

good estate.' The following night he spent in the church of St. Angelo, hearing thirty masses of the Holy Ghost, under whose influence he believed himself to act. At ten in the morning he issued in full armour, but with bare head. Three banners accompanied his procession, one for liberty, one for justice, one for peace. Ascending the Capitol, he caused the laws of the good estate to be read. These enacted that the citizens should be furnished with a special guard for their protection; that the right of nobles to maintain strongholds should be abolished, and that these strongholds should be handed over to the people's delegates; that no civil suit should be protracted beyond fifteen days; that in each harbour of the coast a vessel should be stationed, for the assurance of shipping; that a standing militia of 360 horse and 1300 foot should be levied and supported in the city; that one hundred pounds should be paid to the heirs of every soldier who died in the service of his country; that the revenues of the apostolic chamber should be applied to the maintenance of the public safety, the establishment of granaries, and the relief of orphans and widows.

Such were some of the salutary provisions of this constitution, which was adopted by acclamation. R. was created Tribune, and assumed the title in these words: 'By the grace of Jesus Christ, Nicholas, severe and merciful, deliverer of Rome, defender of Italy, champion of mankind and of liberty and peace and justice, Tribune august.' The revolution seemed complete; the nobles were quelled; peace and commercial prosperity prevailed everywhere; Rome, before a den of robbers, was disciplined like a camp. R. boasted, 'It was hardly to be believed that the Roman people, till now full of dissension and corrupted by every kind of vice, should be so soon reduced to a state of unanimity, to so great a love of justice, virtue, and peace; that hatred, assaults, murder, and rapine should be subdued and put an end to.' Embassies from Florence, Perugia, Venice, and Siena congratulated the Tribune on his successful administration; more than one sovereign did the same. R. now commanded Rome: had he commanded himself, he might, by-and-by, have assumed the purple with safety, and founded a dynasty. But once the promptings of patriotism had given place to the goad of ambition, all prudence was left behind. The tribune's splendour rivalled the magnificence of Cæsar; while the people unthinkingly applauded, until the approach of State bankruptcy turned their applause into curses. On August 1st, R. was knighted in the Lateran Church. After the ceremony he extended his sword to three corners of the earth, exclaiming, 'This is mine!' and he summoned Pope Clement, Karl IV., and Ludwig of Bavaria to appear before him. A fortnight after this, he was crowned in the Church of Sta. Maria Maggiore with seven crowns, which symbolised the seven gifts of the Holy Ghost. The infuriated nobles—Colonnas, Ursinis, Savellis—assembled in arms before the city. R. scattered them. But the Pope's excommunication now overtook him; public confidence did not support his policy, for he had sunk from luxury into vice; the freebooter Minorbino seized one of the palaces of the Colonnas, and declared himself master of the city. R. had no means of opposing this intruder; he had played the desperate game of double or quits too long, and abdicated after a reign of seven months. Taking refuge in the castle of St. Angelo, he escaped in a priest's dress to a Franciscan monastery in the southern Apennines, where he remained two years and a half. But the prophecies of a brother monk induced him to visit Prague and urge Karl IV. to invade Italy. The Emperor sent him as a prisoner to Avignon; whence Innocent VI. on his accession despatched him to restore the Papal authority at Rome. In the summer of 1354 he entered the imperial city as a senator; but, aiming immediately at an absolute tyranny, he was defied by the Colonnas, whose castle of Palestrina he besieged in vain. Four months after his restoration, the mob was yelling at the Capitol, 'Down with the traitor who imposed the taxes.' He addressed the people from a balcony, but was driven back by showers of stones. He was seized in the disguise of a doorkeeper, led to a platform at the foot of the Capitol stairs, and after standing mute and motionless there for an hour, was run through the body, and hacked to pieces, 8th October 1354. Twice had R.'s bravery and eloquence gained him the entire confidence of the Roman people; but the power they bestowed only intoxicated him. Still, he had great virtues; again and again in his career he gave the noblest proofs of patriotic generosity. His madness was of the head, not of the heart. An apology for him will be

found in the appendices to Bulwer-Lytton's novel of *R.* An important collection of his letters, addressed to the Emperor and the Archbishop of Prague after his fall, has been published in German by Papencordt, under the title of *Cola di R. und seine Zeit* (Hamb. 1841). See Italian lives by Fortificca and Re (1624 and 1828), Du Cerceau's *Vis de R.* (Par. 1772, translated into English, 1836).

Ries, Ferdinand, an able composer and pianist, was born at Bonn, 29th November 1784. He studied at Vienna under Beethoven from 1801 to 1804, after which he achieved a great reputation as a pianist in the many countries he visited professionally. During a long residence in England (1813-24) his services as a teacher and performer were in immense demand. He composed the operas *Die Räuberbraut* (1829) and *Liska* (first produced as *The Sorceress* at the Adelphi, London, 1831), six orchestral symphonies, several overtures, a cantata, *Der Sieg des Glaubens*, nine pianoforte concerts, and many excellent pianoforte works, violin quartets, &c. He died at Frankfurt-am-Main, 13th January 1838. See Fétis, *Biogr. univ. des Musiciens* (new ed. 1878).

Riesengebirge ('Giant Mountains,' Czech. *Arkonošs-Hori*), a range of mountains, runs from S.S.W. to N.N.W. between the sources of the Bober and the Queis, separating Bohemia and Prussian Silesia. The length is 23 miles, the breadth about 14. The highest peak is the Schnee Koppe ('Snow Top'), 5275 feet, while the general height of the range is about 4000 feet.

Rie'si, a town of Sicily, province of Caltanissetta, 16 miles N.W. of Terranova, has large chemical works, and a trade in agricultural produce. Pop. (1874) 11,548.

Rieti (the ancient *Reate*), a town of Central Italy, province of Perugia, on the Velino, 43 miles N.W. of Rome. It was one of the principal cities of the ancient Sabines, but the only traces of its antiquity are a few inscriptions preserved in the town-hall. R. has nine churches, among them a cathedral, dating from 1456, and containing a monument by Thorvaldsen. Woollen stuffs, leather, and silk are manufactured, and in the neighbourhood there is a large beetroot-sugar factory, the earliest in that part of Italy. Pop. (1874) 11,478.

Rietsch'el, Ernst, a famous German sculptor, born at Pulsnitz, 15th December 1804, studied at the Art Academy of Dresden, and later under Rauch in Berlin, was appointed in 1832 Art Professor in the former city, and died 21st February 1861. He had a marvellous power of combining idealism with fidelity to Nature. His masterpiece is the 'Luther Monument' at Worms; other notable works are a Pietà (Potsdam), a statue of Lessing (Brunswick), statues of Goethe and Schiller (Weimar), the relief decorations of the Berlin opera-house, and the Dresden museum. See Oppermann's *Ernst R.* (Leips. 1863).

Rif, The, or Riff, the name of the northern portion of Morocco, from Tangier to the Algerian frontier. It is about 220 miles long and 60 miles wide, with a mountainous surface and a rugged coast. From the last feature it derives its name. The region is well wooded and watered, and large numbers of cattle are reared on the upland pastures. The inhabitants, who are Berbers (q. v.), are of a predatory disposition, and yield little more than a nominal allegiance to the Sultan of Morocco. So late as 1844 they were notorious for piracy. Cattle, leather, bark for tanning, and orchella weed are the principal exports from the R. Spain has a foothold at four places on the coast, viz., Centa (q. v.), Melilla, Peñon de Velez, and the island of Alhucemas.

Rifled Arms, the designation given to ordnance and small-arms in which the interior of the bore is furrowed with grooves having a certain degree of spirality from breech to muzzle.

Military Rifles.—It is only within the last twenty-five years that R. A. have come into general use, although it is said that Augustin Kutter of Nurnberg invented a firearm with spiral grooves as far back as 1528. Practically, however, the year 1853 (when the Enfield rifle was adopted by the British Government) may be said to be the time when R. A. came into use for military purposes. Previous to that date (about 1826), a rifle invented by Captain Delvinge had been issued to a few men in the French army, but speedily abandoned. In 1837 the Minie

rifle was introduced, a four-grooved rifle taking a conical bullet, with a recess at the base provided with a small iron cap, which the force of the explosion drove into the bullet, causing the lead to expand into the grooves.

It is necessary to explain that previous to the introduction of R. A. the barrels of both small-arms and ordnance were made with a smooth cylindrical bore, firing as a rule a spherical ball. With such arms it was impossible to secure accurate shooting at anything but very short ranges, owing (1) to windage in consequence of the ball not fitting the bore tightly; (2) the force of the explosion 'upsetting' or changing the shape of the bullet slightly, and (3) from the ball acquiring a rotatory motion by friction against the barrel, so that when it left the muzzle the direction of its rotation would be upward, or downwards to right, or left, according to whether it touched the bottom, top, or left or right side of the barrel.

By rifling the barrel with spiral grooves, and using a conical projectile, these defects are remedied. The explosion of the powder upsets the base of the bullet, preventing windage and giving to the bullet a rotation on its own axis proportioned to the degree of spirality of the rifling, so that, the force of gravity or atmospheric pressure excepted, it keeps that axis in the line in which it leaves the muzzle of the firearm.

The soundness of the principle of R. A. with a conical bullet being demonstrated by the success of the Enfield Rifle—a three-grooved segmental cut barrel of .577 inches bore with a spiral of one in 78, i.e., the grooves take one complete turn in 78 inches (for section, see fig. 1)—inventions in this direction came thick and fast, the general tendency being to reduce the size of the bore and increase the pitch of the rifling. Among the first in the field was Mr. (now Sir Joseph) Whitworth, who was entrusted by the British Government to carry out a series of experiments to determine the best size of bore, form of rifling, and projectile for a military weapon. After protracted trials and the expenditure of large sums of money, Sir Joseph produced a hexagon barrel of .451 bore with a spirality of 1 in 20, which, with a mechanically fitting bullet, gave excellent results up to 1000 yards. (A section of Whitworth barrel is shown at fig. 2.) Before this Mr. Lancaster had, however, introduced an elliptical bore having a spiral (for section, see fig. 3), and a number of his rifles were served out to the Royal Engineers. In 1860 an entirely novel form of rifling (a section of which is shown at fig. 4) was introduced by Mr. Alexander Henry of Edinburgh. This, as well as the other systems already mentioned, was designed for muzzle-loading arms. On the conversion of the Enfield to a breechloader on the Snider system (see BREECHLOADER), the three-grooved segmental cut of rifling was still retained, and is used in that rifle at the present time.

The Snider-Enfield proved a most serviceable weapon, but in its turn it was supplanted about 1873 by an entirely new breech-loading small-bore rifle—the Martini-Henry—which has been described 'as the most magnificent weapon ever placed in the hands of a soldier.' As the breech-mechanism of the Martini-Henry is described under BREECHLOADERS, and the nature of its charge under CARTRIDGE, it is only necessary here to mention a few facts regarding the barrel. It is formed of steel drilled out of the solid; the length is 32½ inches, the calibre .45 in., and the rifling polygonal, on the patent principle of Mr. Alexander Henry. From the section of this barrel (shown at fig. 4) it will be observed that ribs in the angles create re-entering angles, and that a circle inscribed within the bore is tangential to both the plane sides and the ribs. The pitch of the rifling is one turn in 22 inches. The bullet at the base is exactly the same diameter as the minor diameter of the bore, and it takes the rifling by the 'setting-up' of the back end on the explosion of the powder.

Fig. 1. Section of 'Enfield Rifle' (actual size).

Fig. 2. Section of 'Whitworth' Barrel.

Fig. 3. Section of 'Lancaster' Rifle. Ellipsis exaggerated to show form of bore.

In range, penetration, flat trajectory, and other qualities, the Martini-Henry rifle will bear favourable comparison with any other military breechloader in existence.

Fig. 4. Section of 'Henry' Rifle.

Sporting Rifles.—The development of these has long occupied the ingenuity of inventors, and the attention given to perfecting them paved the way for the introduction of the military R. A. The favourite sporting rifle of the present day is the breech-loading 'Express,' having a slow spiral of rifling, burning a heavy charge of powder, and using a very light hollow conical bullet. The latter is propelled with great velocity; the trajectory is very low; in fact, nearly flat to about 180 yards, and the smashing power immense. For a .450 bore rifle (the favourite size for deer-stalking), the spiral of rifling is 1 in 36, charge of powder as much as 5 drachms, while the bullet only weighs 270 grains.

Match or Target Rifles differ from military R. A. in so far as the rifling has generally a slightly quicker degree of spirality; they fire a heavier charge of powder with a heavier bullet, and are provided with fine orthoptic and wind-gauge sights, and shoot with surprising accuracy up to 1200 yards. The usual bore is .450; charge of powder, 90 to 100 grains; bullet, 530 grains; weight of rifle, 10 lbs.; pitch of rifling, generally 1 in 20, or a gathering spiral commencing with almost 0 at breech, and ending with 1 in 18 at muzzle.

Rifled Ordnance became a necessity with the general adoption of R. A. As early as 1744, Benjamin Robins pointed out the advantages to be derived from rifled cannon, and prior to 1848 several experimental guns had been made; but it was only after the rifle came to be fully appreciated that the question of rifled ordnance took practical shape. Lancaster 8-inch oval bore guns were used in the Crimea by the English, but much greater success attended the second appearance of rifled guns in warfare—namely, during the Italian campaign of 1859, when the French employed converted bronze pieces with deadly effect against the Austrians.

Fig. 5. 'Polygroove' Rifling for British Breechloading Ordnance.

In that year British field-artillery were equipped with breechloading rifled guns, constructed on the coil principle invented by Sir William Armstrong, and during the following

Fig. 6. 'Woolwich Groove' for British Heavy Muzzle-loading Ordnance.

five years 3500 of different calibres (maximum 7 inches) of this type were manufactured for the British service. These breech-loading arms are rifled on the 'polygroove' system, and the elongated projectiles, slightly larger than the bore, are coated with lead, which on the explosion of the charge is forced into the grooves, causing the projectile to spin on its longer axis. Fig. 5 shows the dimensions of the 'grooves' and 'lands' of the 3-in. (9-pounder) breech-loading gun; this weapon has 38 grooves, and the twist is one turn in 38 calibres.

Heavy muzzle-loading ordnance were also constructed on Armstrong's method, and a new system of rifling, called the 'Shunt' system, was adopted for these pieces, but it has since been abandoned. In 1865, Mr. Fraser of Woolwich proposed an important modification of the Armstrong method of construction, whereby strong guns might be made at less labour and expense, and since 1867, Mr. Fraser's plan has been followed in the manufacture of heavy 'Woolwich' guns, all muzzle-loading. In Germany and France breechloading is in favour for all heavy rifled ordnance; but at Woolwich it is believed that muzzle-loaders are stronger and simpler than breechloaders, while they are not inferior in range or accuracy. Within ten years there has been an extraordinary development in the weight of Woolwich rifled guns and their projectiles, consequent on the increase in thickness of ships' armour-plating. The 12-ton gun has been rapidly succeeded by guns weighing 18, 25, 35, 38, and 81 tons. The mode of constructing these guns will be best explained by showing a section

of the 38-ton gun (fig. 7), which only differs from the 35-ton gun in having an additional length of 3 feet in the 'chase.' Setting

Fig. 7. Section of 38-ton Rifled Muzzle-loading Gun.

aside the numerous thin coils of fine iron and the forged breech-piece used in the Armstrong guns, Mr. Fraser selected wrought iron for the outer portions, and with it formed double or triple coils afterwards welded together. The 'A tube' is first roughly bored from a block of tough steel, the triple coil breech-piece is then shrunk on, the forged cascable is screwed in, next '1 B coil' is shrunk on, followed by 'B tube'; at this stage the boring and rifling are finished, after which 'C coil' with the trunnions welded in one piece is shrunk on; the piece is then vented. The 38-ton gun has a length of 230 inches, a bore 12.5 inches in diameter, and is rifled with 9 grooves of the Woolwich (modified French) pattern (fig. 6), into which studs on the projectile fit. The twist of the rifling is 1 turn in 35 calibres. The 81-ton Woolwich gun is 27 feet long, having a diameter at breech of 6 feet, and at muzzle 25 inches. The calibre is 16 inches (the powder chamber being enlarged to 18 inches), and the rifling consists of 11 Woolwich grooves increasing in twist from 0 at breech to 1 turn in 35 calibres at muzzle. With this twist the initial strain upon the gun is greatly reduced, for the projectile does not begin to rotate till it has moved forward a short distance. The charge of powder (14-inch cubes) is 425 lbs., and the elongated studded projectile, including a copper 'gas check' at base to prevent 'scoring' of the bore by the escape of gas, weighs 1700 lbs. The initial velocity is 1600 feet per second, and the striking velocity, at 120 yards, 1585 feet, the stored-up energy being calculated to carry the projectile through 30 inches of iron. The range is estimated at 15,000 yards. This monster gun has recently been beaten in weight by two 100-ton guns constructed for the Italian Government by the Elswick Ordnance Company, Newcastle-on-Tyne. Each of these muzzle-loading guns, at present (1878) the largest yet made, measures 33 feet in length, the calibre is 17½ inches with an enlarged powder chamber, the charge of powder is 470 lbs., and the projectile weighs 2280 lbs., or a little more than a ton. During experiments at Spezia with one of these guns a target composed of 23½ inches of iron and 29 inches of wood was completely runned. The rifling is on the 'polygroove' system, and the rotation of the projectile is effected by a copper cup gas check attached to the base, which expands on the explosion of the charge and enters the grooves. The efficiency of the gas check for this purpose is so great that it has been determined to apply it and the 'polygroove' rifling to the second 81-ton gun now in course of construction at Woolwich. Sir Joseph Whitworth of Manchester employs compressed steel in the manufacture of rifled ordnance, and Herr Krupp of Essen, Prussia, constructs his breechloading ordnance of cast steel, rifling on a multigroove plan, and using projectiles coated with lead.

Riflemen. All the infantry regiments in the British army are now armed with the rifle, but the Rifle Brigade (formerly the 95th regiment) and the 60th regiment (King's Royal Rifles) were so armed when the others were armed with the smooth-bore. These 'rifle regiments' have four battalions each, and they retain their dark-green uniform. Mounted R. are soldiers trained to act both as foot and cavalry soldiers, like the dragoons of former days. The last regiment of this kind in the British army was disbanded a few years ago at the Cape, but there can be no doubt of their utility in military operations, and some leading authorities, notably Sir Garnet Wolseley, have strongly advocated their revival. For rifle volunteers see VOLUNTEERS.

Ri'ga (Esth. *Rihga*, Lith. *Ria Linn*, or *Righe* 'the fortress of the Rugii'), a town of Russia, capital of the government of Livonia,

lies in a waste district on the Düna (here crossed by a floating bridge and by an iron railway bridge 2444 feet long, resting on eight pillars), 6 miles from its mouth, and 309 S.W. of St. Petersburg, with which it is connected by railway. The greater part of R. has exactly the appearance of an old German Hansa town; the three suburbs are modern, with broad, straight streets, and one-storied wooden houses. Interesting buildings are the castle, built 1494-1515 as a residence for the Grand-Master of Livonia, now a barrack, and the seat of the Governor-General of the Baltic provinces; and the 'Schwarzhaupterhaus,' belonging to a society founded in the time of the Hansa for the defence of the town. R. has also a citadel with an important arsenal, an exchange, a theatre (1863), a Greek priests' college, and numerous schools. Of sixteen churches in R. seven are Lutheran, including the Gothic Cathedral, with a museum and town library of 18,000 vols., and St. Peter's, with a spire 470 feet high, eight, including a cathedral, Orthodox Greek, and one Roman Catholic. There are also Moravian and Raskolnik chapels, and a synagogue. R. is, next to St. Petersburg, the most important of the Baltic ports of Russia. The chief harbour, named Bolderao, is at the mouth of the river, and defended by the fortress of Dünamünde. In 1876 there entered the port of R. 2755 vessels (530 British) of 794,820 tons, and cleared 2760 of 796,640 tons. The imports during 1876 were valued at £3,170,110 (39½ per cent. from Great Britain), and exports at £4,445,936 (43½ per cent. from Great Britain). The chief imports were raw cotton (£380,229), iron (£322,061), rails (£226,368), herrings, machinery, corkwood, oil, wool, salt, wine, and chemical products; and the chief exports wood (£1,296,259), oats (£796,979), flax (£561,359), rye (£467,675), hemp, barley, oil-cake, hemp-seed, and buckwheat grits. R., originally named Uxkull (*Ykeskole*), was founded in 1201 by the Livonian bishop, Albert I. of Apeldern, who established here (1202) the Livonian order of Sword Brothers, united to the Teutonic Knights in 1237. R. belonged to the Hansent League. It came under Poland in 1581, was taken by Gustaf Adolf in 1621, and unsuccessfully besieged by August II. in 1700-1. After the overthrow of Karl XII., it yielded to Russia, 4th July 1710. R. was blockaded by the English in 1854. Pop. (according to the *Petersburg Calendar* for 1877) 99,892.

Riga, Gulf of, an eastern arm of the Baltic Sea, between the Russian governments of Esthonia, Livonia, and Courland. It is about 100 miles in length from N. to S., and 70 in breadth. At the mouth of the Gulf of R. lie the islands Oesel and Dagö.

Rigadoon (Fr. *rigodon*), an old merry dance in triple time performed by a man and woman, somewhat in the style of a jig.

Rigging (from Old Eng. *wirgan*, 'to cover,' 'clothe,' or 'rig'), on shipboard, is of two kinds, standing R. and running R., the former comprising the ropes or chains used for the support of the masts, and the latter those employed in extending, taking in, and otherwise manipulating the sails. Standing R. consists of pendants, shrouds, stays, and backstays; running R. of lifts for raising the upper masts, yards, and sails, braces for trimming the yards, halyards for hoisting flags, &c., and clew-lines, sheets, tacks, and guys for the sails. A ship is said to be rigged when it is completely equipped. The men employed on board ships to fit the standing and running R. or to dismantle them are called *riggers*. R.-lofts, where rigging is fitted by stretching, splicing, &c., and made ready to be used in ships, are attached to dockyards.

Ri'ghi, a mountain mass in Switzerland lying between the lakes of Lucerne, Zug, and Lowerz. The highest point is only 5905 feet above the sea. The N. side is very steep, but the S. consists of easy slopes and broad terraces, planted with fig, chestnut, and almond trees, and pasturing upwards of 4000 head of cattle. The N. peak commands a magnificent panorama, 300 miles in circumference. Since the opening of the R. railway the number of tourists making the ascent has greatly increased, amounting in 1872 to 46,159 persons. See L. Rütimeyer's *Der Rigi, Berg, Thal und See* (Basel, 1878).

Right, Legal, is the title to the use of any subject, or to the fruits of it. But the distinction between the *corporeal* and the *incorporeal* in law has been lost in the distinction drawn between *real* and *personal*. See **REAL**. In Scotch law, see **HERITABLE AND MOVABLE**.

Rights, Declaration of, a document drawn up after the flight of James II. by a committee of the Commons, presided over by Mr. (afterwards Lord) Somers. 'It recited the misgovernment of James,' says Mr. Green, 'his abdication, and the resolve of the Lords and Commons to assert the ancient rights and liberties of English subjects. It denied the right, of any king to exercise a dispensing power, or to exact money or to maintain an army save by the consent of Parliament. It asserted for the subject a right to petition, to a free choice of representatives in Parliament, and a pure and merciful administration of justice. It declared the right of both Houses to liberty of debate.' Besides this, it confirmed the principle of trial by jury, and established that of frequent Parliaments. On the 13th of February 1689 it was presented to William and Mary in the Banqueting-room at Whitehall, and was accepted by them along with the crown. As it had been drawn up by a revolutionary committee, it was thought right to ratify it by passing it through both Houses of Parliament in due form. In its course through Parliament clauses were added providing that the King or Queen must conform to the Church of England, and must not marry a Papist. In this form it became the **BILL OF RIGHTS** in 1689. Strangely enough, it left by its silence the whole control of trade to the crown, and it was not till some years afterwards that Parliament tacitly assumed that function. The government of William and Mary in Scotland was established under a *Claim of Right* drawn up on the model of the D. of R.

Rights of Man, Declaration of the, a document drawn up mainly by Dumont, who afterwards interpreted Bentham's philosophy to Europe, and adopted as the groundwork of their constitutional labours by the French National Assembly on the 18th of August 1789, though the king did not give his adhesion to it until the 5th of October. It was in seventeen clauses, which may be thus summarised:—Men are born, and continue free and equal: The end of all political associations is the preservation of these rights—*liberty, property, security, and resistance of oppression*: The nation is the source of all sovereignty: Political liberty is the power of doing anything which does not injure another: The law should prohibit only actions hurtful to society: The law is an expression of the will of the community: No man should be molested on account of his thoughts and opinions, or for their expression and communication: Taxation should be divided equally throughout the community: Every citizen should have a voice in public affairs: The executive should be responsible to the community: The right of property is inviolable and sacred. 'With endless debating,' says Carlyle, 'we get the *R. of M.* written down and promulgated: true paper basis of all paper constitutions. Neglecting, cry the opponents, to declare the Duties of Man! Forgetting, answer we, to ascertain the *Mights* of Man;—one of the fatestale omissions!' Burke, in his *Reflections on the Revolution in France*, refers to the Declaration as 'paltry and blurred sheets of paper about the R. of M.' Thomas Paine answered Burke's invective by a pamphlet called the *R. of M.*, which led to his prosecution for libel and outlawry. It is worthy of note that the American Declaration of Independence contained the whole matter of the R. of M. in the following remarkable sentence:—'We hold these truths to be self-evident, that all men are created equal; that they are endowed by their Creator with certain unalienable rights; that among these are life, liberty, and the pursuit of happiness.'

Rig'or (Gr. *rhigō*, 'I shiver') is a term used in medicine to denote a coldness attended by a shivering more or less perfect, and is a symptom which ushers in many diseases, such as fevers and acute inflammations of internal parts. A R. is, in very many cases, a symptom indicating extreme danger.

Riliev'o (Ital.), or **Relief**, signifies the projection of a sculptured design from its ground. See **ALTO-RILIEVO**.

Rimini, a town of Italy, province of Forlì, beautifully situated on the Adriatic at the mouth of the Ansa and Marecchia, 12 miles from San Marino and 69½ S.W. of Bologna by rail. The ancient port is now choked up with sand, but the mouth of the Marecchia forms a small harbour, by means of which R. has some trade by sea, and which shelters a large number of vessels engaged in the fisheries. The town is surrounded with walls, and is well-built with regular streets and squares. The Corso, the main street, passes through the centre of the town, connect-

ing the two principal squares, Piazza Cavour and Piazza Giulio Cesare, the latter the ancient forum. The most interesting ancient structures are the five-arched Ponte d'Augusto over the Marecchia, at the point where the Via Flaminia and the Via Emilia unite, still in good preservation; the Porta Romana, a triumphal arch of white marble, erected to Augustus (B. C. 27), and the Fontana Publica, which has undergone many changes. Among more modern buildings, the finest is the cathedral church of San Francesco, one of the best existing specimens of Italian Gothic, built in the 14th c. over a temple of Castor and Pollux, and remodelled 1447-50 by Sigismondo Malatesta from designs by Leo Battista Alberti. Other buildings are the Palazzo Comunale and the church of St. Francesco, both with valuable pictures. The library, founded in 1617 by the jurist Gambalunga, has 23,000 vols. and several MSS. R. has manufactures of glass, sailcloth, earthenware, and silk fabrics. It has extensive fisheries, and wine and oil are produced in its vicinity. Pop. (1874) 9747. R., the ancient *Ariminum*, was a town of the Umbrians. It became a Roman colony in B.C. 269. Under the Eastern Empire it was one of the Pentapolis Maritima ('Five maritime cities') governed by the exarchs. Here in 350 a council against Arianism was held. R. subsequently belonged to the Lombards, and was given in 1200 by Otto IV. to the Malatestas, who, from vicereagents of the emperors, became hereditary princes. In 1503 they surrendered it to the Venetians, who were obliged to yield it to the Pope. See Tonini, *Storia Riminese* (2 vols. Rim. 1860).

Rinderpest, or Cattle Plague, is defined as a specific fever of malignant and contagious type, originally occurring in the Asiatic steppes of Russia, and only seen in Britain and in native cattle as the result of contagion derived from imported and infected cattle. R. begins with a latent or incubatory period of from four to seven or eight days. Its course is well marked. A primary fever is the first general result of the absorption into the blood of the specific poison or *virus*. The temperature rises to 103° and 104°—the normal temperature being about 101°. The first specific symptom is an eruption of the mucous membrane of the mouth, while in the cow the mucous membrane of the vagina is usually affected. About the fourth day from the first rise in temperature serious symptoms supervene, and after the fourth day the head droops, the ears hang, rigors set in, the pulse fails, and the mouth, nose, and eyes discharge a foetid secretion. About the 6th day these symptoms increase in severity, and the heart's action and breathing becomes enfeebled. The temperature falls rapidly, and death results on the seventh day from the first elevation of temperature. R. is clearly induced by a morbid poison, producing an altered state of the blood. Serum obtained from an infected animal at an early stage of the disease will infect a healthy animal; and the virus is also contained in the discharges from the nostrils, mouth, and eyes. Jessen of Dorpat maintains that these secretions retain their poisonous or infective properties for eleven months at least. The poison is said to be communicable at a distance of 500 yards. Many veterinarians consider R. to be analogous to *typhoid* or *enteric fever* in man, from its apparently analogous effects on the mucous membrane. Dr. Murchison combats this opinion, and maintains that Peyer's patches are not specifically affected in R. Cattle-plague was known in England in 1348-49. It was brought from Holland in 1745. In 1865 a noted epidemic occurred. In this latter year, during the week ending December 30th, the R. statistics were as follows:—

	Farms, &c. affected	Total cattle on affected Farms, &c.	Number of cattle slaughtered healthy
England	7,433	110,647	10,636
Scotland	2,065	44,527	6,578
Wales	1245	4536	152
Total	9,753	159,710	17,366

In 1872 another outbreak occurred, the disease having been brought to Hull, Deptford, and Leith. R. occurs in the ox, sheep, goat, deer, giraffe, camel, antelopes, &c. It is usually fatal, but where an animal recovers from one attack it is protected against a recurrence of the disease. *Inoculation* induces the disease, and appears like vaccination to render the attack of a mild nature.

Ring (Old Eng. *ring* and *hring*, Icel. *hringr* and *hringr*, from the same root as Dan. *kringle*, 'to run round'), the small hoop or circlet, usually of metal, with or without the addition of precious stones, worn on the fingers for ornament. The habit of wearing rings appears to have originated in the East at a very early period of civilised history, and among all the leading nations of antiquity the practice prevailed to a greater or less extent. The R. is frequently mentioned in Scripture, beginning in the patriarchal days of Jacob, when Tamar obtained the signet of Judah (Gen. xxxviii. 18). Again, when Joseph was advanced in the service of the Egyptian monarch, he received from the hands of Pharaoh his own R. as a token of the delegation of his powers. It thus appears that rings were primarily carried on the finger to be used as signets or seals, and their possession was a token of official place or power. At the same time we learn from Sir J. Gardner Wilkinson that rings were worn in these remote times by Egyptian women as ornaments alone, that the left hand was peculiarly privileged as the R. hand, and of that hand the third finger was more than any other the R. finger. Egyptian rings were mostly of gold, although sometimes silver was used, and among the lower orders they were fashioned of ivory and blue porcelain. Some were plain, some ornamented with scarabei and engraved stones, and in other cases the metal was worked into fantastic forms. Among the Greeks the habit of wearing rings, partly as signets and partly for ornamentation, was almost universal. The intaglios cut in onyx and other stones for ancient Greek and Roman signet-rings have never been approached for beauty, delicacy, and sharpness of outline. Among the Romans the rings first worn were made of iron alone, and it was only as luxurious habits began to prevail that at first the senators, then chief magistrates and equites were permitted to wear gold rings, the right being called the *jus annuli aurei*. Under the empire, the power of granting the privilege of the *jus annuli* was vested in the emperor alone, and by Severus and Aurelian the privilege was granted to all soldiers, while Justinian extended it to all citizens alike. The R. of the emperor was regarded as a state seal, and the use of it was sometimes given to persons to whom he might delegate any of his powers or privileges.

The giving and wearing of rings have from a very remote time been connected with the ceremonies of betrothal and marriage, and many curious customs and observances were mixed up with the practice. What the precise significance of the marriage R. originally was is not known; but as many superstitious beliefs attached themselves to the wearing of rings, and as peculiar virtues were supposed to be connected with their use, doubtless the marriage R. had originally a symbolical significance. Bishops still receive a ring on their investiture, which they wear on the third finger of the right hand as a token of power and authority. Probably the marriage R. originally indicated a similar communication or delegation of authority.

The manufacture of rings is regarded as a distinct branch of the jewellery trade, in which there are several recognised subdivisions. Thus one class of workmen fabricate ladies' ornamental rings, another is devoted to making gentlemen's heavy rings or signets, and a third makes only mourning and wedding rings. Imitation metal and paste rings, and the commoner class of gold rings, are made with dies in stamping presses much in the same way that medals, &c., are struck, the mounting of the stones in the bezel alone being hand work. All the more expensive and artistically valuable rings are, however, made entirely by handicraft, with the ordinary tools, appliances, and processes of the jeweller. See W. Jones's *Finger-Ring Lore, Historical, Legendary, Anecdotal* (Lond. 1877).

Ring-bones, the name of an affection of the horse's 'coronet.' It consists in the development of a ridge of bone around the coronet, and is regarded as due to inflammatory action causing hypertrophy. R. is commonly seen in the forefeet of draught horses. The *treatment* consists in poulticing and in keeping the whole foot cool and moist, the fetlock being afterwards blistered or 'fired.'

Ring-dove, a species of Pigeon (q. v.), known scientifically as the *Columba palumbus*, and popularly as the wood pigeon and cushat. It is a common British bird, and is known by its imperfect collar of white-tipped feathers. The head and neck are of a bluish grey, the upper parts of the body the same colour glossed with purple, and the under parts light grey. The eggs

number two, and are pure white. The nest is roughly built in trees. The average length of the R. is 17 inches.

Ring Money is the name by which antiquaries designate the rings and penannular hoops made of precious or base metal, which, there is abundant evidence to show, were used as a circulating medium by various nations in the early stages of their civilisation, and which in some countries to this day constitute the sole currency. The act of weighing money in the form of gold and silver rings is pictorially represented on ancient Egyptian monuments, and a baser medium of exchange in the shape of bronze rings has been recovered from the sites of Persepolis and Carthage, as well as in Egypt. We know, too, on the authority of Cæsar, that the Gauls and Britons used R.

African Ring Money.

M. of gold, copper, and iron; and Pliny mentions as a curious custom that they wore rings on the *middle* finger; a statement which means, according to modern archaeologists, that the smaller pieces of gold R. M. were so carried. Till the 12th c. R. M. was used in Norway, and in Africa it still continues in use, gold rings being circulated in Nubia, while among the Joliba negroes and other tribes of Western Africa, penannular hoops of copper, called 'Manillas', exported thither in considerable quantities from Birmingham, form the only recognised currency. One of these 'Manillas' is here figured to half scale, and it is worthy of note that the shape differs very slightly from that of gold R. M. found in Scottish *weems* or underground dwellings.

Ring Ouzel (*Turdus torquatus*), a species of *Insectorial* birds belonging to the thrushes, and found as summer visitants in the western and southern parts of Britain. A broad white band encircling the lower part of the throat has given the bird its popular name. The plumage is chiefly black. The R. is shy and wary. Its nest is placed on or near the ground, and the eggs, numbering five, are blue, spotted with brown.

Ring-worm is a popular term used to designate several distinct forms of skin-disease which occur in a circular or annular form on the body, and more especially on the scalp. *Herpes circinnatus*, known in popular parlance as 'the R.', occurs on the face, trunk, and extremities, and is contagious. The eruption spreads centrifugally, the original ring disappearing and giving place to a larger one, and so on. Sometimes the vesicles are large; but that form of the disease in which they are very minute, the eruption appearing to be of a furfuraceous character, is designated R. The secretion, which is contagious, seems to afford a nidus in which the parasite of *tinea tonsurans* grows. This form of R. is curable by local applications, such as sulphate of iron, gallic acid, strong acetic acid, nitrate of silver, or blistering fluid. *Tinea tonsurans* is exceedingly like *herpes circinnatus*, and both are included in the popular term R. Its seat is on the hairy scalp, and it is most common in children from two to twelve years of age. The disease is caused by the growth in the hair of a vegetable parasite—the *trichophyton tonsurans*—which imbeds itself in some unhealthy secretion of the hair follicles. The spores of the plant may be found also in the epithelium of the patch, which is heaped up in opaque white scales, occurring in round patches. The hair breaks off and falls away so completely that the part seems to have been shaved, but on minute examination the hair follicles can be detected, and after the disease is cured the hairs grow again. This form of R. is highly contagious, and in its treatment strict cleanliness must be enforced. The epithelium should be removed by a lotion of borax, and the spores of the fungus destroyed by some germicide. Sir W. Jenner recommends 5 grains of the ammonio-chloride of mercury to the drachm of sulphur ointment, or 2 grains of the perchloride to the drachm of lard, or 30 grains of nitrate of copper to 4 drachms of lard, or 10 drops of creosote to the drachm of lard, the part to be washed directly afterwards with cold water. Lotions of sulphurous acid will effectually destroy the parasites. See HERPES.

Riobamba, a town in the S. American Republic of Ecuador, 84 miles N.E. of Guayaquil, on a plain 9600 feet above the sea-level. Pop. about 16,000. The original town of R. stood at

the foot of Chimborazo, 9 miles from the site of the present town, but was destroyed by an earthquake in 1797.

Rio de Janeiro, or more strictly **Sao Sebastiao do Rio de Janeiro**, commonly shortened to **Rio**, the capital of Brazil, and the most important city of S. America. It is situated just within the tropic of Capricorn, on the western shore of the Bay of Niteroy, 4 miles from its mouth. This bay forms one of the finest harbours in the world, being easy of access, deep, and landlocked, and measuring 17 miles by 12. It is studded with eighty islands, the largest of which is 6 miles long. The entrance, which is only three-quarters of a mile wide, and is strongly fortified, is between lofty headlands, one of which, the precipitous cone of Pao d'Azuca, was ascended by four men, December 2, 1877. The old town of R. lies next the shore, and its streets are still narrow, roughly paved, and imperfectly drained, though within the last few years great improvements have been carried out. From its centre the houses extend W., N., and S. for 4 miles in each direction, communication between the city and suburbs being maintained by means of tramways. The new town lies to the W. of the old town, from which it is separated by a large open space called the Campo de Santa Anna, on which stand some of the principal public buildings of R. The houses of R. are mostly of granite, faced with white stucco, and roofed with red tiles. Trees have been planted in abundance, especially in the squares, which number fifty-three, and fountains are also numerous, the water being brought in aqueducts from reservoirs formed in the mountains by which R. is environed. Among the principal buildings are the imperial and episcopal palaces, government offices, mint, national museum, and military and naval arsenals. Churches and convents abound, and some of the former are splendid edifices. There are also many important charitable and educational institutions. In 1876 the National Library contained 120,000 vols., and forty-four newspapers and magazines were published in the city. The climate of R. is good, though, owing to the defective sanitary arrangements, yellow fever has occasionally been epidemic. The trade of R., though it has not progressed of late years, is still very extensive, the imports during 1876 amounting in value to £9,466,034, and the exports to £9,669,557. The principal articles of export were coffee, sugar, cotton, hides, tobacco, and diamonds. Pop. (1872) 274,972, of whom 48,939 were slaves. R. was founded by the Portuguese in 1567, and has been the seat of the government of Brazil since 1763.—The *province* of R. de J. has an area of 18,490 sq. miles, and at the census of 1872 its population was 1,002,548, of whom 319,665 were slaves. It is traversed by a central mountain range of granite formation, and the peaks of that part of the range called the Organ Mountains attain a height of from 6000 to 7000 feet. Offshoots from the main range form many deep and fertile valleys, in which coffee, sugar, cotton, rice, and maize are grown. The north-western portion of the province is a tableland, on which cattle are reared in large numbers. The province is well watered by the navigable river Parahyba and its affluents, and also possesses a number of lakes. Deposits of iron, lead, and kaolin exist, but, with the exception of the last, are not yet worked. The lines of railway open or under construction number twenty-seven, with an aggregate length of 890 miles.

Rio Gran'de, the name given to the great S. American river Paraná (q. v.), in its upper course, prior to its junction with the Parahyba, in 19° 40' S. lat.

Rio Gran'de del Norte. See BRAVO.

Rio Gran'de do Norte, a province in the N.E. corner of Brazil, bounded N. and E. by the Atlantic, and S. and W. by the provinces of Parahyba and Ceará respectively. Its area is 20,130 sq. miles; and its pop. at the census of 1872 was 233,979, of whom 13,020 were slaves. The interior, which is liable to severe droughts, is mountainous, but the coast is flat and sandy. Cotton and sugar are the principal crops, and cattle and horses are reared in large numbers on the upper pastures. Iron, sulphur, salt, and building-stone are abundant. In the financial year 1875-76 the imports amounted to 72,314 reis, the exports to 1,268,644 reis. The chief town is Natal (q. v.).

Rio Gran'de do Sul, or in full **São Pedro do Rio Grande do Sul**, the most southerly province of Brazil, is bounded N. by the province of Santa Catharina and the River Uruguay; W. by the same river; S. by the republic of Uruguay; and E. by

the Atlantic. Area, 110,215 sq. miles; pop. (1872) 430,878, of whom 66,876 were slaves. The province is traversed by a central mountain range, on either side of which the land declines to wide, open prairies. Close to the sea coast are the two large lakes of Dos Patos and Mirim, which are connected by a navigable channel. The former is 180 miles long, with a maximum breadth of 40 miles, and discharges into the sea by the river, only 6 miles in length, from which the province derives its name. Except in the marshy coast districts, the climate is salubrious, and several European colonies have been established. Immense herds of cattle and horses are reared on the prairies, and the principal articles of export are dried beef, hides, horns, and tallow. Maize and beans are grown largely and exported, and wheat, potatoes, and flax are also successfully cultivated. The mineral wealth of the province is very great. Gold, agates, and chalcedonies are exported to a considerable amount, and the copper mines of Santo Antonio das Lavras are the richest in Brazil, yielding 60 per cent. of pure metal. Coal, iron, and marble are abundant, and lead, silver, and sulphur are also found. In the financial year 1875-76 the imports amounted to 8,955,926 reis; the exports to 11,129,669 reis. The principal towns are Porto Alegre, at the head of Lake Dos Patos, and the port of R. G. do S., at the mouth of the river of the same name.

Riom, a town of France, department of Puy-de-Dôme, 8 miles N.N.E. of Clermont, has manufactures of silk, linen, and antimony; tanneries and distilleries; and active trade in corn, wine, cattle, hemp, flax, fruits, &c. The chief historic monuments are the Sainte-Chapelle, a fine Gothic building of the 14th c., the church of Sainte-Amable, and that of Notre Dame-du-Marthurst. Pop. (1872) 10,770.

Bio Negro ('black river'), the name of several S. American rivers, of which the two largest are the following:—1. An affluent of the Amazon, rises in the United States of Colombia, and flows successively E., S., and E.S.E., joining the Amazon at Manaos in 59° W. long. The length of its course is estimated at 1000 miles, and its channel, which is full of islands, in some parts is several miles wide. By means of the Cassiquiare (q. v.), unbroken communication is established with the Orinoco, and similar natural canals connect the lower courses of the R. N. and Japura, another large affluent of the Amazon.—2. A river forming throughout most of its length the boundary between the Argentine Republic and Patagonia. It rises in the latter country in the large lake Nahuelhuapi, at the base of the Cordillera, and flows N.E., E., and E.S.E. for fully 700 miles, till it enters the Atlantic in 41° 4' S. lat. Like all the Patagonian rivers, it is very rapid, abounds with shoals, varies greatly in volume, and has a bar near its mouth, nevertheless it is navigable for 500 miles by powerful steamers of light draught; 20 miles from its mouth is the Argentine settlement of Patagones, formerly called El Carmen.

Bione'ro in Volture, a town in the province of Potenza, Southern Italy, about 7½ miles S. of Melfi. It has considerable trade in grain, maize, and wine, and in maple snuff-boxes, which are here manufactured. Pop. (1874) 11,520.

Ri'ot. See MEETINGS, SEDITIOUS.

Ri'ot Act in the United Kingdom. By this Act, if twelve persons, or more, are assembled to the disturbance of the peace, and continue together for one hour after being commanded by lawful authority to disperse, they are guilty of felony. Silence should be commanded, and this proclamation made:—'Our Sovereign lady the Queen, chargeth and commandeth all persons, being assembled, immediately to disperse, and peaceably to depart to their habitations, or to their lawful business, upon the pains contained in the Act made in the first year of King George I., for preventing tumults and riotous assemblies. God save the Queen!' It is, of course, impossible to define a riot. The essence of rioting is probably an intention to do mischief. A noisy crowd are not necessarily rioters. Justices and constables, whose duty it is to suppress riots, therefore sometimes require to act cautiously.

Ripie'no (Ital. *full*), an occasional, or filling-up part in the orchestra, added when necessary to strengthen the principal or obligato instruments.

Ripley, George, an American author, born at Greenfield, Massachusetts, October 3, 1802, educated at Harvard and

Cambridge Divinity School, was a Unitarian pastor at Boston from 1828 to 1831, afterwards resided for several years in Europe, and became thoroughly acquainted with French and German literature. His chief works are *Discourses on the Philosophy of Religion* (1839); *Letters to Andrew Norton on the Latest Form of Infidelity* (1840); and *Specimens of Foreign Standard Literature* (14 vols. Boston 1838-42). He assisted in conducting the *Dial* (1840-41); contributed to magazines, especially the *Christian Examiner*; promoted the Brook Farm Socialist experiment (1844-46); aided in editing the *Harbinger*, a Fourierite organ (1844-48); became literary editor of the *New York Tribune* (1849); brought out along with Bayard Taylor *A Handbook of Literature and the Fine Arts* (1852); and was joint editor with C. A. Dana, of Appleton's *New American Cyclopædia* (New York, 16 vols. 1858-63). This was his great life-work. A new edition, made under his care, appeared in 1873-76. In 1874 R. received the degree of LL.D. from Lawrence University.

Rip'on, a city in the West Riding of Yorkshire, on the Ure, 28 miles N. of Leeds by rail. Its cruciform cathedral, commenced by Archbishop Roger (1154-81), continued by Archbishop Gray (1215-55), and partly rebuilt in the 16th c., presents a variety of styles, from Norman to Perpendicular. The W. front, a singularly pure specimen of Early English, is flanked by towers 110 feet high, beyond which rises St. Wilfrid's Tower, and though smaller than many cathedrals (being 266 feet long by 87, or in the transept 132 feet wide), the Minster has many interesting features—five lancets with dog-toothed mouldings, a 15th c. choir-screen with good tabernacle work, and a 7th c. crypt ('St. Wilfrid's Needle'), whose passage formed the old North Country ordeal of chastity. The whole structure was restored by the late Sir G. G. Scott (1861-71) at a cost of £40,000, and a new organ, replacing one by 'Father Schmidt,' was opened, April 24, 1878. Trinity Church (1827), with a spire of 136 feet, was also restored in 1874, other buildings being the Lombardo-Gothic Roman Catholic Church (1862), the town-hall (1831), public rooms (1834), temperance hall (1859), a free grammar school (founded in 1546), and a mistresses' training college. In the market-place is an obelisk of 90 feet, erected by John Aislabic, Chancellor of the Exchequer under George I. The manufacture of woollens, and of spurs (termed *rippons* in the slang of last century) has ceased; but iron and brassfounding, tanning, malting, and the making of varnish and saddletrees are actively carried on. R. returns one member to Parliament, and publishes two newspapers. Pop. (1871) 6143. Created a bishopric in 678, R. was subsequently united with York, and only reinstated as a separate see in 1836. Three miles to the W., in the park of Studley Royal, the Marquis of Ripon's seat, are the exquisite ruins of Fountains Abbey, established by Benedictines in 1132, with the Early English 'Chapel of the Nine Altars,' a Transition Norman nave and transept, a Perpendicular tower, and a cloister 300 feet in length. The last abbot was hanged at Tyburn for his share in the Pilgrimage of Grace (1537).

Ripple Marks, the familiar undulations left by the receding waves upon the sandy beach, are occasionally met with in rocky strata of old geologic time, and were probably due to the same agency; though in certain circumstances the wind blowing over a sandy district gives rise to a very similar appearance.

Rish'anger, William de, an English chronicler, born in 1250, became a Benedictine monk of St. Alban's, and was appointed historiographer to Henry III. He was alive in 1322. His *Chronicle*, edited by J. O. Halliwell, was printed for the Camden Society in 1840. R. also wrote the *Gesta Edwardi Primi*, some fragmentary annals, and part of the history attributed to Walsingham. All his writings are valuable for the history of Scotland at the period of its conquest by Edward I., Scotland itself not possessing at that time any chroniclers.

Rishis, or **Drish'is** ('seers,' from the root *dris*, 'to see'), the Sanskrit name for the holy men through whose agency the Vedas were revealed to mankind. None of them have individual names. They are supposed to have supernaturally seen as well as heard the divine knowledge, which they communicated by oral repetition, and not in writing. Many sacred spots in India are associated with their apostolic work.

Rissole' (Fr. *rissoler*, 'to roast brown'), a culinary preparation consisting essentially of fish minced and fried with bread-

crumbs and egg. The preparation presents numerous modifications on that basis.

Ristori, Adelaide, a celebrated Italian actress, was born in the Venetian territory in 1821. Both her parents were comedians, and she appeared on the stage when quite a child. Her first successes were in comedy and light parts, but under the careful training of Carlotta Marchionni she became a proficient in the highest branches of her art. On her appearance in Paris in 1855 she achieved a splendid success, her genius scarcely palling before the brilliant star of Rachel. On the latter's death she was acknowledged her only legitimate successor, and if she lacked the terrible fire and intensity of her great rival, her talents were more versatile and her range of character was wider. Among them are Myrrha, Rosmunda, Medea, Mary Stuart, Phædra, Camma, Francesco di Rimini, and Lady Macbeth. She appeared in Spain in 1857, in Holland in 1860, in Russia in 1861, and in Constantinople in 1864. She has also paid several visits to this country and the United States. She took her farewell of the English stage at Manchester on November 8, 1873. Madame R. married in 1847 the Marquis del Gillo, who died in 1861.

Ritenu'to (Ital.), in music, the lessening of the speed at which a piece is taken.

Rites are the manifestations by outward signs, such as prostrations, genuflexions, &c., of the feelings of reverence, &c., which are inwardly expressed in divine worship. The use of R. is maintained both on historical and internal grounds. 1. Historical, from their universality. 2. Internal, from their adaptation to the constitution of man, so that they are available (1) for purposes of organisation, the sense of a common brotherhood being thereby kept alive among mankind; and (2) for educational purposes: (a) as a mode of imparting the historical truths of religion, and as a constant witness both to (b) doctrinal, and (c) moral truth. R. are also sometimes used as meaning all the ceremonies belonging to a particular religious office, and sometimes even as synonymous with Liturgy (q. v.). See Blunt's *Dict. of Doct. and Hist. Theology* (Lond. 1872).

Ritornell'o (Ital.), in music, a passage or refrain occurring after each repetition of the leading melody—the instrumental symphony played between the different verses of a song.

Ritschl, Friedrich Wilhelm, the greatest classical philologist of the day, was born at Gross-Vargula, in Thuringen, 6th April 1806, and educated at the gymnasia of Erfurt and Wittenberg. He studied at Leipzig under Hermann (1825-26), and at Halle under Reisig, becoming a *privat-docent* in the latter university (1829), and extraordinary professor (1832). In 1833 he accepted a call to Breslau as ordinary professor and joint director of the philological seminary, and three years later undertook a scientific journey to Italy, where he collated MSS., amongst others the famous Codex Ambrosianus of Plautus at Milan. In 1839 he removed to Bonn, which university, as professor of classical philology and eloquence and director with Welcker of the philological seminary, he raised to be the metropolis of what in Germany is styled the 'science of antiquity.' He had already published an edition of Thomas Magister (1832), *De Oro et Orione* (1834), and *Die Alexandrinischen Bibliotheken und die Sammlung der Homerischen Gedichte durch Pisistratos* (1838), but it was at Bonn that he produced his 'epoch-making' edition of Plautus' comedies (3 vols. 1848-54; 2d ed. 1871, *et seq.*), preceded by *Parerga Plautina atque Terentiana* (1845). There, too, he summarised his invaluable researches on Latin inscriptions in the *Præca Latinitatis Monumenta Epigraphica* (6 parts, 1862-64). In 1865 his prosperous career at Bonn was suddenly cut short by the machinations of a colleague, who, representing R. to the Prussian authorities as past his work, forced him to tender his resignation. Nothing daunted, the veteran closed with an offer from the Saxon Government of Hermann's vacant chair, and nobly vindicated his powers by quadrupling the number of the Leipzig students in an incredibly short space of time. He remained in harness to within nine days of his death, which took place on 9th November 1876. Besides the works already mentioned, R. published *Anthologia Latina Corollarium* (1853), *Poesis Saturnina Spicilegium* (1854), *De Varronis Hebdomadum Libris* (1856), 32 collected treatises *Zur Griechischen Literatur* (1866-67), and countless contributions to

philological journals, all marked, says Ihne, 'by perspicuity, a vast range of learning, well-directed research, exhaustive comparison of previous labours, severe logic and sound method, and above all a common sense that never deserted him, and generally led to the discovery of new truths.' The second edition of the comedies of Plautus, left incomplete at R.'s death, is being continued by his pupils.

Rit'son, Joseph, an English antiquary, was born at Stockton in Durham, 2d October 1752, settled in London as a conveyancer, and died 3d September 1803. He was a competent scholar, but an insolent critic, and his opinions in literature were fatally perverted by pride and malignity. Yet some of his works have a permanent value. The chief are *A Collection of English Songs* (3 vols.), *The English Anthology* (3 vols.), *Robin Hood, a Collection of Ballads* (2 vols.), and *A Collection of Scotch Songs* (2 vols.).

Ritt'er, Heinrich, a German philosopher, was born 21st November 1791 at Zerbst, and studied theology and philosophy (1811-15) at Halle, Göttingen, and Berlin. In 1817 he published *Ueber die Bildung der Philosophen durch die Geschichte der Philosophie*, and settled at Berlin. R. was successively appointed an extraordinary professor at Berlin (1824) and an ordinary professor at Kiel (1835) and Göttingen (1837). His chief work is *Geschichte der Philosophie* (12 vols. Hamb. 1829-53; 2d ed. of vols. i. to iii. 1836-38), coming down as far as Kant. The most important of his other works are *Logik* (1824, 2d ed. 1829), *Ueber die Erkenntniss Gottes in der Welt* (1836), *Ueber das Böse* (1839), *Logik und Metaphysik* (2 vols. Goth. 1856), and *Encyclopädie der Philosophischen Wissenschaften* (3 vols. Göt. 1862-64). His *Kleine Philosophischen Schriften* (3 vols. Kiel, 1839-40) chiefly relates to questions of æsthetics and the philosophy of law. R. is best known in England by the *Historia Philosophiæ Græcæ et Romanæ* (Hamb. 1838; 5th ed. Gotha, 1875), which he wrote in conjunction with Preller (q. v.). He died at Göttingen, 3d February 1869.

Ritt'er, Karl, a celebrated German geographer, was born at Quedlinburg, 7th August 1779, attended the university of Halle, and at Göttingen made a special study of ancient history. In 1820 he was appointed professor of geography in the university and military school of Berlin, and in 1822 a member of the Academy. He is the founder of the so-called science of comparative geography, and the author of many learned works, of which the principal are *Die Erdkunde im Verhältnisse zur Natur und Geschichte des Menschen* (2 vols. 1817; 2d ed. extended 1822-59, to 19 vols.), *Die Stupas, oder die Architektonischen Denkmale an der Indo-Baktrischen Königstrasse und die Kolosse von Barmyram* (1838), and *Einleitung zur allgemein-vergleichenden Geographie* (1852). He died at Quedlinburg, 29th September 1859. Of his valuable and voluminous memoirs published in the Transactions of various societies, his pupil Daniel issued separately *Geschichte der Erdkunde und der Entdeckungen* (1861), *Allgemeine Erdkunde* (1862), and *Europa* (1863). To his memory were founded the K. R. Stiftungen in Berlin (1860) and Leipzig (1861), which have for their object the encouragement of travel and scientific work. See the Biographies of R. by Gage (Lond. 1867) and Kramer (2 vols. Halle, 1864-70).

Rit'ual, in its general sense, means the body of Rites (q. v.) employed at any time in the Church. Specially it means the service-book containing the minor sacramental and other offices which might be performed by the inferior clergy, as distinguished from the Pontifical (q. v.). Originally each bishop had the power to form his own liturgy and R., provided he retained the essential features of the worship of the time. In the 5th c. the Metropolitan Liturgy and R. became the standard for each province; and in the 7th c. these were superseded by national ones. In England the diocesan system prevailed till 1549, when the national Book of Common Prayer (q. v.) was compiled. See Blunt's *Dict. of Doct. and Hist. Theol.* (Lond. 1872).—The name *Ritualism* is popularly given to the remarkable development of ceremonial worship which has taken place in the Church of England during the last thirty years, and which threatens to disrupt that ancient and powerful institution.

Rive-de-Gier, a town of France, department of Loire, on the river Gier, 13 miles N.E. of St. Etienne by rail. A canal, supplied with water from the immense basin of Couson, which

holds 1,500,000 cubic metres, connects R. with Givors on the Rhone. R. is in the centre of a coalfield containing 52 pits, and producing yearly about 659,000 tons of coal. It has 30 glassworks, employing 1200 workmen, and producing over 4,000,000 francs annually, and has also foundries, manufactures of machinery, steel-works, brickworks, and silk-mills. Pop. (1872) 13,946.

River (Fr. *rivière*, from Low Lat. *riparia*, belonging to the *ripa*, or 'bank'). Under the heading RAIN, the natural processes by which the vapour drawn up from the ocean into the air by the action of the sun's heat is condensed into clouds and then discharged upon the earth's surface are described and explained. It remains to complete the natural history of the cycle of operations by which the ocean receives again the waters it had lost; and rivers are the chief channels by which these waters return. Of the rain which falls upon the earth's surface, part drains directly away and helps to swell the volume of some neighbouring river or lake, and part is evaporated; but the greater portion sinks into the porous ground, percolates through the subsoil and underlying formations, and after this filtering process collects in some earth cavity, whence it finds ultimate outlet as a spring. Or, condensing on the cold peaks of a mountain-system, the vapour assumes the form of snow, which, squeezing its way into the lower clefts and valleys, consolidates into glaciers; and from the lower extremities of these issue countless mountain-rills, which pour their muddy waters into R. or lake. The two great sources of rivers are, then, springs and glaciers; for even should a R. appear to have its source in a lake, this lake, if it be not itself fed by minor streams, is nothing more than the expansion of a spring, an expansion which is simply the result of the configuration of the surface. As a general rule, rivers terminate in a sea; and all the really important rivers do. Certain rivers, however, flow into an inland lake, such as Lake Tchad in Africa, the Caspian and Dead Seas in Asia, and the Great Salt Lake in America. These lakes are always salt, and gaining in saltiness, for the same reason that the sea is salt. The saline substances present in any mass of water do not evaporate; while any running water carries along with it in solution whatever soluble saline substances it may have come across on the way. For these reasons, a sea or inland lake cannot lose any of its saltiness, but is continually receiving from the rivers which flow into it small accessions of salt solutions. There is still a third class of rivers which have no outlet to sea or lake. These are lost in marshes or sandy deserts, being evaporated faster than they are supplied. They are common in the central plains of Asia.

All the rills, streams, and rivulets which ultimately gather into one broad R. form a R. system; and the region of country which is drained of its superfluous waters by such a system is called the R. basin. Basins are usually separated from each other by mountain ranges; and the imaginary line of demarcation between these basins is known as the *watershed*. Not only do rivers serve for draining a country, but they act as important geological agents. As already indicated, they act chemically upon various mineral substances, which are borne down towards the sea in solution. This action, however, is unimportant compared to the purely mechanical action of running water. Fragments of rock, from boulders to the finest mud particles, are carried down the stream until the energy of the current becomes too small to effect the transportation. This continual drawing away of material results in a simultaneous widening and deepening of the channel in which the water flows. The rate at which this erosion takes place depends very much upon the nature of the land-surface; but even when the erosion is very slow, the evidences of its existence are undoubted. Ravines, gorges, cañons, &c., have been formed almost wholly by the streams which now flow through them; but this denudation is not so much due to the direct action of the water as to the wearing and tearing action of the matter it holds in suspension. The detritus, then, which is borne down the stream, is itself the great eroding agent; and as the R. broadens and deepens and slackens in speed, the suspended fragments gradually fall to the bottom, the heavier ones first, and the lighter ones later. Thus a R. in its early courses bounds over abraded rocks and massive boulders; but as it descends to lower regions and gentler declivities, its bed contains less massive fragments, which pass through all gradations from good-sized pebbles to worn gravels. And when at length the stream reaches the ocean, the gravel beds have

passed insensibly into sandbanks, and these into mudbanks. At the mouths of rivers, accordingly, accumulations of sand and mud are continually being deposited. These accumulations are known as deltas, and are well marked in the cases of the Po, Rhine, Nile, Ganges, and Mississippi. Rivers which, like the Thames, are exposed to full tidal action, do not form deltas. In many such cases, a *bar* or shoal is thrown across the mouth of the estuary, which interferes with navigation. The two largest known rivers, the Amazon and Congo, have no deltas, but sweep out into the ocean in an unbroken stream. The rich alluvium which is deposited along the banks of certain rivers is brought down during the periodical inundations, which are especially characteristic of tropical rivers. The inundations of the Nile are world-famed, and far more extensive are the annual floodings of the banks of the Amazon. The Amazon is unquestionably the greatest R. on the globe, having a drainage area of 2,831,500 sq. miles, and a length (exclusive of windings) of 3070 miles. The Mississippi-Missouri is longer (4234 miles), but its basin has an area of only 1,244,000 sq. miles. The Obi, in Siberia, has a length of 2600 miles, but in drainage area it is second only to the Amazon, 1,300,000 sq. miles. The Nile again, though it exceeds the Amazon in length (3500 miles), drains a comparatively contracted area, which, though it has not yet been definitely valued, does not probably exceed one million sq. miles. The Livingstone or Congo-Lualaba drains, according to Petermann, as much as 1,256,000 sq. miles, including the basin of Lake Tanganyika, which Stanley believes to have a periodical outflow to the lake system of the Lualaba. See *Physiography*, by Professor Huxley (Lond. 1878).

Law Regarding Rivers.—The right in flowing water is, by English law, public. The legal presumption is that the owner of each bank of a stream is the owner of one half of the bed over which it flows; but the water belongs to neither. No riparian owner has a right to pollute the water without the consent of all the others. No owner has a right to do any act by which the supply of water is lessened to the lower owners, nor by which the stream is made to overflow the land above. The only way in which a preferable right to the use of running water can be acquired are by licence from the person or persons whose rights are affected, or by twenty years' unchallenged use of the privilege claimed, which gives a title by *Prescription* (q. v.). Each owner has a right to the fish in his share of the river in England; but in Scotland, the salmon and right of salmon-fishing do not necessarily belong to the riparian owner (see SALMON and SALMON-FISHING, LAWS REGARDING). Navigable rivers are *inter regalia*, and are held by the Crown in trust for the community. If the right of navigation interfere with that of fishing, the latter must yield.

River Crab, the name given to a species of the genus *Thelphusa*, included in the *Decapodous* order of the Crustacean class. It is also named the 'Mud Crab,' from its habit of burrowing in the mud of rivers. The *T. depressa*, or Flattened Mud Crab, is the 'Grancio' of the Italians, and is common around Rome, its flesh being regarded as exceedingly delicate. It can be removed from the water for a lengthened period. The R. C. abounds in the Lake of Albano. *T. cunicularis* is a common Indian species. In the family to which the R. C. belong, the carapace or shell is oval in shape, and the stalks of the eyes are short. The body in the genus *Thelphusa* is broad, smooth, flat, and somewhat heart-shaped. The outer pair of feelers are short, and placed near the eyes.

Rivers and Streams, Pollution of. The first sanitary Act in the English statute-book was a Rivers' Pollution Act; for in the year 1388 an Act was passed imposing a penalty of £20 upon persons casting animal filth and refuse into rivers. In 1865 and 1868 respectively, Royal Commissions were appointed to investigate the P. of R. and S., and report thereon; but although the magnitude of the evil, the polluting agencies, and the appropriate remedial measures were clearly pointed out, legislation on the subject was delayed until August 1876, when 'An Act for making further Provision for the Prevention of Pollution of Rivers' was passed. The substances polluting rivers are organic and inorganic. The organic substances are sewage and the effluent drainage waters from cotton and other mills; from print, dye, bleach, alkali, chemical, soap, starch, and other works; tanneries, distilleries, &c. Such effluents all hold in suspension and solution matters principally organic and more or

less putrescent. The inorganic substances are chiefly those arising from mining operations and metal manufactures. In the case of lead, zinc, copper, arsenic, tin, and baryta mines, a directly poisonous ingredient is added to the water, some part of which is dissolved, the remainder being held in suspension. In some instances, the affluent waters are extremely acid and corrosive, so much so that they destroy the cement and brickwork of sewers.

The Rivers Pollution Prevention Act, 1876, consists of six parts, as follows:—Part I. *Law as to Solid Matters* prohibits the putting solid matter into streams, such as the solid refuse of any manufactory, manufacturing process or quarry, or any rubbish or cinders, or any other waste or any putrid solid matter. In proving interference with the due flow of any stream, or in proving the pollution of any stream, evidence may be given of repeated acts which together cause such interference or pollution, although each act taken by itself may not be sufficient for that purpose.

Part II. *Law as to Sewage Pollution* prohibits the drainage of sewers into streams. 'Every person who causes to fall, &c., into any stream any solid or liquid sewage matter, shall be deemed to have committed an offence against this Act.' 'Where any sewage matter falls, or flows, or is carried into any stream along a channel used, constructed, or in process of construction at the date of the passing of this Act, for the purpose of conveying such sewage matter, the person causing or knowingly permitting the sewage matter so to fall or flow or to be carried shall not be deemed to have committed an offence against this Act if he shows to the satisfaction of the court having cognisance of the case that he is using the best practicable and available means to render harmless the sewage matter so falling, or flowing, or carried into the stream.' Where the court is satisfied that further time ought to be granted to any sanitary authority for the purpose of enabling such authority to adopt the best practicable and available means for rendering harmless such sewage matter, the court may declare that this section shall not, so far as regards the discharge of sewage matter by such channel, be in operation until the expiration of a period to be limited in the order; and the order may from time to time be renewed by the court, subject to such conditions, if any, as it may see fit.

Part III. *Law as to Manufacturing and Mining Pollutions*, prohibits the drainage from manufactures into streams. 'Every person who causes to fall, or flow, &c., into any stream any poisonous, noxious, or polluting liquid proceeding from any factory or manufacturing process, shall be deemed to have committed an offence against this Act.' When the best practicable and reasonably available means are used to render the polluting liquid harmless, no offence is committed. Under this section there is a very important restriction on proceedings; for proceedings cannot be taken against any person under this part of the Act save by a sanitary authority, nor can any such proceedings be taken even by a sanitary authority without the consent of the court having cognisance of the case; provided always that if the sanitary authority, on the application of any person interested alleging an offence to have been committed, shall refuse to take proceedings, or apply for the consent by this section provided, the person so interested may apply to the court having cognisance of the case, and if that court on inquiry is of opinion that the sanitary authority shall take proceedings, they may direct the sanitary authority accordingly, who shall thereupon commence proceedings. It is also enacted that any person within such district as aforesaid, against whom proceedings are proposed to be taken under this part of this Act, shall, notwithstanding any consent of the Local Government Board, be at liberty to object before the sanitary authority to such proceedings being taken, so far as the same relates to his works or manufacturing processes. The sanitary authority shall thereupon allow such person to be heard by himself, agents, and witnesses, and after inquiry, such authority shall determine, having regard to all the considerations to which the Local Government Board are by this section directed to have regard, whether such proceedings as aforesaid shall or shall not be taken, and where any such sanitary authority has taken proceedings under this Act, it shall not be competent to other sanitary authorities to take proceedings under this Act till the party against whom such proceedings are intended shall have failed in reasonable time to carry out the order of any competent court under this Act.

Part IV. *Administration of Law* authorises sanitary authorities

to afford facilities for factories draining into sewers, and empowers sanitary authorities to enforce the provisions of the Act in relation to any stream being within or passing through or by any part of their district.

Legal Proceedings, Saving Clauses, Definitions.—The county court may by summary order require any person to abstain from the commission of such offence, and when there is default to perform a duty under this Act, may require him to perform such duty, and if either party feel aggrieved he may appeal to the High Court of Justice. 'Stream' includes the sea to such extent, and tidal waters to such point, as may, after local inquiry and on sanitary grounds, be determined by the Local Government Board, by order published in the *London Gazette*. Save, as aforesaid, it includes rivers, streams, canals, lakes, and watercourses, other than watercourses at the passing of the Act mainly used as sewers, and emptying directly into the sea, or tidal waters which have not been determined to be streams within the meaning of this Act by such order as aforesaid.

Part V. *Application of the Act to Scotland.*—The terms 'Local Government Board' and 'Secretary of State' shall mean one of Her Majesty's Principal Secretaries of State, and 'High Court of Justice' shall mean the Court of Session.

Part VI. makes provisions for the application of this Act to Ireland.

River Terraces occur along the sloping banks of certain rivers, and mark the height at which the river formerly flowed. They are thus somewhat analogous to raised beaches both in their appearance and mode of formation. They are found along the Rhone, Severn, Seine, &c.

Rivet (Fr.), a short metal bolt, consisting of a head, neck, and shank, employed for uniting two overlapping plates of metal or other material. Rivets used in iron shipbuilding and boiler-making, &c., are made from a superior quality of iron by machinery. The head of a 'pan-head' R. is flat, and that of a 'snap-head' hemispherical. When required for use the R. is made red hot, and inserted in the drilled or punched holes prepared for it in the plates; a workman then presses heavily against the head with a hammer, while two 'riveters' beat down or clench the other end, forming a conical point, a 'countersunk' (for a flush surface), or a 'snap,' as may be required. To form the snap-point, the end of the R. is covered with a cup-shaped die, but the other two kinds are formed directly with the hammer. Riveting machines, on the general principle of the punching-machine, have been in use for several years, and for some kinds of work give great satisfaction. Sir William Fairbairn of Manchester first introduced them, and his machines and Tweddell's hydraulic riveters are extensively employed.

Riviera (Ital. 'coast,' from Low Lat. *riparia*), the beautiful strip of shore on the Gulf of Genoa, from Nice to Spezzia, traversed by the famous Route de la Corniche, and by a continuous line of railway, opened in 1814, which is carried through 80 tunnels and many cuttings. To the E. of Genoa it is known as R. di Levante, to the W. as R. di Ponente. The road passes precipitous cliffs, washed by the Mediterranean surf and crowned by ruined castles, skirts extensive plantations of olives and bright green pine-forests, and is bordered by luxuriant growths of figs, vines, citrons, oranges, oleanders, myrtles, aloes, and even palms. Towns are perched like nests among the rocks, and their churches peer forth from a sombre setting of cypresses, while gigantic pinnacles of rock rise abruptly from the rich coast-plain.

Rivoli, a town of N. Italy, province of Torino (Turin), 9 miles W. of Turin by rail. It has a royal residence, and manufactures of silks, woollens, linens, and needles. Pop. (1874) 4886.—**R.**, a village in the Italian province of Verona, between the Lago di Garda and the right bank of the Adige, 12 miles N.W. of Verona by rail, where the Austrians under Wurmser were defeated by the French under Bonaparte, 14th and 15th January 1797. Massena, for his exploits here, was afterwards named Duc de R.

Rizah, a town of Asiatic Turkey, on the Black Sea, 35 miles E. of Trebizond. It has extensive linen manufactures. There are nearly 30,000 male inhabitants in the district.

Rizzio. See RICCIO.

Roach (*Leuciscus rutilus*), a species of Teleostean fishes belonging to the Carp family, and common in freshwater lakes and rivers. The R. generally swims in shoals, and is a fish requiring considerable dexterity to capture. It is rather sensitive to changes in temperature and weather. The average weight is about $\frac{1}{2}$ lb. The colour is a greyish green tinted with blue, the abdomen being silvery white. The fins are bright red, the dorsal and tail fins brownish red.

Road, in law. See HIGHWAYS, LAW REGARDING.

Roads and Road-Making. A road is a line of communication between any two points fitted for foot-passengers, cattle, and vehicles. Roads are not only most characteristic essentials of civilisation and commerce, but in themselves they exercise a powerful influence in breaking down barriers of suspicion and jealousy among tribes and peoples, and they directly promote the spread of knowledge, goodwill, and mutual helpfulness among communities separated from each other. The abundance and excellence of roads in any country forms a pretty fair criterion of the civilisation, importance, and wealth of the people owning them, and in that view the following figures possess interesting significance:—

LENGTH OF METALLED ROADS IN 1868-69.

Country.	Length of Roads. Miles.	Area. Sq. miles.	Population.
United Kingdom .	160,000	122,519	30,621,431
France	100,048	210,460	38,192,064
Prussia	55,818	130,675	23,970,641
Spain	20,886	198,061	15,673,481

The ordinary highways of the country were, down to the early part of the present century, in a most unsatisfactory condition, so that communication between towns apart was very slow, dangerous to passengers, and painfully difficult to the horses which had to drag the heavy and lumbering vehicles fitted for the roads. A very graphic sketch of the condition of British roads during the 18th c. may be found in Smiles *Lives of Engineers*, vol. i. Mr. Arthur Young writing in 1770 uses some exceedingly strong language regarding the condition of various roads. Writing of the road to Wigan he says:—'Turnpike—I know not in the whole range of language terms sufficiently expressive to describe this infernal road. Let me most seriously caution all travellers who may accidentally propose to travel this terrible country to avoid it as they would the devil, for a thousand to one they break their necks or their limbs by overthrows or breakings down. They will here meet with ruts, which I actually measured 4 feet deep, and floating with mud only from a wet summer; what therefore must it be after a winter? The only mending it receives is tumbling some loose stones, which serve no other purpose than jolting a carriage in a most intolerable manner. These are not merely opinions but facts; for I actually passed three carts, broken down, in those 18 miles of execrable memory.' The condition of public roads even so late as 1809 was little better than that pictured by Mr. Young. The theory of roadmaking was to pile up loose materials in the middle of the way, so that the road was almost barrel like, and thus its sides formed steep and dangerous slopes. Carriages were therefore forced to keep in the middle of the way and thus deep ruts were formed, which gathered the water and forced the loose materials outwards to the sides, quickly converting the convexity to a concavity as seen in the section fig. 1. Towards the end of

Fig. 1.

autumn the repair of a road in such a condition would be undertaken, the loose material again would be pitched into the centre,

more unassorted stones, &c., would be thrown over the surface, and the barrel-like appearance (fig. 2) would once more be pre-

Fig. 2.

sented. Winter's storms and summer's traffic very soon told on its specious and insecure rotundity, and the last end of that road (fig. 3.) would be worse than its first.

Fig. 3.

There is a good deal of dispute as to whom should be assigned the credit of introducing the system of road-making now known as Macadamisation. The method takes its name from Mr. James L. Macadam, who at any rate was undoubtedly the first to put it into extensive practice. In 1816 that gentleman, then in charge of the Bristol roads, put into operation the plan associated with his name, viz.,—to put broken stone upon a road which shall unite by its own angles to form a solid, hard surface. 'It follows,' Mr. Macadam stated before a select Committee of the House of Commons in 1819, 'that when that material is laid upon the road, it must remain in the situation in which it is placed without ever being moved again.' As examples of engineering skill, no roads in the United Kingdom equal the system laid down by Mr. Telford about the beginning of the century in the Highlands of Scotland and in other localities.

Roads as now made are kept as flat on the surface as is consistent with the running of the surface water to the sides. The consolidation of road metal on the surface is also greatly promoted by the use of heavy steam rollers after fresh metalling. Under and side drainage is of the most essential consequence to the quality and durability of a road. The accompanying section, fig. 4, is that of a first class highway with a footpath A, side-

Fig. 4.

channel B, with an opening into a drain C, a roadway D, and a ditch E, on the other side of the road. Regarding the use of surface materials other than 'metal' or broken stones for roads, streets, and footpaths, see PAVEMENT.

Roanne, a town of France, department of Loire, 49 miles N.N.W. of St. Etienne by rail, on the left bank of the navigable Loire, and connected by the Canal-de-Digoin with all the principal water-roads of France. The *Rodumna* of the Segusians, it has remains of baths and a Gallo-Roman cemetery, whilst the church of St. Etienne, dating from the 12th c., a ruined chateau, and the college founded by Henri IV.'s confessor, the Jesuit Cotton, constitute its chief historical monuments. Cotton-mills employ 1200 workpeople, and there are also tanneries, dye-works, faience and hat factories, &c. Pop. (1872) 18,251.

Roanoke, a river of N. America, 260 miles long, formed by the junction of the Dan and Staunton at Clarksville, Virginia, flows through that State and N. Carolina until it reaches the sea at Albemarle Sound. It is tidal up to Halifax Falls, 75 miles

from its mouth, and navigable for steamboats as far as Weldon, 75 miles farther up.

Roaring, the name given to a peculiar affection of the respiratory organs of the horse, characterised by a roughened or grating noise during inspiration. It appears to consist of a spasmodic action of the muscles of the larynx and bronchial tubes, and is attended with atrophy or wasting of the muscles of the larynx. The affection constitutes legal unsoundness in a horse. It increases with time, and appears to be a result of cold, strangles, chest inflammation, &c. A 'R.' horse should be fed and watered several hours before work. In bad cases tracheotomy has been performed, the horse sometimes working for a long period afterwards.

Roasting, a mode of cooking food in front of a fire. As in the process of boiling meat, to retain the nutritive juices inside it, meat to be roasted should first be subjected to a sharp heat for a few minutes in order to coagulate the albuminous matter on the outside and thereby prevent the escape of the internal fluids. The meat ought then to be withdrawn from the fire to such a distance as will allow of the inner portions being slowly and gradually penetrated by the heat. This process of slow R. renders the muscular fibres easy of mastication, coagulates a portion of the albumen and fluids inside, and develops, owing to obscure chemical changes, the well-known savoury flavour and odour of roast-meat.

R., in metallurgy, signifies the protracted heating of metallic ores in order to dissipate volatile matters, and sometimes to effect oxidation.

Rob (Arab. *rob*, 'inspissated juice'; Ital. and Span. *rob*), a term used principally in pharmacy for a conserve prepared by mixing the juice of ripe fruit with honey or sugar.

Robbery, in law, is theft from the person (see LARCENY or THEFT), aggravated in criminality by violence or intimidation in execution. The value of the article taken is immaterial. Forcibly to take a penny is as criminal as forcibly to take a pound. To snatch or filch from the person, though criminal, is not R. The law regarding this crime has been consolidated and amended by 24 and 25 Vict. c. 96. It is declared felony; the punishment ranging from two years' imprisonment to fourteen years' penal servitude, according to circumstance.

Robert I. See BRUCE.

Robert II., the first of the Stewart house to ascend the Scottish throne, was the son of Walter Stewart and Robert Bruce's daughter Majory. He was born March 2, 1316, and played an important part during the minority and exile of David II., acting as regent, and being present at the battles of Halidon Hill and Neville's Cross. He was fifty-five years old when he ascended the throne, but in that position he felt powerless to restrain his turbulent barons—Douglas, Mar, March, Moray, and the rest—who embroiled him continually with England. In 1381 John of Gaunt, Duke of Lancaster, marched to the border, and imposed on the Scots a three years' truce. At the end of that truce the French sent into Scotland a body of 2000 men under Jean de Viennne, who brought arms and money to tempt the nobles to invade England. The nobles yielded to the temptation, and the allies ravaged the N. of England, but soon disagreed among themselves, and returned home. In 1388 a fresh invasion was begun under the leadership of young Douglas, and this ended in the famous battle of Otterburn (see CHEVY CHASE). In the following year the aged king appointed his second son, the Earl of Fife, to govern in his stead. R. died at Dundonald Castle, Ayrshire, 19th April 1390. He was a monarch who allowed his nobles to manage his kingdom and his mistresses to manage his private affairs.—**R. III.**, eldest son of the preceding, born about 1340, was crowned at Scone, August 14, 1390. His original name was John, and some say it was changed because of its association with Baliol. He inherited his father's indolent disposition, although a better man, and left the power almost entirely in the hands of his designing brother, the Earl of Fife. The Earl was created Duke of Albany in 1398, and the King's son, Earl of Carrick, was then made Duke of Rothesay. These were the first Scottish Dukes. The truce with England, which had remained unbroken during the earlier years of Robert's

reign, was broken in 1400 by Henry IV., who marched with an immense army to Leith, but was forced by want of provisions to return without striking an effective blow. Next year Albany persuaded the King that the profligate Rothesay should be kept under restraint, and imprisoning his nephew in Falkland Castle, he starved him to death. In 1402 the Scots were defeated at Homildon Hill, and in 1405 the King's second son, James, in attempting to escape to France, was captured by the English at Flamborough in Yorkshire. This calamity fairly broke the spirit of the King, who died at Rothesay, April 4, 1406. See Hill Burton's *History of Scotland*.

Robert of Gloucester. See GLOUCESTER, ROBERT OF.

Roberts, David, B.A., the greatest English architectural painter, was born at Stockbridge, Edinburgh, 24th October 1796. He was the son of a working shoemaker, and while a mere child evinced an intense love of pictures, and precocious skill as a copyist with chalk or burnt 'spunks.' During a seven years' apprenticeship to house-painting, he steadily practised drawing and painting, and deepened his devotion to art by fellowship with a host of young aspirants, together with whom he opened three or four annual exhibitions of pictures. After a pleasant and studious year at Perth as a foreman house-decorator, he returned to Edinburgh to begin his career as a scene-painter in 1816, and accompanied a strolling company as far as York. After a varied and arduous experience, enlivened by gleams of success, he was appointed scene-painter in the Edinburgh Theatre Royal in 1820. He exhibited small pictures first at the Edinburgh Exhibition of 1821, and gained much from an intimate acquaintance with Clarkson Stanfield, whom he joined as a *collaborateur* in scene-painting at Drury Lane in 1822. Two years later he exhibited 'Dryburgh Abbey' in the collection of the British Institution, and in 1825 sought on the Continent for newer and higher subjects. His first picture at the Royal Academy was 'Rouen Cathedral' (1826), on seeing which Turner remarked to Sir W. Allan, 'Here is a man we must have our eye upon.' Devoting himself wholly to architectural painting, he produced his fine illustrations of Bulwer's *Pilgrims of the Rhine* in 1832, travelled through Spain in 1832-33, and issued *Picturesque Views in Spain* (1837), and brought his reputation to a height by his memorable journey in the East, the immediate result of which was the splendidly illustrated *Holy Land, Syria, Idumea, Arabia, Egypt, and Nubia* (4 vols. 1842-49). Meantime he had been made an Associate in 1838, and an Academician in 1841, while subsequently he received many honours, the last being the freedom of the City of Edinburgh in 1858. R. died in London, 25th November 1864. His wonderful industry may be judged from the fact that, besides theatrical scenes and prints, he produced nearly 300 finished pictures and some 11,000 sketches in oil and water-colour. A sale of the latter after his death realised £17,000. Admirable specimens of R.'s best style are the 'Ruins of Baalbec' (1841), 'Temple of Karnac' (1845), 'Destruction of Jerusalem' (1849), 'Venice' (1852), 'Interior of St. Peter's' (1854), 'Rome' (1855), 'Temple of the Sun, Baalbec' (1861), 'Mausoleum of Hadrian' (1863). Thackeray, a fast friend of R., says his 'hand is the perfect and accomplished slave of his intellect, and ready, like a genius in an Eastern tale, to execute the most wonderful feats and beautiful works with the most extraordinary rapidity.' His facility in the attainment of broad, powerful effects is equalled by his faultless fidelity in the treatment of subjects ranging from the most gorgeous interior to the airy heights of Lebanon, and from ambitious Gothic piles to the vast Theban ruins. See *Life of R., compiled from his Journals*, by James Ballantyne (Edin. 1866).

Robertson, Frederick William, was born in London, February 3, 1816. He was the son of a Scotch gentleman, Captain Frederick R., of the Royal Artillery, and the first five happy years of his life were spent in Leith Fort. He was educated for some time at the grammar-school of Beverley, in Yorkshire, accompanied his parents to the Continent for a year, during which he secured an accurate acquaintance with the French language, and at the age of sixteen he entered the Edinburgh Academy. At the Academy he won all but the highest honours; and from that institution he passed for a brief session to Edinburgh University. Destined by his father for the bar,

he himself nourished the hope of entering the army. The chivalry of his nature had already been abundantly manifested at school: 'I was rocked and cradled,' he writes, 'to the roar of artillery.' In the end, however, he entered Brazenose College, Oxford (1836), and proceeded to holy orders. In 1840 he was ordained at Winchester by the bishop of the diocese, and obtained the curacy of St. Maurice and St. Mary Calendar in that city. He began work in the spirit of an ascetic, and so weakened mind and body that he had to seek rest on the Continent at the end of a year. At Geneva he married the daughter of an English baronet. Returning to England, he took duty at Cheltenham as curate to the Rev. Archibald Boyd. In this position he remained for five years, but at the end of that time the crisis of his life occurred. He had hitherto called himself an Evangelical, and now he found himself no Evangelical. Like Jouvroy, he found his old beliefs 'slip from him like a garment.' The spiritual fascination exerted by certain of the Tractarians over him faded before the light of reason, and towards the greater portion of his party he began to conceive the bitterest dislike. 'They tell lies in the name of God; others tell them in the name of the devil:—such were the words with which he tore himself from those who shared his early faith. He threw up his curacy at Cheltenham, and led a lonely life for some time in the Tyrol and at Heidelberg. In 1847 he came back to England, and undertook the charge of St. Ebbes, Oxford. Two months after, he removed to Trinity Chapel, Brighton, where he spent the remaining six years of his life. The intensely practical tone of his preaching took hold not more of the aristocratic circles at Brighton than of the working classes. He preached charity as no other English divine has ever preached it. He determined to make Christianity 'bear upon the social state of all parties; upon the questions which agitated society; upon the great movements of the world.' Therefore he worked among his people not only in the pulpit, but on the platform, meeting Chartists and infidels on their own terms, believing ill altogether of nobody and no class; seeking 'to judge the world and to estimate the world's maxims as Christ judged and estimated.' His catholicity prevented his union with any separate school, and prevented him also from founding a school. No man of so sensitive a nature suffered more narrow-minded persecution on account of doctrine; but no man has won more admiration from his enemies. His nature was full of Christian chivalry; and throughout all cultivated society in the land a new religious energy, spiritual and not less rational, has been developed by his preaching, by the teaching of his books, and above all by the story of his pure life. He died, a broken-down man, in his thirty-seventh year, August 14, 1853. Four series of his *Sermons* have been published (1855-73). His *Expository Lectures on St. Paul's Epistle to the Corinthians* appeared in 1859; *Lectures and Addresses on Literary and Social Topics* followed in 1858; an *Analysis of Tennyson's 'In Memoriam'* in 1862; and *Notes on Genesis* were edited in 1877. The Rev. Stopford Brooke has written a fine Life of his friend (1865).

Robertson, James Craigie, born in 1813 at Aberdeen, proceeded from the Marischal College to Trinity College, Cambridge, where he graduated (1834). Having taken Anglican orders, he became vicar of Bekebourne, Kent (1846), was made a canon of Canterbury (1859), and received the chair of ecclesiastical history in King's College, London (1864), which he held till 1875. R. has written *A History of the Christian Church* (1853; new ed. 8 vols. 1873-75), *Sketches of Church History, First Six Centuries* (1855), and *Becket, Archbishop of Canterbury* (1859), a biography whose general accuracy is marred by a pervading tone of hostility. He has also edited Heylyn's *History of the Reformation for the Ecclesiastical History Society*, Bargrave's *Alexander VII. and his Cardinals* for the Camden Society, and for the Record Office *Materials for the History of Thomas Becket* (vols. i.-ii. 1875-76).

Robertson, Joseph, a distinguished Scottish antiquary, born at Aberdeen, 17th May 1810, educated at the grammar-school there and at Marischal College, went to Edinburgh in 1833, and was for some time engaged in miscellaneous literary work. From 1839 to 1843 he edited the *Aberdeen Constitutional*, from 1843 to 1849 the *Glasgow Constitutional*, and from 1849 to 1853 the *Edinburgh Evening Courant*. In 1853 he was appointed Curator of the Historical Department of the Register House, Edinburgh, an office which he held till his death, 13th 390

December 1866. R. was a most laborious student, and a most cautious, shrewd, and penetrating critic. His work is among the best of its kind done in any country. In conjunction with Mr. John Stuart he founded the Spalding Club in 1839. The principal works written or edited by him are *The Book of Bon Accord, or a Guide to the City of Aberdeen* (1839); for the Spalding Club, Gordon of Rothiemay's *History of Scots Affairs from 1637 to 1641*, edited in conjunction with Mr. Grub (3 vols. 1841); *Collections for a History of the Shires of Aberdeen and Banff* (1843); *Illustrations of the Topography and Antiquities of the Shires of Aberdeen and Banff* (3 vols. 1847-62); for the Maitland Club, *Book of the Collegiate Church of St. Mary and St. Anne, Glasgow* (1846), and *Chartulary of the Black Friars of Glasgow* (1846); for the Bannatyne Club, *Catalogues of the Jewels, Dresses, Furniture, Books, and Paintings of Mary Queen of Scots* (1863), with an admirable historical preface; and the *Concilia Scotie* (2 vols. 1866), also edited for the Bannatyne Club, and regarded as his most important contribution to archaeological literature.

Robertson, Thomas William, a brilliant modern dramatist, was born at Spalding, in Lincolnshire, 9th January 1829. He was born, as it were, on the stage; in his own phrase, 'was nursed on rose-pink and cradled in properties.' His father and mother both earned some theatrical reputation, and his sister, Madge R. (now Mrs. Kendal), subsequently became one of the brightest ornaments of the famed Haymarket company. R. himself failed as an actor in the provinces, and settled in London as a journalist in 1860. After much literary drudgery, he became dramatic critic to the *Illustrated Times*, and a contributor to the best of the lighter periodicals. Meantime he had written and translated many plays, but it was not till after many delays and disappointments that he achieved his first triumph as a dramatist on the production of *Society* at the Prince of Wales' Theatre in 1865. This success he followed up with *Ours* in 1866, *Caste* in 1867, *Play* in 1868, *School* in 1869, and *M.P.* in 1870. These comedies, aptly called cabinet pictures of society, are all characterised by unwonted freshness and realism, and in scarcely a less degree by arch humour and dramatic effect. The plots, in their simple, flimsy structure the reverse of 'sensational,' are sustained by the strong element of well-balanced *dramatis personæ*, and enlivened by delightful idyllic situations. Recoiling from mock heroics and staginess, R. has been taxed with the opposite evil of commonplace, but the real faults of his art are those of the everyday life he depicts—a shallow cynicism, occasional vulgarity, and a tendency to 'chaff' or 'verbal wit,' but these are atoned for by the presence of genuine poetic feeling. R. died in London, 3d February 1871.

Robertson, William, an illustrious Scottish historian, was born in the manse of Borthwick, county of Mid-Lothian, September 19, 1721. His father removed to Edinburgh as minister of Old Greyfriars' Church, and William commenced university studies at the age of twelve. At the age of twenty he was licensed to preach, and two years afterwards the Earl of Hoptoun presented him to the parish of Gladsmuir, Haddingtonshire. Nothing in R.'s life redounds more to his credit than the fact that in the manse of Gladsmuir, with a stipend of only £100, he supported and educated six orphan sisters and a brother; and only on reaching his thirtieth year, when they were all comfortably established in life, did he himself marry. He early became a noted debater in church courts, and on such questions as that of lay patronage took up so decided a position as ere long to be looked to as leader of the moderate party in the General Assembly. In 1775 his predilection for historical inquiry was manifested in the title of the only sermon he ever published—*The Situation of the World at the Time of Christ's Appearance, and its Connection with the Success of His Religion Considered*. Shortly after this R. distinguished himself as the defender of Home, whose tragedy of *Douglas* caused such scandal in ultra-Calvinistic circles. In 1759 appeared his *History of Scotland during the Reigns of Mary and James VI., till his Accession to the Crown of England*. This work, which occupied two quarto volumes, was sold by the author for £600, and congratulations upon its success reached him from the most distinguished men of the day. R. was now appointed garrison chaplain at Stirling; in 1761 he became a Dean of the Chapel Royal; in 1762 he was raised to the Princi-

palship of Edinburgh University, uniting the duties of that post with those of minister of Old Greyfriars; and two years later he was nominated historiographer of Scotland, with a salary of £200. In 1769 he published *The History of the Reign of the Emperor Charles V., with a View of the Progress of Society from the Subversion of the Roman Empire to the Beginning of the Sixteenth Century* (3 vols. 4to). The copyright of this work brought £3600. Eight years afterwards, his *History of America* (2 vols. 4to) added still to his fame. He laboured for the repeal of some laws against the Catholics then enforced in Scotland; and in the riots consequent on the agitation of the question his house was attacked. His literary labours ended with the publication of *An Historical Disquisition Concerning the Knowledge which the Ancients had of India* (1791). R. died on the 11th of June 1793. As a divine he was more at home in the church courts than in the pulpit; his strong common sense and his administrative ability long preserved the power to his party, in spite of the wishes of a large number of ministers, and almost all the laity. Readers of Carlyle's autobiography or Cockburn's memorials know what a delightful position he held in Edinburgh society during one of its most renowned epochs. His histories it is now the fashion to pronounce shallow and unscholarly; his style is somewhat inflexible, and not free from Scotticisms; and his researches have long since been surpassed or corrected and amplified, as by Prescott in regard to America, and Maxwell in regard to Charles V. Still R. will continue to be read for his philosophical analyses of broad national movements, for his power of grouping and contrasting characters, and for the chastened eloquence of his descriptions. As a rule he is to be credited with candid impartiality; he himself says that in writing he always considered himself as giving evidence before a court of justice. Dugald Stewart wrote his Life in 1801; and to the 1822 edition of his works (12 vols. 8vo) Bishop Gleig has prefixed a memoir of the author.

Robespierre, Maximilien-Marie-Isidore, born at Arras, May 6, 1758, obtained through clerical patronage a bursary in the Collège Louis-le-Grand, and having successfully completed his course, settled like R. *pro* as advocate in his native town. The bishop, foreseeing in him an excellent business man, 'happily free from genius,' made him judge of the diocese, but unwillingness to sentence a fellow-creature to death induced him to resign the post. Extant pleadings and prize essays, composed by him in the years 1783-85, are full of allusions to the King, 'that dear and sacred head,' of panegyrics on Rousseau, and railings against Voltaire; but his first distinctly political work, on the state of things in the provinces (1788), combats the preponderance given to nobles and clergy in the elections. In 1789 Artois sent him as one of its sixteen representatives up to the States-General. There and in the Constituent Assembly he made his mark, in spite of the inextinguishable laughter that greeted his sea-green visage, screech-owl tones, and grimaces 'like a cat's,' said Mirabeau, 'that has drunk vinegar'; nay, even Mirabeau confessed, 'This man will make his way: he believes all that he says.' Acknowledged high-priest of the Jacobins (q. v.), and appointed Public Accuser in the new courts of judicature, R. devoted one of eighty speeches addressed to the Constituent Assembly (January-October 1791) to urging the abolition of capital punishment; by another he carried a kind of self-denying ordinance, which let him retire awhile to Arras, and find the place illuminated in his honour. Back in Paris in seven weeks' time, he profited by his exclusion from the Legislative Assembly to strengthen his influence in the Jacobin Club, where, safe from contradiction, he could speak of 'a thousand daggers whetted to take his life,' or 'sacrifice that life to justice, liberty, truth, and boundless love for his fellow-men.' He lay invisible through August 9-10, 1792, when the populace rose, the Tuileries were stormed, the Swiss Guards slain; with Marat provided for the including of personal enemies in the September Massacre; yet 'nearly wept' at the thought that one just man was said to have fallen with the rest. With Danton and Marat he headed the Mountain in the National Convention, cowered in the first two months of its session before Girondist accusations, but by December plucked up courage to argue on the King's trial that here if anywhere right was might. The first six months of 1793 were spent in the annihilation of the Gironde, and Marat's assassination (July 13) left R. almost absolute dictator, with Hébert and Danton, leaders of the Cordeliers, only in his way. Them, too, as Ultras and Atheists, R. and his

creatures of the Committee of Public Safety, St. Just and Couthon, brought to the scaffold (March 1794); and ever glutting the mob with blood, he next must make Convention decree the existence of a Supreme Being, with the consolatory principle of the soul's immortality, on 8th June celebrating the feast of his new worship, a priest and prophet clad in a sky-blue coat. Two days later came Couthon's 'Decree of the 22d Prairial,' extending the Law of Suspects, and giving fresh vigour to arrests; the increase of terror which followed it was all of R.'s secret direction. At length, on 27th July, shouts of 'Tyranny, Dictatorship, Triumvirate,' burst from the Convention, and the meeting ended with the accusation of R., who, on the failure of Henriot's attempted rising, half killed himself, and the guillotine completing his bungling pistol's work, 'went down to hell,' 28th July 1794. His overthrow by men as vile as he was chiefly due to rivalry between the Committees and Convention, to R.'s own disputes with Barrère and Varenne, and to the ridicule roused by his new religion; but that he fell, and with him the Reign of Terror (q. v.), justifies almost any causes of his fall. His virtues of 'amiability,' neatness, and fondness for pets, but throw into stronger relief his vanity, cowardice, cant, and cold-blooded blood-thirstiness; the title of 'Incorruptible' is the one white hair, and consequent defect, in his otherwise utter blackness. A complete edition of R.'s poems, essays, and speeches was published by Laponneraye (2d ed. 3 vols. 1840-42), and his Life has been written by G. H. Lewes (1839), Tissot (1844), and Hamel (4 vols. 1865 *et seq.*). See also Histories of the Revolution by Carlyle, Thiers, Michelet, &c., and D'Héricault's *La Révolution de Thermidor, R. et le Comité de Salut Public en l'An II.* (Par. 1876).

Rob'in Good'fellow, or Hobgob'lin (Fr. *gobelin*, Ger. *kobold*), a domestic fairy of English folklore, answering to the 'Nisse God-Dreng' of Scandinavia, the 'Knecht Ruprecht' of Germany, and the 'Brownie' of Scottish superstition. The offspring of a 'proper young wench' by Oberon, king of the fairies, he ran away from his mother at six years of age, and received from his father the power of turning himself 'to horse, to hog, to dog, to ape,' with the command to 'love those that honest be, and help them in necessity.' According to Book IV. of Reginald Scot's blackletter *Discoverie of Witchcraft* (Lond. 1584), maids were wont to set out a 'boll of milke' for Robin, 'for grinding of malt and mustard, and sweeping the house at midnight, and he would chafe exceedingly if the maid or goodwife of the house, having compassion of his nakednes, laid anie clothes for him besides his messe of white bread and milke, which was his standing fee. For in that case he saith, "What haue we here? Hemton hamten, here will I neuer more tread nor stampen." In the *Midsummer Night's Dream* 'this merry wanderer of the night' appears as a 'shrewd and knavish sprite,' who doth 'jest to Oberon and make him smile,' and bears the appellation of 'Puck.' This *Puck*, or *gouke*, is an old word for 'devil,' the same as the Icelandic *þáki*, Frisian *puk*, and Devonshire *pixy* ('fairy'). See Drayton, *Nymphidia* (282, &c.); Milton, *L'Allegro* (100-114); *The Merry Franks of R. G.*; in Percy's *Reliques* (vol. iii.); and Mr. Aldis Wright's *Preface to a Midsummer Night's Dream* (Clar. Press. Oxf. 1877).

Robinhood' Bay, a creek and village in the N. Riding of Yorkshire, 5 miles S.E. of Whitby. There is here a coastguard station.

Robin'ia, a genus of *Leguminosæ*, as now restricted, consisting of a few N. American trees and shrubs. All the species have pinnate leaves, frequently with spines at their base as stipules; white or rose-coloured pea-like flowers, arranged in racemes springing from the leaf-axils; a short five-toothed calyx; nine united and one free stamens; a slender downy style; and narrow, flat, thin-shelled pods containing several seeds. *R. pseudo-acacia* has already been referred to under Locust Tree (q. v.). This species will grow to the height of 90 feet, but the timber is seldom of sufficient size to serve for shipbuilding, for which it has been recommended. It can be kept in a shrub state by planting close and clipping, and then forms a good hedge plant. The roots have the taste and smell of liquorice, but are poisonous. *R. viscosa*, which has its young branches covered with a viscid substance, and bears rose-coloured flowers, is a smaller tree than the above; and *R. hispida* (Rose acacia), with hispid branches and large deep rose-coloured flowers, in loose racemes, seldom

exceeds 6 or 8 feet in height. Both are natives of the Southern United States, and both are ornamental plants, particularly the last named. The genus *R.* was established in memory of Jean Robin, who was the first in Europe to raise *R. pseud-acacia* from seed. Gerard, in 1599, speaks of him as 'the curious and painful herbarist of Paris.'

Robins, Benjamin, an English mathematician, was born at Bath in 1707. Circumstances denied him the benefits of a good education, but by his own exertions he made sufficient advance in mathematics to be enabled to settle in London as a teacher. Here he continued energetically his own self-culture, and made a considerable reputation by the publication of several mathematical works. In 1742 appeared his great work, the *New Principles of Gunnery*, for which he received the gold medal from the Royal Society. He made a valuable series of experiments, which established the whole theory of projectiles upon a solid basis. He invented the ballistic pendulum for determining the velocity of cannon balls, and suggested a method for calculating the explosive force of a charge. He was the first to appreciate the true value of rifling and the advantages to be derived from the use of elongated shot. In 1749 he was made engineer in general to the East India Company, and went to India the succeeding year. He had hardly finished the plans for the defence of Madras when he died of fever, July 29, 1751. His mathematical works were published collectively after his death by Dr. Wilson (1761); and he is believed to have had a great share in the composition of Anson's *Voyage Round the World* (1740-44).

Robinson, Edward, born at Southington, Connecticut, U.S., 10th April 1794, after graduating at Hamilton College in 1816, and acting as tutor there (1817-18), settled at Clinton till 1821, when he removed to Andover, where he published an edition of eleven books of the *Iliad*, and taught Hebrew under Professor Stuart at the Seminary, helping him also with the second edition of his *Hebrew Grammar* (1823-26). His own translation of Wals' *Clavis Philologica Novi Testamenti* appeared in 1825. During 1826-30 he studied at Halle and Berlin, marrying in 1828 Therese von Jakob. On his return to the United States he was made professor extraordinary at Andover (1830-33), but his health giving way, he removed to Boston, and in 1837 received a professorship in Union Theological Seminary, New York, held by him for the rest of his life. His travels with the Rev. Eli Smith in Palestine in 1838 and 1850 have vastly benefited biblical geography, his greatest work being the *Biblical Researches* (3 vols. 1841, compressed into 2 vols. and a 3d added in 1856). For this book he received the gold medal of the Royal Geographical Society of London in 1842, as well as the degree of D.D. from Halle University, previously conferred upon him by Dartmouth College (1831). Yale College made him LL.D. in 1844. He died 27th January 1864. Besides the works mentioned, R. published *A Dictionary of the Bible for the use of Schools and Young Persons* (1833); *Greek and English Lexicon of the New Testament* (1836; 2d ed. 1847); *Greek Harmony of the Gospels* (1845; 2d ed. 1847); *English Harmony of the Gospels* (1845; 2d ed. 1851), &c. In 1831 he founded the *Biblical Repository*, editing it himself for four years, and in 1843 the *Bibliotheca Sacra*, to which he contributed till 1855. His *Physical Geography of the Holy Land*, edited by his wife in 1864, appeared in 1865. The life of R. has been written by Hitchcock (New York, 1863). — **Thérèse Albertine Louise von Jakob**, wife of the preceding, the daughter of Professor von Jakob, was born at Halle, 26th January 1797. Living with her father in Russia from 1807 to 1816, she learned the Slavic languages, and on her return to Halle began to publish poems. Among her friends were Goethe, the Humboldts, Grimm, Savigny, and Ritter. In 1822 she translated Scott's *Old Mortality* and *Black Dwarf* into German, signing herself 'Ernest Berthold'; in 1824 she published *Psyche, Original Tales*, under the name 'Talvj' (the initials of her name), and in 1825-26 *Volkslieder der Serbeni* (in 2 vols.). After her marriage with Dr. Edward Robinson in 1828, she translated Pickering's essay *On Indian Languages* into German (1834); wrote many essays for her husband's magazine the *Biblical Repository*, among them several on the Slavic languages; and published in Germany, while her husband was in Palestine, her *Characteristics of the Popular Songs of the German Nations*, and

an essay on Ossian (1840). On her return to New York she wrote two small books on American history for use in Germany, several novels which her daughter translated into English, and in 1850 was published her greatest work, *An Historical View of the Language and Literature of the Slavic Nations*. After her husband's death in 1863, she lived at Hamburg, where her son was American consul, and there she died, 13th April 1870. Her *Fifteen Years, a Picture from the Last Century*, was published posthumously.

Robinson, Henry Crabb, F.S.A., born at Bury-St.-Edmund's, Suffolk, May 13, 1775, and after being articled to a lawyer at Colchester and in London, studied at Jena and other German universities (1800-5). Admitted to the 'Weimar circle,' he made the acquaintance of Goethe, Schiller, Wieland, Herder, and Madame de Staël; was *Times* correspondent in Spain during the first two years of the Peninsular War (1808-9); and on returning to London became a regular contributor, being thus brought into contact with many of the leading writers of his day. He was called to the bar (1813), and having acquired a fortune on the Norfolk circuit, retired in 1828 to private life and the society of Wordsworth, Lamb, Coleridge, Landor, and their compeers. A dissenter and a Liberal, he was one of the earliest members of the Athenæum Club, and a founder of University College, London, as also of the Flaxman Gallery. He died in London, February 5, 1867, leaving behind him a delightful Diary, which has been edited by Dr. Sadler (3 vols. Lond. 1869).

Robinson, John, the pastor of the Pilgrim Fathers, was born in 1575, probably in Lincolnshire, entered Cambridge University in 1592, and after holding for some time a benefice near Great Yarmouth, was suspended by the bishop for Puritan leanings in 1602. He drew together an independent congregation at Norwich, and was formally excluded from the Church of England in 1604. In the same year he became pastor of a society of Dissenters at Scrooby, on the borders of Yorkshire and Lincolnshire. Persecution drove R. and many of his flock to Amsterdam, where they were reinforced by other Dissenting exiles. In 1609 the little body settled in Leyden, and there during eleven years their church increased until it had 300 communicants. Through intercourse with Dr. Ames and R. Parker the extreme separatist views of R. were modified, but he continued to condemn the use of the Liturgy and the indiscriminate admission to the sacraments. Entering zealously into the scheme of an American settlement, he promoted the negotiations with the Plymouth company, and dismissed with a farewell sermon the part of his congregation which sailed in the *Speedwell* and *Mayflower*, 22d July 1620. He intended to follow with the rest of the congregation, but before arrangements were completed he died, 1st March 1625. His two sons accompanied the second expedition soon after, and his descendants in America are numerous. R. is the author of various controversial works, which show sound classical scholarship and a luminous dialectic faculty. His complete works, with a memoir by Robert Ashton, and an account of his descendants by W. Allen, appeared in London and Boston in 3 vols. 1851.

Robinson, Sir Hercules George Robert, born in 1824, after studying at Sandhuist, received a commission in the 87th Foot, but retired, and held various Civil Service appointments, and was a member of the Irish Poor-Law Board (1846-53). He was next successively appointed President of Montserrat (1854), Lieutenant-Governor of St. Christopher's (1855), and Governor of Hong-Kong (1859), of Ceylon (1865), and of New South Wales (1872), where his six years' term of office has just expired. Having already been knighted in 1859, he was advanced to the rank of G.C.M.G. in 1875 for his services in connection with the annexation of the Fiji Islands.

Robison, John, a Scotch natural philosopher, was born at Boghall, Stirlingshire, in 1739. After graduating in 1756 at Glasgow University, he became mathematical tutor to the son of Admiral Knowles. In 1762 he was intrusted with the charge of Harrison's chronometer on a voyage to Jamaica, and on his return renewed his studies at Glasgow with the view of entering the Church. Under the influence of James Watt and Dr. Black, however, he turned his attention to physical subjects, and in 1766 succeeded the latter (who had been called to Edinburgh)

as lecturer on chemistry. In 1770 he accompanied Admiral Knowles to Russia as his secretary, and remained in that country till 1773, when he was called to the vacant chair of natural philosophy in Edinburgh University. In 1783 he took a leading part in the organisation of the Royal Society of Edinburgh, of which he was for some time secretary, and to the Transactions of which he contributed several papers. He edited Black's *Lectures on Chemistry* (1803) with illustrative notes; and published a first volume on the *Elements of Mechanical Philosophy* (1822). R. died January 28, 1805.

Rob Roy Macgregor Cam'pbell, the Highland Robin Hood, born about 1665, was nicknamed Roy (Gael. 'red') because of his ruddy complexion, and himself assumed the name of Campbell in consequence of Acts of Parliament abolishing his own. His father, Donald Macgregor of Glengyle, held a lieutenant-colonel's commission from James II., but Rob appears to have followed the humble calling of a small grazier, till, acquiring the Craig Royston and Inversnaid estates, near the head of Loch Lomond, and trusted by the Duke of Montrose with considerable loans, he gradually extended his speculations in the cattle line. These turned out ill; Rob absconded with £1000, obtained on false pretences, in his sporadic; and in June 1712 an advertisement appeared in the *Edinburgh Evening Courant* offering a reward for his apprehension. Montrose's agents, while seizing Craig Royston, insulted Rob's haughty wife, and he himself, having found a protector in the Duke of Argyle, commenced a predatory warfare with his late patron, and also with all upholders of the Union. In the rebellion of 1715 the Earl of Mar sent him to raise a part of the Macgregor clan at Aberdeen, in which city he lodged with a kinsman, Professor Gregory. His lukewarm zeal at Sheriffmuir did not save him from attainer, nor hinder Cadogan from burning his house at Breadalbane, an act which Rob avenged in the succeeding year by relieving the Montrose factor of over £300. For some years longer he continued to levy 'black mail' on the surrounding country, running thereby a hundred risks, captured more than once, but only to escape, writing Montrose a mock-heroic challenge (1719), and to General Wade, the maker of proleptic roads, an offer of his services to George I. Growing at length more peaceable, he fought a final duel with Alister Stewart of Invernahyle, receiving then his first and only wound; turned religious, or at least subscribed to Keith's *History of the Affairs of Church and State in Scotland* (1734), and died in his bed at Balquhider in 1735. He left five sons, the third of whom, James, died an outlaw in Paris, October 1754, while the youngest, Robin, was hanged for abduction at Edinburgh on February 24 of the same year. Concerning Rob Roy himself, his daring, wariness, and generosity to the poor, his strength and ape-like arms, much may be found in Scott's Introduction to his great romance, and something, too, in the *Historical Memoirs of Rob Roy*, by K. Macleay (Edin. 1818).

Roc'amboule, or Span'ish Shall'ot, differs very little in general appearance from garlic (*Allium sativum*), excepting by its larger size in all the parts. The cultivated plant, which has received the name of *A. ophioscorodon*, is a form of *A. scorodoprasum*, a native plant of most parts of Europe, including England and Scotland. R. was formerly grown for the same purposes as garlic, from which it is distinguished by 'the bulbs being smaller, milder in taste, and by the plant producing bulbs on the joints of the stem as well as at the base.'

Roccell'a. See ARCHILL.

Rochambeau, Jean Baptiste Donatien de Vimeur, Comte de, a French marshal, was the son of the governor of Vendôme, and was born there, 1st July 1725. Entering the army in 1742, he took part in the campaigns of Bohemia, Bavaria, and the Rhine. For his services at the siege of Namur he was made a colonel (1747). He also brilliantly distinguished himself at the siege of Maestricht. For his bravery in the expedition to Minorca he received the Cross of St. Louis (1756), and was raised to the rank of brigadier. He took part in the Seven Years' War, became *maréchal-de-camp* and inspector of cavalry in 1761. In 1780 he was sent to America to assist the revolted British colonists with an auxiliary force of 6000 men, and had a great share in the arrangements that forced Lord Cornwallis to capitulate with his whole force at Yorktown, in Virginia, 19th

October 1781. On his return to France he was made governor of Picardy. In 1790 he accepted the command of the army of the North, and in 1791 was made a marshal of France. In 1792 he resigned his command and withdrew to his country estate, narrowly escaped execution by the Terrorists, received the Cross of the Legion of Honour from Napoleon, and died at Thoré, 10th May 1807. See *Mémoires de R.*, by Luce de Lancival (Par. 1809).

Roche'dale, an industrial town of England, Lancashire, situated on both sides and in the pleasant vale of the Roch or Roche, 10 miles N.E. of Manchester by rail. The river is crossed by five bridges, two of which, for passenger traffic, are light iron-work structures. The parish church, dating from the 12th c., stands on an eminence, and is approached by a flight of 122 steps. St. Mary's Chapel-of-ease (1770) was thoroughly remodelled in 1864-66, and among the modern places of worship are St. Alban's, a rich Second Pointed structure (1859), a Methodist Free church in Italian style (1865), a Gothic chapel of the English Presbyterians (1868), All Saints', Hamer, St. Edmund's at Falinge, and St. Peter's (1871); two Wesleyan chapels, two United Methodist Free churches, two Independent chapels, four Baptist chapels, two Catholic chapels, two Unitarian chapels, two Primitive Methodist chapels, a New Connexion chapel, and a 'Friends' Meeting-House. The finest municipal building is the townhall, a Gothic edifice completed in 1867, which is surmounted by a tower and spire, together 240 feet high, and the front of which (220 feet long) faces the river. It contains, besides the municipal chambers, an exchange, borough court, free public library, and a great hall (90 feet by 56). The public baths were opened by the corporation in 1868, and a new post-office was erected in 1875. R. has a grammar-school which dates from 1565, and many benevolent institutions. It is the birthplace and chief centre of the working-men's co-operative movement—the Equitable Pioneers' Co-operative Society, formed in 1844, having (1878) 9700 members, a capital of some £300,000, and yearly sales amounting to £280,000. There are several similar societies in R., and one of these opened the Prince of Wales Theatre in 1867. From an early period R. has been noted for its manufactures. A Flemish colony in Edward III.'s reign introduced the woollen industry, and by the time of Elizabeth R. had attained great prosperity. It is still one of the chief centres of the woollen trade known as *flannel*, but cotton is now manufactured here even more extensively. In 1871, the latter industry employed 5928 men and 7277 women; the former, for woollen cloth, 1909 men and 2699 women, and for worsted goods, 878 hands. The manufacture of engines and machinery employed 788; of spindles, 133; of silk, 400; of iron, 742 hands; while 990 were engaged as coal-miners, and 444 as stone-quarriers. The R. Canal, 33 miles long, completed at a cost of £600,000, unites with the Calder and Ribble Navigation at Halifax, and the Duke of Bridgewater's canal near Manchester, and thus gives the chief seats of trade in Lancashire and Yorkshire connection with the E. and W. seas. Two newspapers are published weekly at R., where also are held important markets for wool, dye-stuffs, and agricultural produce. Pop. (1871) 44,559; (1878) about 65,000. R. returns one member to Parliament. The parliamentary borough was enlarged by the Act 1867, and the municipal borough was made conterminous with it by the R. Improvement Act (1872). The family of Lord Byron were Barons de R., and held the manor and estates for more than two centuries, but these were sold by the poet in 1823. See Robertson's *Guide to R. Past and Present*.

Roche'fort, Henri, otherwise **Le Comte Victor-Henri de Rochefort-Luçay**, a French journalist and politician of the Red Republican school, was born at Paris on the 30th of January 1830, and was the son of a Legitimist Marquis, who was also a noted comic dramatist. After studying medicine for some time, R. took to literature, and, after working for some years as a *chroniqueur* on minor journals, and a contributor to comic papers, such as the *Charivari*, he became one of the principal members of the staff of *L'Événement* and *Le Figaro*. Between 1856 and 1866, he wrote some eighteen or twenty comedies and vaudevilles, generally in collaboration with other dramatists. In 1868 the bitterness of his satirical articles in the *Figaro* upon the Imperial régime caused several prosecutions to be instituted against that paper. On this account he withdrew

from its staff, and began the publication of a weekly pamphlet under the name of *La Lanterne*. More than 80,000 copies were sold on the day of its first publication (1st June 1868), and its circulation as a whole averaged about 120,000 weekly. It was suppressed by the Government after the eleventh number, and prosecutions were instituted against R., who fled to Brussels, where he continued the publication of *La Lanterne*, and, among other things, fought his fourth *duel de journaliste*. In 1869 he returned to Paris, having been elected to the Chamber of Deputies by the First Circumscription of Paris, after being defeated by M. Jules Favre in the Seventh. He now started a journal called *La Marseillaise*, in which he continued his attacks upon the Empire. It was while attempting to arrange a duel between R. and Prince Pierre Bonaparte that M. Victor Noir, a writer in *La Marseillaise*, was shot dead by the Prince in his own salon. Early in 1870 the journal was seized, and a fresh prosecution instituted against R. by the authority of the Chamber. On the 22d of January he was fined 3000 francs and sentenced to six months' imprisonment. The overthrow of the Empire on the 4th of September released him from the Sainte-Pélagie, and he became a member of the Provisional Government, but resigned on the 1st of November. In December he re-established *La Lanterne*, and in February 1871 changed its name to *Le Mot d'Ordre*. Elected in February to the National Assembly, he refused to sit, and by his writings promoted the cause of the Commune. After its fall he was arrested, and sentenced to fifteen years' transportation. He was taken to New Caledonia in 1873, but in March 1874 he made his escape to Newcastle, New South Wales, whence he returned to Europe by way of America. He settled first at Brussels and then at Geneva, in both of which places he continued the publication of *La Lanterne*. In 1876 he became a regular contributor to the newspapers *Les Droits de l'Homme* and *Le Radical*, published in Paris.

Roche'fort-sur-Mer ('the rock fortress by the sea'), a strongly fortified seaport and arsenal of France, department of Charente-Inférieure, situated on the right bank of the Charente, 7 miles from its mouth, and 18 miles S.S.E. of La Rochelle by rail. In its military port the largest vessels float at all times, but the commercial port does not admit close to the quays vessels of more than 800 tons. Tonnyay-Charente, which is 3 miles farther up the river, may be regarded as the proper commercial port of R., for, though vessels coming up the river discharge at R., they almost invariably pass up to Tonnyay to load. The arsenal has immense magazines, cannon-foundries, shipbuilding docks, spacious wharves and repairing basins, and a sail factory with a frontage of 1245 feet. The Marine Hospital, built in 1787, has 1285 beds, and contains a library of 12,000 vols. The finest houses of R. surround the great central square Place d'Armes or Place Colbert, which is adorned with rows of elm-trees. The town has a tribunal of commerce, a school of hydrography, a botanic garden, and a maritime museum. The chief industries are shipbuilding, sail-making, distilling, and the manufacture of vinegar and essences. It has also important commerce in wine, brandy, salt, corn, horses, fish, building timber, and colonial wares. In 1873, in R. and Tonnyay there entered 152 British vessels of 56,156 tons, and cleared 151 of 56,259 tons. Pop. (1872) 21,564.

Roche'foucauld. See LAROCHEFOUCAULD.

Rochelle' (Low. Lat. *Rupella*, 'little rock'), the capital of the French department Charente-Inférieure, 88 miles W.S.W. of Poitiers by rail, is the finest of all the western harbours of France, with roadsteads sheltered by the Ile de Ré and the Ile d'Oleron. Neither its cathedral, an unfinished Grecian structure (1780), nor any of its seven churches, has much beauty, the finest buildings being the Gothic Hôtel-de-Ville (1486-1607), the Palais-de-Justice (1614), the arsenal, and an imposing Bourse. Besides an outer and inner harbour there are two docks, the larger of which, with an area of 7 acres 2066 sq. yards, was deepened and improved in 1874. Plans are now (1878) under consideration for the construction of new floating and dry docks at a cost of £400,000; and the Marans Canal, opened in 1876, is to be ultimately carried through Vauban's fortifications into the harbour. In 1876 the exports included 46,300 gallons of wine, 91,412 gallons of brandy, and 323,000 cubic feet of pit-props; the imports, 86,346 tons of coal, 9368 tons of iron ore, 3215 tons of salt codfish, 4332 tons of wood, and 3079 tons of pitch; while the customs

amounted to £124,957. There entered 273 vessels of 65,125 tons, and cleared 184 of 55,274 tons. The only important manufacture of R. is one of coal bricks, employing 102 hands in 1875; but the neighbouring salt-marshes, covering 5540 acres, engage 4110 more, and the fisheries, ranking twelfth in France, are carried on by 321 boats and over 4500 men. Pop. (1872) 19,506. Founded in the 10th c., R. came to England as part of the dowry of Eleanor of Poitou (1152), was captured by Louis VIII. (1224), but ceded to Edward III. at the Treaty of Bretigny (1360), and finally annexed to France (1372). A Huguenot stronghold, it surrendered to the League after a six months' siege (1573); and in 1628, after an heroic defence of fourteen months, which cost the lives of 15,000 men, Buckingham's expedition bringing no relief, its fall decided the fate of Protestantism in France, and the citizens almost to a man fled abroad, leaving 4000 where sixty years before there had been 72,000 inhabitants.

Rochelle' Salt is a double tartrate of potash and soda ($\text{KNaC}_4\text{H}_4\text{O}_6, 4\text{H}_2\text{O}$), prepared by neutralising cream of tartar with carbonate of soda. It forms beautiful transparent prismatic crystals. It was discovered in 1672 by Seignette, a Rochelle apothecary, whence its name.

Roch'ester (Lat. *Durobriva*, Old Eng. *Hroff-ceaster*, 'the camp on the rock'), a city of Kent, on a bend of the Medway, 31 miles E.N.E. of London by rail, forms almost one continuous town with Chatham (q. v.) on the E. and Strood, across the river, on the W., being joined to the latter by an iron swing bridge (1856), with a centre span of 170 feet. The cathedral, founded by St. Augustine (604) and rebuilt by Bishop Gundulf (1077-1107), is comparatively small, being 306 feet long by 162 feet wide across the large transept, and has a disappointing exterior, with a 'modern Gothic' central tower (1825); the redeeming features are the pure Norman nave, the crypt (one of the few survivals of Gundulf's work), and the fine Decorated doorway of the chapter-house. Its restoration at a cost of £13,000 was completed by the late Sir Gilbert Scott in 1875. Between the cathedral and the river, surrounded by public gardens, stands the 12th c. castle, the finest specimen of a Norman keep in England, 104 feet high. Other buildings are the churches of St. Margaret (mostly rebuilt 1824-40; restored 1872) and St. Nicholas (1624; restored 1863); the Deanery, adjoining the ruins of St. Andrew's Priory, three of whose gateways still remain; the brick townhall (1687), county court-house (1862), St. Bartholomew's Hospital (1863), Borstal Prison (erected in 1874 for 500 convicts), the grammar-school (1542), Williamson's free mathematical school (1701), and Watts' Hospital (1579), described in *The Seven Poor Travellers* of Dickens, who spent the last eleven years of his life at Gadshill (3 miles from R.), the scene of Falstaff's exploits. R. has no special industries of its own, except oyster and other fisheries, many of the inhabitants being employed in the Government works at Chatham. The shipping and trade returns of the two ports are given together, viz., entered (1877) 4340 vessels of 635,630 tons, and cleared 3446 of 355,697 tons; imports (1876) £1,719,445, exports £176,318, and customs £6583. On December 31, 1877, 978 ships of 41,736 tons were registered as belonging to R. and Chatham, besides 105 fishing-boats. R. publishes one weekly newspaper, and sends two members to Parliament. Pop. (1871) 18,352. The seat of the second oldest English bishopric, co-extensive with the kingdom of W. Kent. R. suffered much in the Middle Ages from siege and conflagration, being destroyed by Æthelred, King of Mercia (676), and by the Danes (839), captured by Rufus from his brother's adherents (1087), and three times burnt during the 12th c. James II. embarked here for France after his abdication, 23d December 1688. See Walcott's *Memorials of R.* (Lond. 1866).

Roch'ester, a city of New York, U.S., 7 miles from and 263 feet above Lake Ontario, on Genesee River. Three falls upon this river of 96, 86, and 83 feet high respectively are within the city, and afford immense water power. All lake vessels can ascend to the lowest fall. The main stem of the New York Central Railway crosses the city at the upper fall. The Genesee Valley, the Northern Central, and the R. and State lines also have their termini here. The Erie Canal, on a fine stone aqueduct of 7 arches, and the Genesee Valley Canal, also cross the city. Ready-made clothing is now the largest manufacture, boots and shoes

rank next; there are also 18 flour-mills, 18 breweries, the Leighton Iron Bridge Works, the Stewart Rubber Company, the largest carriage factory in the U.S., 5 tobacco factories, &c. R. is now becoming a great distributing centre for coal, and has also a vast nursery business. A magnificent system of water-works (including a reservoir of 82,000,000 gallons capacity) was recently constructed at a cost of \$3,250,000. It contains a city hall, court-house, free academy, 60 churches, a university with 10 professors and 160 students, a Baptist Theological Seminary with 8 professors and 77 students, 23 public schools with 200 teachers and 10,000 pupils, a public library, an Athenæum, a law library, 2 hospitals (City and St. Mary's), with provision for 500 patients, industrial school, house of refuge, 4 orphan asylums, and other benevolent institutions; a penitentiary, a lunatic asylum, and Mount Hope Cemetery, one of the oldest of its kind in the U.S. There are 3 daily and 4 weekly papers. Pop. (1876) 82,500.

Rochester, John Wilmot, Earl of, was born at Ditchley, Oxfordshire, April 10, 1647. Educated at Burford School, he entered Waltham College, Oxford, when only twelve years old, and at fourteen was made M.A. along with several other young noblemen, by the Earl of Clarendon. In 1661 he set out to travel in France and Italy; in 1665 he served at sea under Sandwich, distinguishing himself for bravery at Bergen; and in the following year he engaged under Sir Edward Spragge, whose message he once carried to another commander in an open boat, amid a storm of shot. But on his return to London, the dissolute court too eagerly welcomed him as a man of fashion and spirit. Charles II. made him Gentleman of the Bedchamber and Ranger of Woodstock Park. He plunged into systematic debauchery of every kind, was by his own expression intoxicated almost uninterruptedly for five years; turned highwayman, chairman, innkeeper, quack doctor, and beggar by turns, in order to pursue the lowest amours; professed the openest infidelity; and, in short, was more corrupt than even the King himself. Occasionally he retired from the court orgies to the study; but even there too often to compose poems the very names of which no modern pen would transcribe. Some of his lyrics, however, are graceful and pure, while his familiar letters to his wife reveal him in the character of a tender-hearted husband. He was altogether a prodigy of vice. The good qualities of a frank and generous nature which he possessed were only passports to the inner circle of the most profligate court in the world; and he must be judged by his time. He had spent his prodigal life at the age of thirty-one; and on his deathbed seems to have made sincere profession of contrition to Dr. Burnet, who by his desire published the well-known *Passages of the Life and Death of John, Earl of R.* The date of R.'s death is July 26, 1680. In 1680 appeared a collection of his poems, with many said to be spurious. His tragedy of *Valentinian* was published in 1685. Several editions of his works have been put forth, the best of which are St. Evremont's (1709) and that printed by Tonson in 1714.

Roche-sur-Yon or Napoléon-Vendée, a town of France, department of Vendée, on the river Yon, 49 miles S. of Nantes by rail. Its principal streets converge to the spacious and central Place Napoléon, in which stands a bronze statue to Napoleon I., the founder of the town. R. manufactures leather, beer, and hats, and has a considerable hardware trade. Pop. (1872) 8841.

Rochet (Low Lat. *rochettus*, from O. II. Ger. *roc*, 'a coat'), a linen garment resembling an albe, only shorter and with close sleeves, formerly worn by priests and acolytes, but at present restricted to bishops and certain privileged canons. It formed part of the episcopal habit prescribed by the first Prayer-book of Edward VI., and the lawn sleeves attached to the Chimere (q. v.) are a later modification of the ancient vestment.

Rock, in Geology, is the general term applied to all materials which make up the earth's crust, from loose friable sand to the most compact limestone or granite.

Rock is a confection of boiled sugar made up in sticks or rolls, and flavoured and coloured like ordinary sweets, from which, indeed, it only differs in form. A spongy, light texture is given to some kinds of R. by repeated drawing out and folding the material while in a plastic semi-viscous condition.

Such R. is opaque; other kinds of R., simply rolled, are transparent and glassy, but by exposure they gradually assume a granular structure.

Rock, Cock of the (*Rupicola aurantia*), an Insessorial bird belonging to the Manakin family (*Piprinae*), and found in S. America and Guinea. It derives its name from the resemblance it bears to the domestic cock. It attains the size of a pigeon, and is of a rich orange colour, the wings being black, and those of the tail brown tipped with yellow. The feathers of the head are erect, and form a double row, and the wing coverts and tail coverts are very conspicuous, forming plumes which closely resemble the tail of the cock. The C. of the R. appears to be solitary in its habits, and to be active at twilight and during the night. The eggs are white, and number two.

Rock'all, a rounded rock rising from the Atlantic Ocean, about 300 miles W. of North Uist, in the Outer Hebrides. It is about 20 feet in height, and is frequented by large flocks of sea-birds. A good deal of fishing is carried on in its neighbourhood.

Rock Alum, or **Roche Alum** (Fr. *Alun de Roche*), a reddish variety of native alum, found near Civita Vecchia in Italy. It is also called *Alun de Rome*, or Roman Alum. Fragments of common alum, coloured with Venetian red, pass in commerce as R. A.

Rock Crystal, the name popularly given to transparent, colourless, nearly pure crystals of quartz or silica. It usually occurs in hexagonal prisms, terminated by six-sided pyramids, and is found in the Alps, Pyrenees, Siberia, Brazil, Ceylon, Saxony, the United Kingdom, and elsewhere. R. C. frequently encloses rutile, asbestos, chlorite, different kinds of fluids, &c. It has many useful and ornamental applications, being the 'white stone' of the lapidary, and the material for the 'pebble' lenses of spectacles. In some localities small brilliant crystals are called 'diamonds,' and are greatly esteemed when made up into personal ornaments. The use of R. C. for instruments of precision—as balance-beams and scale-pans, thermometers, standard weights, &c., has been strongly advocated in Germany of late years, and indeed normal weights of this material have been introduced into the imperial mint for the control of gold coins. In its hardness (7), light specific gravity (2.65), and absolute indifference at ordinary temperatures to atmospheric or chemical changes, R. C. is undoubtedly well adapted for such purposes.

Rock'et is a name primarily applied to *Eruca sativa*, a cruciferous plant of the Mediterranean region, with large white flowers veined with purple, and acrid leaves. In S. Europe the R. is used when young as a salad herb. Various other plants belonging to *Cruciferae* have also (probably from family likeness) received the designation of R., with some prefix. Thus, Bastard R. is *Brassica Erucastrum*; Dame's or Garden R. is *Hesperis matronalis* (see DAME'S VIOLET); London R. is *Sisymbrium Irio* (see HEDGE MUSTARD); Sea R. is *Cakile maritima*; Wall R. is *Diplotaxis tenuifolia*; Winter or Yellow R. is *Barbarea vulgaris* (see CRESS). The name Dyer's R. is applied to *Roseda Luteola*. See WELD.

Rock'et, a pyrotechnic device projected through the air. There are several kinds, as the *sky-R.*, *signal-R.*, *life-saving R.*, and *war-R.*, the principle of construction being the same in all. The sky-R. is formed by filling a stout cartridge cylinder with an inflammable composition such as is used in Pyrotechny (q. v.), and ramming it hard around a 'piercer' or tapering spindle, which leaves a central axial cavity. When the cylinder is nearly filled, a perforated plug of wood or clay is laid in, and over it are placed several pots containing 'decorations,' such as stars, serpents, gold and silver rains, &c. The top is finished off with a conical cap. The conoidal cavity is primed with quick-match, and the finished R. is attached to a stick. On igniting the match rapid combustion takes place in the central cavity, and the liberated gases, meeting with the resistance of the atmosphere, propel the R. upward in a given direction, the stick serving as a guide. When the R. is consumed the terminal 'decorations' explode in mid-air with a pleasing effect. A signal-R. differs little from a sky-R. A life-saving R. is used as a means of carrying a line to a wrecked ship (see

LIFE-SAVING APPARATUS. The use of the R. as an implement of warfare was first rendered practicable by Sir William Congreve in 1803. His R. consists of a sheet-iron case filled with a combustible charge, and the conical head is hollow for the reception of a bursting charge, which is exploded by means of a fuse. The base is closed with a metal disc perforated with five holes, a central one to carry the stick, and four peripheral ones to serve as gas-vents. This R. has been superseded in the British service by Hales' R., which dispenses with a stick. A longitudinal section of the R. and the base disc are here figured.

Hales' War-Rocket.

The metal base has three gas-vents, and each one is partly surrounded by a projecting 'tail-piece' against which the products of combustion play. By this arrangement a rotation of the R. round the axis of its progression is secured, with the additional gains of increased stability and greater accuracy. Four grades of Hales' rockets are used in the British service—namely, 3, 6, 12, and 24 pounders. They are fired from tubes or stands adjusted to a certain elevation and direction.

Rock'fish. See WRASSE.

Rock'ford, a city of Illinois, U.S., on both sides of Rock River, 92 miles by rail W. of Chicago, in an agricultural district of unsurpassed beauty and fertility. It is the seat of R. Female Seminary, and from the rows of trees which adorn it is called the 'Forest City.' There are two furniture factories, one extensive watch manufactory, one woollen and one cotton mill, several flour-mills, five weekly newspapers, and one oatmeal factory. Pop. (1870) 11,049.

Rockhampton, a town in Queensland, on the river Fitzroy (q. v.), 45 miles from its mouth, and 420 miles N.W. of Brisbane. It is well laid out and built, lighted with gas, and amply supplied with water. Vessels of large size can easily come up to the town, the river being as wide and deep as the Thames, with a tidal rise of 14 feet. Above R., however, the navigation is limited to smaller craft, in consequence of a rocky bar across the river. Being the port of a wide extent of country well adapted for rearing stock, and abounding in mineral resources, R. has a large and growing trade. Its principal exports are wool, tallow, preserved meats, gold, and copper. Pop. (1875) 5600.

Rocking Stones, or Loggan Stones, are blocks of stone so exactly balanced that a slight effort is sufficient to displace them so as to set them rocking about from their position of equilibrium, even though their mass may amount to several tons. They are numerous in Cornwall, Derbyshire, Wales, and other places throughout Great Britain and Ireland. They may have resulted from weathering, or perhaps been dropped into position by floating ice during the glacial period.

Rock' Island, a city of Illinois, U.S., on the Mississippi, 180 miles W. of Chicago. It is an important railroad centre, and contains eleven churches, four banks, a public library, and two daily newspapers. It is connected with Davenport, Iowa, by an iron bridge, with passage for trains above and vehicles below. On the island from which the town takes its name stands a national arsenal and armoury. Pop. (1870) 7890.

Rockland, a seaport of Maine, U.S., on Owl's Head Bay, which forms its harbour, about 60 miles N.E. of Portland. It has eight churches, three banks, and four weekly newspapers. Its numerous limekilns produce 1,000,000 casks annually, and it has also extensive shipping. Pop. (1870) 7074.

Rockland Lake, in Rockland county, New York, U.S., 36 miles N. of New York, 1 mile W. of Hudson river, and 160 feet above its surface, is a beautiful sheet of water 4 miles in circumference. Every year some 200,000 tons of ice are cut here for the market by about 1000 men.

Rockling (*Motella*), a genus of *Teleostean* fishes belonging to the *Gadida* or Cod family. The body is compressed near the

tail, and has the first dorsal fin short, whilst the second dorsal and anal fins are long. The mouth has *barbules*. There are several species. The *M. triacirrata* has three barbules; the *M. glauca*, also known as the 'mackerel midge,' attains a length of about 1½ inches.

Rock' Oil. See PETROLEUM.

Rock' River, rising in Fond-du-Lac county, Wisconsin, U.S., traverses Horicon and Koshkonong Lakes, and then flows S. into Illinois, where turning S.W., it reaches the Mississippi 2 miles below Rock Island, after a total fall of 379 feet, and a rather rapid course of 350 miles through a most picturesque and fertile valley. It is navigable only at high water, but affords great water power. Twelve railway lines cross it.

Rock-Rose. See CISTUS.

Rock-Salt (chloride of sodium or common salt) is a widely distributed mineral, being found in cubical crystals and in rock beds or masses in numerous regions throughout the globe. When pure it is colourless and transparent, but most frequently it is tinged red, violet-blue, or green, from the admixture of impurities. R. S. is not confined to any particular geological formation, for it occurs in the New Red Sandstone in the United Kingdom, in Oolitic strata in the Alps, in greensand in Spain, and in Tertiary strata in Galicia. These deposits are believed to have been formed by the evaporation of salt lakes, alternately severed from and joined to the ocean after long lapses of time. The most extensive and productive mines in the world are those of Wieliczka and Bochnia in Galicia. They have been worked for 600 years. The largest British deposits of R. S. are found along the valley of the river Weaver in Cheshire, where two beds attain an aggregate thickness of nearly 200 feet. See SALT.

Rock' Soap, a blackish, soft, greasy mineral, composed of silica, alumina, and water, with smaller proportions of magnesia and sand. It is principally used for artists' crayons, and occurs in igneous rocks in Isle of Skye, Antrim, and other European localities.

Rock'work, in gardening, is an artificial structure of irregular blocks of stone, enclosing earth in which ferns and other plants are grown. R. ought as far as possible to imitate nature, and hence the not uncommon adjuncts of pieces of sculpture, plaster casts, &c., are decidedly out of place. When the base of R. is washed by water, shells and pebbles may be appropriately strewn about.

Rock'y Mountains, the northern portion of the great backbone which runs through the whole length of the American continents, known as the Andes in S. America, the Mexican Cordilleras in Mexico and Central America, and the R. M. in the United States and British America. The mountains in British America and Oregon are known as the *Cascade Ranges*, from the cascades of the Columbia River. Among them is Mount St. Elias (19,500 feet), the highest of the whole northern system. In the United States the R. M. spread to a breadth of 1000 miles, and cover an area of 980,000 sq. miles, constituting the great arid region where agriculture is impossible without irrigation. They are divided into the *Coast Range* of California; the *Basin Ranges*, including the Sierra Nevada, and extending over south-eastern Oregon, southern Idaho, western Utah, Nevada, and north-eastern California (highest points, Mount Whitney, 14,887 feet, and Mount Shasta, 14,442 feet); the *Plateaus*, stretching from southern Wyoming through western Colorado and eastern Utah into New Mexico and Arizona (highest point, Emmon's Peak, Uintah mountains, 13,694 feet); the *Park Ranges*, in southern Wyoming and central Colorado (highest points, Mount Harvard, 14,375 feet, and Gray's Peak, 14,341 feet); and the *Desert Ranges* in southern California, Arizona, and New Mexico. The rocks are principally metamorphic gneiss, porphyry, granite, mica, and talcose slate. The mineral wealth of the R. M. is very great. Gold and silver are found in large quantities in California and Nevada (q. v.), and have more recently been discovered in Wyoming and Dacotah. There are also considerable quantities of mercury, carboniferous limestone, coal, and petroleum. There are evidences of comparatively recent volcanic activity throughout the whole R. M., and geysers and hot springs

are found in many places. The R. M. form the watershed between the rivers flowing into the Pacific, and those flowing into Hudson's Bay and the Gulf of Mexico. Many rivers, however, in the Plateau and Basin districts flow into the central lakes, usually salt, such as Great Salt Lake and Lake Humboldt. See J. C. Fremont, *Rocky Mountains Explorer* (Lond. 1861), Raymond's *Mines of the Rocky Mountains* (New York, 1871), and *United States Geographical and Geological Survey of the Rocky Mountain Region*, J. W. Powell in charge (vol. iii., Washington Government Printing Office, 1877).

Roco'co (from Fr. *rocaille*, 'rock-work'), the name applied to a debased style of architecture prevailing in the 18th c., which was to Italian Classicism what Flamboyant had been to Gothic, or the 'Jesuit' style of the 17th c. to that of the Renaissance. Top-heavy columns, interrupted pediments, an endless multiplication of ornamental details, and studied avoidance of simplicity, with the single redeeming feature of occasional picturesqueness, characterised the R. style, which happily was never adopted by the English except in their furniture.

Rocroi, a small fortified town of France, department of Ardennes, within 2½ miles of the Belgian frontier. It is situated in an extensive plain surrounded by the forest of Ardennes. Pop. (1872) 867. Here the Spaniards were defeated by the French under Condé with a loss of 10,000 men, May 19, 1643.

Bod, known also as a pole or perch, is a measure of length, equalling 5½ yards.

Rodentia (Lat. the 'gnawing animals'), an order of Mammalia, also known as *Gnives*. They are represented by such quadrupeds as hares, rabbits, rats, mice, porcupines, squirrels, jerboas, beavers, &c. Their characters are derived from the absence of canine teeth, and in having only two incisors in the lower jaw. The upper jaw has also two, and very rarely four incisors. The incisors are chisel-shaped, and form the gnawing organs. Their structure is peculiar; in front they are covered with a layer of hard enamel, while behind they consist of the ordinary ivory. The effect of this arrangement is to cause the softer and hinder part of each tooth to wear faster than the hard anterior portion, with the result of keeping a sharp edge on the tooth by the mere act of attrition. These teeth, further, grow from *permanent pulps*, and increase, like the tusks of the elephant, throughout life. The lower jaw of the R. is peculiarly placed, and is so articulated through the longitudinally set condyles, that its antero-posterior movements are free and extensive, and thus are well adapted for gnawing. The molar teeth number about four on each side of each jaw. They have smooth crowns, with the enamel arranged in transverse folds in ridges. The intestine is long, its cæcum being well developed. The brain is smooth, and well-nigh destitute of convolutions. The eyes are placed laterally, and the orbits and temporal fossæ of the skull are continuous. The *placenta* is discoid and deciduate, and the *testes* of R. appear to pass from the abdomen into the scrotum at the breeding season. Despite the fact of the brain being destitute of convolutions, many of the R. possess considerable intelligence; e.g., the rats and beavers.

Roderic, the last king of the West Goths in Spain, was, according to Roderic of Toledo, the son of Theudefred, Duke of Cordova, while the Arab historians make him a commoner raised for his valour to the command of the cavalry of King Witiza. In 709 a revolution deposed Witiza, and placed R. in his stead; but the determined opposition of Eba and Sisebuth, sons of Witiza, and Oppas their uncle, the Archbishop of Toledo, kindled a civil war which was not wholly quenched before the Arab invasion. On the 28th of April 711, 12,000 Berbers, sent under Tarik by Muza, landed at Algesiras, advanced under the guidance of Count Julian, commandant at Ceuta, and repulsed Theudemir, governor of Andalusia. R. hurried forward with an army of from 50,000 to 100,000 men, against whom Tarik could now bring about 25,000 men. They met (July 24) near Xeres de la Frontera, on the Guadalete, where the battle lasted (it is said) eight days. R. had intrusted the wings to the sons of Witiza, who through Julian made traitorous terms with the enemy, that gave him the victory on July 3, 711. R. fell in the battle. His tragic fate, the effect of treason and the weakness of the West Gothic empire, has won the sympathy of many poets, as of Southey, whose poem of *Don Roderick* shows that he had read to advan-

tage the romance of *Don Rodrigo*, written in the 13th c. See Dahn, *Die Politische Geschichte der Westgothen* (2 vols. 1871).

Bodez. See RHODEZ.

Rod'ney, George Brydges, Baron, a famous English admiral, was born at Walton-upon-Thames, 19th February 1718, and quitted Harrow at the age of twelve to enter the navy, where he rose to the command of the Newfoundland station (1748). He was elected member for Saltash (1752), as rear-admiral destroyed the fortifications of Havre in a three days' bombardment (1759), captured Grenada, Martinique, and Santa Lucia (1761), and was rewarded with a baronetcy (1764). Despatched in 1780 to the relief of Gibraltar, then besieged by the French and Spaniards, he achieved his purpose by a victory over the latter off Cape St. Vincent (16th January), then crossing the Atlantic, fell in with and defeated the French fleet near Martinique (17th April), and took the Dutch islands Eustatia, Demerara, and Essequibo, with ships and booty to the value of £3,000,000. On 12th April 1782 R. encountered De Grasse off Dominique, each fleet consisting of more than thirty ships of the line; and the battle, which lasted twelve hours, resulted in a loss to the French of nine vessels, 9000 killed, and a whole train of artillery. Having thus saved Jamaica, and ended the war at a blow, R. returned home to receive the title of Baron R. He lived thenceforward in retirement, dying in London, 23d May 1792. R.'s brilliant victories were chiefly due to his revival of Blake's tactics of breaking the enemy's line. See his *Life*, by General G. B. Mundy (2 vols. Lond. 1830).

Rodos'to (Gr. *Rhaidestos*), a port of European Turkey, vilayet of Adrianople, on the W. shore of the Sea of Marmora, 77 miles W. by S. of Constantinople. Formerly the seat of a Jewish university, it has several mosques, is girt with rich gardens, and supplies Constantinople with fruit, vegetables, and fish. Pop. 25,000.

Rodrig'ues, or **Rodrig'uez**, a small island belonging to Great Britain, situated in the Indian Ocean, 330 miles E. by N. of Mauritius, of which it is a dependency. It has an area of about 60 square miles, with a mountainous surface, and a remarkably healthy climate. The inhabitants, who numbered 1400 in 1876, are engaged in agriculture, rearing cattle for export to Mauritius, and fishing. The imports and exports in 1876 amounted to £3166 and £8271 respectively.

Roe and Roe' buck, the female and male of a species of *Cervida* or Deer (*Cervus capreolus*). The male attains a height of from 2 to 2½ feet at the shoulders. It is of smaller size than the Fallow Deer. The colour is brown, varied with red and grey tints. A white patch occurs at the root of the tail, and the inner surface of the limbs is greyish white. The chin is white, and there is a patch of the same colour on each side of the lip. The R. appears to be monogamous, one male mating with one female. The horns have no snag or branch at the base, and generally have one front antler and two hinder ones. In Scotland the R. is met with in a wild state. The average weight is from 50 to 60 lbs.

Roe, Sir Thomas, was born at Low-Leyton, in Essex, about 1580. After studying at Magdalen College, Oxford, he entered the court of James I., and was knighted in 1604. In 1609 he sailed for 300 miles up the Amazon, and was next sent as envoy to the Great Mogul, Shah Jehan, at whose court in Delhi he resided from 1614 to 1618. He entered the House of Commons as member for Cirencester in 1620, and again in 1640 as member for the University of Oxford. In 1621 he was sent as ambassador to Constantinople, and on his return he presented many Oriental manuscripts, which he had collected, to the Bodleian Library. The Alexandrian MS. of the Greek Bible which he obtained is now in the British Museum. In 1629 R. was successful in negotiating a peace between Poland and Sweden, and it is believed the intervention of Gustavus Adolphus in the Thirty Years' War was due to his advice. In 1641 he was English ambassador at the Diet of Ratisbon, and on his return he was made Chancellor of the Garter and a privy counsellor. He died November 6, 1644. His works are *A True and Faithful Relation of what hath lately happened in Constantinople, concerning the Death of Sultan Osman and the setting up of Mustapha, his uncle* (Lond. 1622); and a *Journal of Voyages to the East Indies, Turkey,*

Egypt, Palestine, and Persia, published first in French (1663), and in English in the same volume with Della Valle's *Travels* (Lond. 1664). In 1730 proposals were made to publish the latter work in 5 vols., but of these only one ever appeared, under the title *The Negotiations of Sir Thomas R. in his Embassy to the Ottoman Porte* (Lond. 1740). The *Journal* has been reprinted by Pinkerton.

Roe'buck, John Arthur, an English politician, was born at Madras in December 1802, his father belonging to a well-known Sheffield family. His boyhood was passed in Canada, whence he came to England in 1824 to study law. R. was called to the bar in 1831, and was returned to Parliament by the city of Bath in 1832. In 1835 he was appointed paid agent in this country by the House of Assembly of Lower Canada. About this time his series of political *Pamphlets for the People* involved him in a duel with Mr. Black, the editor of the *Morning Chronicle*. He lost his seat in Parliament in 1837, but regained it in 1841, to be defeated again in 1847. He distinguished himself as a supporter of free trade, and as a brilliant and daring speaker on many questions, being particularly celebrated for his antagonism to Mr. Disraeli. In 1855 his motion for a committee to inquire into the condition of the army before Sebastopol proved the death-blow of the Aberdeen Ministry, being carried by a majority of 157. R. himself was appointed Chairman of the Committee, which had great influence on the reorganisation of our military system. He defended the Austrian rule in Venetia, and sympathised strongly with the American Confederate party, and with the Danes in the war of 1864. In 1868 he lost his seat at Sheffield owing to his denunciation of trades unions, but was again returned in 1874. Recently (1877-78), he has abandoned the Liberal party on the Eastern question, giving the strongest support to the policy of his old opponent, Lord Beaconsfield. R. is intensely national in his sympathies, and his passionate admiration of his country, though somewhat boastfully expressed, is a sentiment which Englishmen will never despise. He has written a *Plan for the Government of our English Colonies* (1849), and a *History of the Whig Ministry of 1830* (1852).

Roermond, or Remunt (Fr. *Ruremonde*), called formerly **Godsward op de Maas**, a town in the Dutch province of Limburg, at the junction of the Roer and the Maas, 29 miles N.N.W. of Maastricht by rail. It has a fine cathedral of the 13th c., and is the seat of a Catholic bishop. R. manufactures woollens and cottons, paper, and statuary, has important dyeing, and an active transit trade. Pop. (1869) 8816. R. was formerly fortified, and was taken by the Spanish in 1637 and by the French in 1792.

Roe'stone, a variety of Oolite, resembling pea-stone or Pisolite (q. v.).

Roga'tion Days (Lat. *Feria Rogationum*), the three days immediately preceding the Feast of the Ascension, were so named because on them litanies were recited by the clergy and people in procession, a custom of which the modern Beating the Bounds (q. v.) is a relic. Their institution is ascribed to Mamertius, a bishop of Vienne in the 5th c.

Roger I., Count of Sicily, youngest of the twelve sons of Tancred de Hauteville, was born in Normandy about 1031. After serving under his brother, Robert Guiscard (q. v.) against the Greeks and Saracens of Southern Italy, he crossed over to Sicily (1060), and at the head of 300 followers captured Messina. With forces swollen to 700 by the Christian natives, he overthrew 17,000 Moslems in the open field, and, aided by a Pisan fleet, mastered Palermo (1072). The fall of Syracuse in 1088, and of Girgenti and Enna in the two succeeding years, restored the island to the jurisdiction of Rome, and R. received it as a fief from Urban II., with the title of 'Prince of Sicily, hereditary and perpetual Legate of the Holy See.' He died at Mileto in Calabria, July 11, 1101.—**R. II.**, the sole surviving son of the preceding, was born in 1097, and through the death of his cousin William without issue, added to Sicily the dukedom of Apulia (1127). Three years later he obtained from Pope Anacleto II. the title of king, and thus became the founder of the Norman dynasty of the Two Sicilies. The rise, however, of an anti-pope, Innocent II., backed by the Emperor Lothar, forced R. to withdraw to Sicily (1136), but Lothar's death (1137) and

Anacleto's (1138) made Innocent glad to purchase the recognition of his papal claims by himself confirming R. in all his territories. The latter in 1146 invaded the Eastern Empire, but the loss of sixteen galleys in an unsuccessful attack on Constantinople was barely compensated by the plunder of Athens, Thebes, Corinth and Corfu, and the introduction of the silk manufacture to Sicily was the only lasting result of his expedition. In Africa the Norman arms were more successful, and by 1152 R. had subdued the entire northern coast from Tripoli to Bona. He died at Palermo, February 26, 1154, leaving to his son, William I., a kingdom firmly consolidated by justice and toleration. See Gibbon, *Decline and Fall* (chap. lvi.); Büdinger, *Ueber die Normannen und ihre Staatsgründungen*, in Sybel's *Historische Zeitschrift* (vol. iv. 1860); and A. H. Johnson, *The Normans in Europe* (Lond. 1877).

Roger of Wendover, an English chronicler of the 13th c., was a monk of St. Albans, became precentor of the Abbey, and afterwards prior of Belvoir, from which office he was deposed about 1219. He afterwards returned to St. Albans, where he died, it is thought about 1237. His *Flores Historiarum* is a history of the world from its creation in two books, the first coming down to the birth of Christ, and the second to the nineteenth year of Henry III.'s reign. Although not without value for the whole period of English history, partly because he has gathered his materials from sources that have since perished, by far the most important part is that which treats of his own times. Here he is an original author, and writes in a bold, manly, and impartial style. The work has been edited for the English Historical Society by the Rev. H. O. Coxe (Lond. 1841-44), of whose text there is an English translation by Giles in Bohn's *Antiquarian Library*.

Rogers, John, the first of the 'Marian martyrs,' born at Deritend, a suburb of Birmingham, in 1505, was for several years chaplain to the Merchant Adventurers at Antwerp, and pastor of a Dutch congregation at Wittenberg, Saxony, where he turned Protestant. He became acquainted with Tyndale and Coverdale, and using the former's MSS. he prepared a revised edition of the English Bible, based on Coverdale, which he published under the name of Thomas Matthew. Returning to England, he accepted office in the Church, and in 1553 was cited before the Privy Council to answer for a sermon which he had preached at St. Paul's Cross on the Sunday after Queen Mary's entry into London, denouncing Romanism, and urging the people to hold to the Reformation principles. After a long imprisonment, he was tried for heresy before Gardiner, and condemned to be burnt at the stake at Smithfield, a sentence executed on February 4, 1555. His life has been written by Colonel Joseph L. Chester (Lond. 1861).

Rogers, Samuel, an English poet, was born at Newington Green, near London, July 30, 1763. As a boy he was introduced into his father's banking-house in Clement's Lane, but his literary tastes were early developed, and he used to tell of his once mounting the stairs to the door of Dr. Samuel Johnson, but turning coward with the knocker in his hand. His first efforts were a series of essays entitled *The Scribbler*, contained in the *Gentleman's Magazine* for 1781. In 1786 he paid a publisher £30 to print his *Ode to Superstition*, with some other poems; but of these scarce twenty copies were sold in four years. His *Pleasures of Memory* (1792) introduced him to the literary world as an imitator of Goldsmith, and won him many admirers. Soon after his father died, and left him in possession of great wealth, which he used in gratifying the most refined tastes. His famous house in St. James's Place was the repository of exquisite treasures of art and literature, and his hospitality brought within its walls the most famous men of more than half a century. Of his breakfast parties, given in the cool shady morning-room, which Sydney Smith described as 'a place of darkness and gnashing of teeth,' reminiscences are to be found in the journals and memoirs of very many of his friends. His art collection sold for £50,000, after his death. In 1798 appeared his *Epistles to a Friend*, and other poems; in 1812 *The Voyage of Columbus*; in 1814, *Jacqueline*, published in the same volume with Byron's *Lara*; in 1819, *Human Life*—his most vigorous poem, and in 1822, *Italy*. Upon two volumes, containing his *Italy*, and poems illustrated by Turner and Stothard, he afterwards expended, and remuneratively, nearly £15,000. At the death of Wordsworth he was

offered the laurel, but declined it. He died in London, December 18, 1855, aged ninety-three. By his own account he was engaged on the *Pleasures of Memory* for nine years, and on *Italy* for sixteen. But in spite of all his labour and all his taste, he has no place among great poets. His purity of diction does not compensate for his feebleness of imagery, and Hazlitt is scarcely too severe in saying that 'his verses are poetry, chiefly because no particle, line, or syllable of them reads like prose.' R. has some claim to remembrance as a cynical wit, but even his acid *mots* are losing the sharpness of their flavour through the lapse of time. See *Recollections of the Table-Talk of S. R., Esq.*, with a *Memoir of his Life* (1859).

Roggeveeld Mountains, a range in the western portion of Cape Colony, with an average height of 5000 feet. From a distance it resembles an immense wall, and throughout its length of nearly 200 miles there are only one or two available passes.

Rogue Money is, in Scotland, an assessment made annually by the freeholders of each county to pay the expense of apprehending offenders, and of maintaining them in jail, and of prosecuting them.

Rogues and Vagabonds. See BEGGARS, LAWS OF ENGLAND RELATIVE TO.

Rohilkund (*Rohilkhand*), a Division of the N.W. Provinces, British India, bordered N. by the sub-Himalayan tract of Kumaon, W. and S. by the Ganges, and E. by Oude. Area, 11,805 sq. miles; pop. (1872) 5,436,314, of whom 21 per cent. are Mohammedans. This tract is crossed by several tributaries of the Ganges, all flowing S.E., of which the chief is the Ram Gunga. The W. portion will be irrigated by the proposed E. Ganges Canal; the N. portion, which forms part of the *Teraï* (q. v.), is watered by several old indigenous channels, which now (1878) command 52,000 acres. The country is crossed by the main line of the Oude and R. Railway, and tapped by several branches. The chief towns are Bareilly, Shahjehanpore, and Moradabad. The staple crops are rice, other food grains, sugar-cane and cotton. The native state of Rampur (q. v.), the last home of the Rohillas, is entirely surrounded by the Division. R. takes its name from the Rohillas, an Afghan tribe who settled here under Ali Mohamed Khan in the beginning of the 18th c. In 1774, the Nawaub Vizier of Oude obtained from Warren Hastings the loan of a British army, in consideration of the payment of £400,000, in order to enforce payment of the same sum from the Rohillas, who were alleged to have promised to pay it on account of protection from the Mahrattas. The British force was led by Colonel Champion, and the Rohillas stoutly resisted. Puppet-shows are still shown in the town of Bareilly exhibiting white-faced and red-coated soldiers being cut to pieces by Rohilla cavalry. But the British finally won two battles at Futtchgunge, the Rohillas fled to the hills, and the people of Oude gained the plunder and the territory. A Rohilla chief, however, was guaranteed in possession of Rampur, and R. itself was ceded to the British in 1801. In May 1857, the Sepoys at all the cantonments mutinied, and there were no European troops in the Division. The majority of the Christians, civilian and military, were murdered, though some escaped to Agra and Nyni Tal. The Sepoys marched off to Delhi, but the entire population rose in insurrection, and for many months recognised the authority of Khan Behaudur Khan, the dispossessed descendant of an old Rohilla chief. Here he was joined by the Begum of Oude, Prince Feroz of Delhi, and Nana Sahib. Bareilly was not taken and R. cleared until May 1858. The Nawaub of Rampur was loyal throughout.

Rohlf, Gerhard, an African traveller, was born at Vegesack, near Bremen, 14th April 1832. He fought as a volunteer in the Schleswig-Holstein struggle of 1849, subsequently studied medicine at Heidelberg, Göttingen, and Würzburg, and after travelling through Austria, Italy, and Switzerland, went to Algeria (1861), where he served in the foreign legion of the French army, and acquired such a command of Arabic that he subsequently ventured to travel through the interior in a Mohammedan guise. He explored various parts of Morocco and the Sudan, crossed the African continent from the Mediterranean to Lagos, in Guinea, accompanied the English expedi-

tion against Abyssinia (1867), and made two notable journeys through the Libyan desert, the second in 1873, in which he was accompanied by Jordan the astronomer, Zittel the mineralogist, Ascherson the botanist, and Remelé the photographer. R.'s chief works are *Reise durch Marokko* (1868; Eng. ed. by Winwood Reade, 1874), *Im Auftrage des Königs von Preussen mit dem Englischen Expeditionscorps in Abessinien und Land und Volk in Abessinien* (1869); *Von Tripoli nach Alexandrien* (1871); *Land und Volk in Afrika* (1870); *Mein erster Aufenthalt in Marokko* (1873); *Quer durch Afrika, Reise vom Mittelmeer nach dem Tschadsee zum Golf von Guinea* (2 parts, 1874-75); *Drei Monate in der Libyschen Wüste* (1875); *Beiträge zur Entdeckung und Erforschung Afrikas Berichte aus den Jahren 1865-70* (1876); and *Die Bedeutung Tripolitaniens an sich und als Ausgangspunkt für Entdeckungsvorwende* (1877). In 1878 he started from Tripoli, in company with various savants, on an expedition into the Eastern Sahara, which is expected to occupy five years, and the object of which is to explore a *terra incognita* as extensive as Germany and Austria together, and comprising the oasis groups of Wajanga, Kufarah, &c., long known by report but not yet visited by Europeans.

Rohtuck, the chief town of the district of the same name, in the Punjab, British India, 42 miles N.W. of Delhi. There is a manufacture of turbans interwoven with gold and silver thread, and of fine cotton cloth. Pop. (1868) 14,153.—The district of R. has an area of 1811 sq. miles. Pop. (1868) 536,959. It is partly irrigated by the W. Jumna Canal. The crops are millets, wheat, gram, and barley. The breed of cattle is famous. Jhujjur is a considerable town, in a tract which was forfeited after the Mutiny of 1857, when the whole district was for a time lost to the British.

Roland (Lat. *Rutlandus*, *Hrolandus*; Ital. *Rorlando*, *Rolando*, *Orlando*), the famous hero of the medieval epics, is first mentioned in history by Eginhard, who in his *Vita Caroli Magni* describing the rout of a part of the Frankish army at Roncevaux (778), says simply '*Hruodlandus, Britannici limitis prefectus*, fell in the battle with a great number of others.' Of all the *chansons de geste* relating to R., the Girard de Viane is highest in his praise, but it is the noble poetry of what is named *par excellence* the *Chanson de Roland* or *de Roncevaux*, that has given this barely historic character the first place in the popular imagination among the heroes of the Carolingian time. The Song of R. is one of the oldest, and is certainly one of the most remarkable of the heroic poems of medieval France. The earliest MS. of it is in the Bodleian Library, and consists of 3996 verses, the last of which states that it was composed by one Turolf (11th c.). In the Song, R. is a nephew of Charlemagne, a daughter of his sister Bertha by Milon of Anglant, who had wooed the princess unknown to the emperor. At first banished with his mother from the imperial court, R. afterwards gains by his valour and chivalrous spirit the favour of his uncle, and is included among his twelve paladins. Commanding alone, or with other knights, he undertakes great expeditions, even to the remote East, and becomes one of the most dreaded enemies of the infidel. Heathen Spain has been already conquered and forced to sue for peace, when R., leading the rear of Charlemagne's army in the gorges of Roncevals, falls a victim to the treason of his stepfather Ganelon and an army of 20,000 'Saracens.' He and his knights fight with prodigious valour, but in vain. With labour and great pain the wounded R. sounds too late on his ivory horn the signal for Charlemagne to return with the main army, but the giant effort bursts his temples. He still fights bravely, but 'his head pains him full sore.' When he can no longer see, he strikes with his sword Durandal 'ten blows on the brown rock,' that 'God the Father may not be shamed by its remaining among the paynim.' The good steel creaks, but will not break. Soon 'death descends to R.'s heart.' . . . 'Dead is R., God has his soul in heaven: the emperor reaches Roncevals'—to take terrible vengeance on the 'Saracen' king Marsile and on the traitor Ganelon. 'What a picture!' exclaims M. Gerusez, quoting a passage expressing the sympathy of all nature for the death of R. 'Call it, if you will, the infancy of art and language, but have we not here the highest elevation and full maturity of the heroic sentiment?' The tale of R. has been a favourite theme of poets. In France its memory has been kept fresh by the piteous tragi-comedy of Mairêt (1635), the opera of Quinault and Lully (1682), the 'ten-

tative lyrique of Mermet (Opéra, 1864), and the brilliant success of the Vicomte de Bornier's *Fille de R.* (Théâtre Français, 1875). It appeared in Germany in the 12th c. as the *Ruolantes Lied*, by Konrad the priest ('Pfaffe Chunrat'), and was extended in the 13th by the Austrian Stricker. Uhland's ballads have lent the old legend a new charm; in Italian we have Sosteno de Zanobi's *Real di Francia*, Pulci's *Il Morgante Maggiore*, Cielo di Ferrara's *Mambriano*, Boiardo's *Orlando Innamorato*, Folengo's *Orlandino*, Forteguerri's *Ricciardetto*, Ariosto's *Orlando Furioso*; and in English the *Orlando Furioso* is the best tragedy of Robert Greene. See *La Chanson de R. ou de Roncevaux* (Par. 1837; 2d ed. 1869); J. L. Bourdillon, *Le Poème de Roncevaux* (Dijon, 1840); the editions of Genin (Par. 1850), Th. Müller (Gott. 1851 and 1863), Léon Gautier (2 vols. Tours, 1872 and 1875), and Eugen Kolbing (Heilbronn, 1877); *Le Chanson de R.*, translated from the Old French by Adolph d'Avril (Par. 1877); and *Le Chanson de R., Traduction nouvelle, rythmée et assonnée*, by L. Petit de Julleville (Par. 1878).

Roland de la Platière, Jean Marie, was born at Thizy, near Villefranche (Beaujolais), February 18, 1734. At nineteen he left his father's house, and made a peregrination on foot through France. At Rouen a relation of his, Godinot, inspector of manufactures, put him in the way of making a living, and some time afterwards he was nominated inspector of commerce at Amiens. In 1775 he was intrusted by a young friend of his, Sophie Cannel, with a letter to Marie Jeanne Philpon, daughter of an engraver at Paris. The result of this introduction was the marriage of Mlle. Philpon with R., 4th February 1780. He spent four years in Amiens thereafter, and then visited England. On his return from England he was removed in his official capacity to Lyon, and there he composed his *Dictionnaire des Manufactures et des Arts* (4 vols. 1785-90). He and his wife about this time had the principal share in the management of the *Courrier de Lyon*. In February 1791 he went to Paris as commissioner to the Assembly on behalf of the workmen of Lyon, and in December of the same year he fixed himself permanently at Paris. In March 1792 Dumouriez made him Minister of the Interior, and one of his first acts in this position was to subsidise Louvet's journal *La Sentinelle*. When Louis XVI. refused to banish the priests and form a camp of 20,000 men, R. sent him a threatening letter. The king treated the letter with disdain, whereupon R. read it aloud to the Council. The consequence was that Dumouriez had to dismiss him, and he appealed with his letter to the Assembly, which ordered him to print it, and send it to all the eighty-three departments. On August 10, the king's authority having been suspended, R. and the other Girondist ministers resumed their places; but in January 1793 they had again to resign, and on May 31 R. was arrested. He escaped to the neighbourhood of Montmorency, and thence to Rouen. At Rouen the news of his wife's execution caused him to commit suicide, November 15, 1793. Besides the *Dictionnaire* already mentioned, R. wrote *Lettres écrites de Suisse, d'Italie, de Sicile et de Malte* (6 vols. 1776-78), *Mémoire sur l'Éducation des Troupeaux* (1779), *L'Art du Fabricant d'Étoffes en Laine* (1780), *L'Art du Fabricant de Velours de Coton* (1780), *L'Art du Tourbier* (1783), *De l'Influence des Lettres dans les Provinces* (1786), *Recueil d'Idées Patriotiques* (1789), *Le Financier Patriote* (1789), *Compte-rendu à la Convention* (1793).—**Marie Jeanne Philpon, Mme. R.**, wife of the preceding, was born at Paris, March 17, 1754. Her father, an engraver, furthered her education by all the means in his power, and the girl herself, possessed of beauty of person, gave tokens of a mind no less beautiful. In her simple home on the Quai des Orfèvres she became acquainted with many of the greatest works in theology, philosophy, and the sciences. Augustine's Confessions took hold of her mind so strongly that she became for a time an absolute mystic; and Plutarch's *Lives* imbued her with that patriotic devotion which involved her in so many troubles and won her so much glory. At the age of eleven she entered a convent, and there met Sophie Cannel, the friend who introduced her to Roland de Platière, and with whom for eight years she carried on a correspondence. But while yet very young, Mlle. Philpon abandoned the religion she had embraced too impulsively, and during the rest of her life her spirit was that of the Stoics. Her marriage with M. Roland de la Platière took place 4th February 1780. During the following ten years the Rolands led a somewhat unsettled life, now at Paris, now at Amiens, now in England, now at Lyon. When M. Roland

went to Paris, his wife's *salon* quickly became the cabinet of the Girondists. Lovely as she was, it was not her beauty that henceforth influenced these Girondists so powerfully; from her childhood she had accustomed herself to think vigorously and decide firmly; her patriotism was of the purest and intensest kind; her genius for politics far outshone that of her husband; his most important state papers were drawn out by his wife, and indeed she had latterly to deplore that he could neither think nor write except through her. It was Mme. not M. Roland who penned the memorable letter to Louis XVI. which led to the insurrection of the 20th of June. On the fall of her party the Jacobins cast her into prison, and brought the foulest charges against her. She appeared before the Convention on December 7th, and cleared herself triumphantly. When again the Girondist ministers retired in January of 1793, and Roland was arrested, his wife rose from a sick-bed to demand his release. She herself was arrested on June 2, and during her confinement rapidly composed the memoirs afterwards published by Bosc under the title of *Appel à l'impartiale Postérité, par la Citoyenne Roland*. According to a note on the manuscript, 300 pages were written in twenty-two days. Throughout her imprisonment she was heroic; on the last day of her life, she thanked her judges for sending her to her friends, and ran towards her cell as if in haste to die; on her way to the guillotine she spent her time in cheering an old prisoner who wept by her side; and ascending the scaffold she turned to the statue of Liberty and exclaimed, 'O Liberty, what crimes are committed in thy name!' Mme. R. was guillotined 9th November 1793. She forms the noblest contrast to the impure Goddess of Reason whom her executioners worshipped. Her life and character, in combining the best qualities of its spuit, justify the aims of the revolution. See an enlarged edition of the *Appel à Postérité* by Champagneux (Par. 1800); *Lettres autographes de Mme. R., adressées à Bancal des Issarts*, with introduction by Sainte-Beuve (Par. 1835); *La Correspondance de Mme. R. avec les Demoiselles Cannel* (2 vols. Par. 1841); *Mémoires et Correspondance de Mme. R.* (2 vols. Par. 1820; 3d ed. 1855; new ed. by Dauban, 1864); Dauban's *Étude sur Mme. R.* (Par. 1864); and his *Lettres, en partie inédites* (2 vols. Par. 1867).

Roll, a schedule of parchment, on which the pleadings and acts of court were entered and filed with the proper officer, after which they became records of the court. In place of this, copies of the pleadings are now in many cases filed. Rolls of Parliament are the MS. registers of the proceedings of the old Parliaments. The Calveshead was anciently a R. in the two Temples, in which every bench, barrister, and student was taxed yearly, for behoof of the cook and other officers, in consideration of a dinner of calves' heads in Easter term.

Roll, the rapid beating of the drum, producing a continuous sound,

Roll, a cylindrical moulding, very common in Gothic architecture. A *scroll* or *edge-moulding* is the R. with an edge or drip. Sometimes in place of the edge a fillet is added; the R. is then termed a *roll and fillet* or *keel moulding*.

Roll of Arms, in heraldry, a re-Keel and Scroll Mouldings. cord of arms blazoned or illuminated on vellum. The earliest R. of A. in England, is 'Glover's R.', copied (1586) from a list of 1216-72, giving the arms borne by Henry III., the princes of the blood, and the chief barons and knights of that period.

Roll'er (*Coracias garrula*), a species of *Intessorial* birds allied to the Crow. The Common R. occurs in Europe, N. Africa, and Asia. It is rarely found in Britain. Its food consists of insects, worms, &c. The head, neck, and under parts have a beautiful green lustre; the back is purplish brown, and the tail green. The average length is from 10 to 12 inches. The R. lays from five to seven eggs of a white colour. Some ornithologists regard the R. as more correctly placed intermediately between the Swallow and Bee-eater. Other species are the Oriental R. (*Eurystomus Orientalis*), found in India, Java, and Polynesia. The *Eurystomus Pacificus* is an allied form, occur-

ring in Australia, where it is called the 'Dollar Bird,' from the presence of a white coin-shaped patch on the inner aspect of each wing.

Roller, an agricultural implement used for crushing, pressing, and smoothing the surface of land. Ordinarily it consists of a heavy cylinder of wood, cast iron, or stone, mounted on an axle in a suitable frame, and in improved forms of R. the cylinder is composed of two or more sections separately mounted on the axle, so that each section has an independent motion. The clod-crushing R. consists of a series of wheels or rings all separately mounted on a common axle, the periphery of the wheels being deeply notched. By making the slot of the wheel much wider than the axle on which it is mounted, each wheel has a certain amount of play, so that it adapts itself to the inequalities of the ground. Very heavy rollers worked by steam power are now much employed for condensing macadamised roads.

Rolleston, George, M.D., F.R.S., born at Maltby, Yorkshire, July 30, 1829, was educated at the Grammar School of Gainsborough and Sheffield Collegiate School; and, proceeding to Pembroke College, Oxford, was elected fellow (1851). Having studied medicine at St. Bartholomew's, London, and served as assistant-physician in the British Civil Hospital at Smyrna during the Crimean War (1855-56), he became physician to the Ratcliffe Infirmary, Oxford (1857), Linacre Professor of Anatomy and Physiology (1866), and a fellow of Merton (1872). R. is author of an able treatise on *Forms of Animal Life* (1870), besides a *Report on Smyrna* (1856), the Harveian oration for 1873, &c. He has also contributed a treatise on craniology to W. Greenwell's *British Barrows* (Oxf. Clar. Press, 1877).

Rollin, Charles, a French historian, was born at Paris, January 30, 1661. He studied at the College of Plessis, and for three years pursued a course of divinity at the Sorbonne. At the age of twenty-two he became professor in his own college, in 1687 was appointed professor of rhetoric in the College of France, and in 1694 was chosen rector in the University of Paris. He was in 1699 made coadjutant director of the College of Beauvais, and endeavoured to introduce into that almost deserted establishment the system of education afterwards formulated in his *Traité des Études* (4 vols. 1726-28). In 1715 R. lost his post in the College of Beauvais through the intrigues of the Jesuits, because of his alliance with the Port-Royalists. During his retirement he employed himself upon a careful edition of Quintilian (Par. 1715). In 1720 he was again chosen rector of the university, but only to be removed from his post in two months by a *lettre de cachet*. He then engaged upon his famous work, the *Histoire Ancienne*, the first volume of which appeared in 1730, the thirteenth and last in 1738. As regards accuracy, fulness of matter, and correctness of style, this history was pronounced by Voltaire the best compilation in any language; but it is now superseded entirely in every department of ancient history. R. likewise published several volumes of a *Histoire Romaine* (1738), continued by his pupil Crevier. He died September 14, 1741. His *Opuscules* were printed in 1771 (2 vols.). The best edition of his works is that annotated by Guizot in 30 vols. (1821-27).

Rollin, Ledru. See LEDRU-ROLLIN.

Rolling Mills are used in the manufacture of malleable iron, and consist of a train of cylindrical rolls having grooves diminishing in size towards one end, through which the heated metal is passed in succession to improve its quality, and finally to give it the different forms of merchant iron, as bar, rod, sheet, rail, T, angle iron, &c. This valuable substitute for the previous process of hammering was introduced in 1783 by Henry Cort of Gosport. The rolls are usually placed 'two high' in strong 'cheeks' or standards, and a connection is formed by cog-wheels, motion being imparted from a steam-engine. The rolls may be brought closer together by means of lever screws connected through the standards to the upper rolls. Two sets of rolls are employed, called the *roughing* and the *finishing*. In some cases the motion of the rolls can be reversed to obviate lifting the mass of iron from one side to the other. On the Continent 'three-high' rolls are in general use, with which two sets of 'passes' are obtained without reversing the motion. R. M. are also employed for rolling copper, lead, gold, silver and other metals.

Roll, Master of. See MASTER OF THE ROLLS.

Romagna, part of the states formerly governed by the Pope (see PAPAL STATES), comprising the provinces of Bologna, Ravenna, Ferrara, and Forlì.

Romaine, Rev. William, the son of a French Protestant refugee, born at Hartlepool in 1714, was educated at Houghton grammar school and at Oxford. Ordained a priest in 1738, he became a curate near Epsom, and in 1739 published a sermon preached at Oxford University, in which he held, against Warburton, that the Pentateuch teaches the doctrine of a future state. In 1747 appeared the first volume of his edition of Calasio's *Hebrew Concordance and Lexicon*, a work distinguished chiefly by its unwarrantable alterations of the original. Appointed lecturer at St. Botolph's in 1748, and at St. Dunstan's-in-the-West in 1749, he became two years after assistant morning preacher at St. George's. From this place he was dismissed by the rector, Dr. Trebeck, who was displeased by his great success in preaching, and at his fervid and uncompromising Calvinism. For the latter reason, too, his sermon on the *Lord our Righteousness* was the last he was allowed to preach at Oxford. In 1752 he had been appointed professor of astronomy at Gresham College, a position which he soon resigned; his foolish attacks upon the Newtonian philosophy having clearly shown his unfitness. In 1766 he became rector of St. Andrew, Wardrobe, and St. Anne, Blackfriars, an office which he held till his death in 1795, attracting great crowds of every age and rank by his preaching. Among his many works may be mentioned his *Twelve Sermons on Solomon's Song* (1759); *Twelve Discourses upon the Law and the Gospel* (1760); *Life of Faith* (1763); *Walk of Faith* (1771); *Triumph of Faith* (1795). The Rev. Brownley Cadogan collected and published all his works in 8 vols. (1796).

Roman Catholic Church. In explaining the nature and constitution of the R. C. C., it is essential to observe at the outset that, according to Roman Catholic belief, the Church in communion with the see of Rome is identical with the one and only Christian Church established by our Lord, and destined to continue to the end. Hence we cannot understand the idea which animates the Catholic Church at this day apart from the plan with which Christ, according to Roman Catholic theology, instituted his Church at the beginning.

I. *Constitution of the Church.*—Christ, then, as Roman Catholics believe, in founding his church founded an external and visible corporation. He was not content with disseminating his doctrine and leaving it to fructify in the minds of men. He did not consider it sufficient to leave the heirs of his doctrine and his spirit separate to the outward eyes, unknown even to each other, connected only by such bonds of union as are invisible to men and seen by God. On the contrary, he established a church so visible that it might fitly be compared to a city set upon a hill (Matt. v. 13 seq.) an external body to which recourse might easily be had in cases of dispute between Christians (Matt. xviii. 17), a corporation ruled and governed just as all human corporations are, by officers with definite powers and functions (Acts xx. 28, Eph. iv. 11).

It follows clearly, if the above be granted, that the Church does not consist simply and solely of good and pious Christians. Were it so, the Church would be invisible, for it is impossible to discover by any human means who are and who are not faithful disciples of Christ. Because the Church is a visible corporation, she consists of members bound together by external ties, easily recognised by all.

However, there is yet another point which must be noticed before the picture of the Church as a corporation can be complete. All corporations are visible, all have some external token or mark of membership—but more than this is required. There is a certain unity in a mob, but a real body, such as a regiment, a nation, or the like, has a unity which is wanting in the case of a mob, and this because the former are, and the latter is not, under definite and settled government. Hence, the Church consists of two parts, the one composed of officers or governors, the other of subjects placed under their rule.

Up to this point nothing more has been attributed to the Church than can be predicated of any external body constituted by the will of man. And if our Lord had left the plan and the constitution of his Church to the will of man, there would have

been no reason why Christians should not have met together, formed themselves into a body, and elected their own officers. Of course Roman Catholics believe that it was not so in matter of fact. They hold that Christ himself founded the Church after his own pattern. All authority was given to the Church by Christ himself. As, then, visibility and external union form the first essential point in the Roman Catholic idea of the Church, so now the second essential point to be kept clearly in view is that in the Church all authority descends from above. Its rulers do not owe their authority to the ruled, but derive it from Christ, and their commission is neither given them in the first instance by their subjects, nor held afterwards on their sufferance.

Accordingly Christ, after announcing his intention of establishing a kingdom, begins to constitute this kingdom, so to speak, from above. First of all he attached his apostles to his person, and before any church was formed he told them of the power which he intended to place in their hands (Matt. xv. 18, 19, xviii. 15-18). Moreover, among the twelve apostles he chose one, and put the supreme government in his hands. Early in his public life Christ had changed the name of this disciple from Simon to Cephas, *i.e.*, rock, in token, as Christ himself afterwards explained, that Peter's place in the Church was as essential to the Church as that of the foundation-stone in a house. Christ himself held the keys of the house of David, and he promised to place the keys of the kingdom of heaven in Peter's hands. He thus gave him the absolute right of opening the gates for the admission of some, and of closing them for the exclusion of others. He promised that this sentence of admission or exclusion would carry with it all those gifts in the one case or the forfeiture of them in the other which Christ intended to confer upon men by instituting his Church. The other apostles were to share in Peter's powers of binding and loosing. But three prerogatives were reserved for him alone. He only was to be the foundation of the Church; he alone was to hold the keys of Christ's house; he alone was to be the shepherd of the whole flock. Thus Christ, having constituted the apostles as a college under this supreme head, sent them forth with power to receive all nations into the one body of which they were the appointed rulers.

The Church, according to Christ's design, was meant to continue till the end of all things, and as the Church was of divine constitution, the apostles had no power to alter it in its essential features. It was theirs to complete its organisation according to the instructions received from their Master, and then to provide for the transmission of the powers with which they were invested to their successors. In pursuance of this duty laid upon them, St. Peter established his see at Rome, and made the bishops of that city the heirs of his supreme office as pastors and rulers of the whole Church. This is not the place to examine the historical proofs for St. Peter's Roman episcopacy, or for the transmission of his authority to the bishops of Rome as his successors. Suffice it to say that Roman Catholic theologians are agreed in asserting that no fact rests on an historical basis more solid, and that all antiquity recognised the Roman bishop as the successor of the Prince of the Apostles and as the divinely appointed head of the Church.

The apostolic college, as well as St. Peter, who was its chief, must continue in the Church. Therefore the apostles chose other faithful men, such as St. Timothy and St. Titus, made them their successors, and gave them the power in turn to ordain successors in their own place. As the world had been given to the apostles that they might govern it in Christ's name, so it passed and will ever continue under the rule of bishops, who stand in the apostles' place, and receive their jurisdiction from them. The apostles were placed under St. Peter, and exercised their authority in union with and in submission to him, and the bishops of the Catholic Church hold their office in union with and in submission to the bishop of Rome, St. Peter's successor. If each bishop had independent power the unity of the Church would be at an end. But the Church is one body, and for this reason it has in the see of Rome a centre of unity. They and they only are Catholic bishops who are in communion with the chief see, *i.e.*, the see of Rome. They and they only are members of the Church that are subject to him who received from Christ the keys by which the Church, Christ's house, is opened and shut.

Lastly, the bishop is the centre of unity in each diocese, just as the Pope is in the whole Church. The bishop must be united

with the Pope. The subordinate officers, priests, deacons, and the faithful committed to their charge must be subject to the bishop. The bishop has ordinary jurisdiction over the faithful of his diocese. In other words, he is not a mere vicar or delegate, but he exercises authority which comes to him by the standing constitution of the Church. At the same time, the Pope has ordinary jurisdiction not only over the bishops but over each and all of the faithful. He is like a monarch, who may rule mediately through the governors of provinces who have authority given and circumscribed by the statute law, or immediately if he chooses to call cases at once and directly into his own court. He is indeed far from an absolute monarch. He cannot alter the divine constitution of the Church. He cannot do away with the episcopate. He cannot alter the rules of government which Christ has set. But short of this he has absolute power of rule. To him, says the Council of Florence, in the person of blessed Peter, 'Christ has given supreme power of ruling, feeding, and governing the universal Church.' 'He who gathereth not with him,' St. Jerome says, 'scattereth. He who eateth the lamb out of his house is profane.'

Such is the constitution of the R. C. C. Christ made St. Peter and his successors the visible heads of his visible Church. From St. Peter's successor, power descends to the legitimate pastor of a lower grade, and to them all members of the Church owe obedience. The 'Church taught,' as it is called, conveys no power to the Church ruling and teaching. At various periods of history, the people, the lower clergy, or imperial sovereigns have exercised more or less influence in the election of bishops. The mode of the Papal election itself has changed repeatedly: but whatever the power conceded to the laity in nominating the rulers of the Church, these rulers have ever received their orders and their mission not from the laity but from the apostles, and through the apostles from Christ.

II. *The Church as the Organ of Truth.*—This account of the Church's organisation leads us by a natural sequence to describe the purpose for which the organisation was called into being. The first purpose of the Church's organisation in the mind of Roman Catholics is the preservation of revealed truth. We say preservation, for Roman Catholic theologians do not dream that the Church can discover new truths in the supernatural order, or is the recipient of fresh revelations. The deposit of faith—*i.e.*, the religion revealed by Christ—was given in all its completeness to the apostles, and is contained partly in the written Word of God, *i.e.*, in Scripture, partly in his unwritten word, *i.e.*, in apostolical tradition. However, when the Church started there was no Scripture of the New Testament; and again, at the present day the New Testament bears unmistakable marks of the occasional way in which it arose. St. Paul, for instance, does not profess to put his entire doctrine in his epistles. He writes, as occasion serves, for the exigencies of the moment. Besides all this, it is possible for individuals to differ as to the number and names of the books which compose the Bible: and, given the list of these books, private persons notoriously differ as to their sense. If Scripture affords too great room for the divergences of private judgment, still more, perhaps, does this hold true of tradition. Who shall say when a father of the Church is giving an opinion of his own, and when conveying a tradition which has descended from the apostles? Who shall determine the diffusion, the marks of antiquity, the intrinsic character which recommend a custom, a tenet, a tradition, as a legacy received from the apostles of Christ? In short, an authority is needed to declare first what it is which is included in Scripture and tradition, and then to determine the sense of Scripture and tradition.

This authority, Roman Catholics tell us, is the Church. The Scriptures regarded as mere *historical records*, as well as other considerations, lead us to the belief that Christ established a Church as the organ of truth, and that he endowed it with his Holy Spirit. He promised that the gates of hell would never prevail against it, and that he himself would guide it into all truth. It is this Church which fixes the list of canonical books, regarded as *inspired books*; it is this Church which hands down, and owing to divine assistance must needs hand down, the full and perfect revelation intrusted to the apostles; it is this Church which with infallible voice condemns each deviation of the truth as it arises; it is this Church which, though it cannot add to the faith, may still draw inference from the truths once revealed, and put either revealed truths or the inferences in that accurate and explicit shape which is required to bring them into sharp anta-

gonism with the errors of the day. Further, the Church may, in the exercise of her office, define and impose upon the belief of Christians truths given indeed to the apostles originally, but which have been forgotten in certain parts of the Church, or which do not stand out so clearly and unmistakably in Scripture tradition as to be recognised there at once, even before the Church points them out. In all these ways the Church secures unity of faith. To her decisions all, ignorant or learned, wise or simple, all of every nation, must bow in absolute submission. What the Church teaches, they must believe or else forfeit the name of Catholic. The unity thus secured is absolute. Catholics may hold what opinions they like on matters which the Church passes over in silence. Scotists and Thomists, Dominicans and Jesuits, may dispute freely in the schools. But once let the Church decide and then dispute ends, faith begins. No Catholic may distinguish between fundamental and non-essential articles of belief. It is essential to believe all the Church teaches. This unity, too, is internal as well as exterior, grounded, as it is, on a firm and undoubting belief that the Church is guided by the Holy Ghost.

The reader will have gathered from the above that the Church's infallibility embraces for its object-matters truths of faith and morals. No Catholic supposes that the Church is infallible in matters merely historical, or in questions of science and literature as such. But the question arises, how, through what organs does the Church speak? It must be premised that according to Catholic belief it is the office of the bishops to teach—it is the duty of the laity to be taught by them. Again, it may be assumed after what has been said above, that the pastors cannot speak infallibly except in union with the Pope, who is the chief pastor. So Roman Catholics have ever held, and it is a necessary inference from their principles. The Pope is the Church's head by divine ordinance—pastors are only legitimate so far as they are recognised by him. It follows then that the pastors of the Church cannot speak with full authority while the head of the Church is silent.

We proceed to observe that there are three ways in which the Church claims to pronounce infallibility in faith and morals. Sometimes the Pope and the Catholic episcopate in the ordinary exercise of their ministry, or again by decrees solemnly promulgated, impose the obligation of belief upon the faithful. This is known as the teaching of the Church dispensed, and is allowed by all Roman Catholic theologians to be infallible. It was the only way in which faith was given or the Church taught during the three first centuries of her existence. Secondly, the Pope may summon all Catholic bishops to council. In this case the decisions, if confirmed by him, are the judgment of the Church gathered together, and are also confessedly infallible.

Catholics, however, are required to acknowledge a third way in which the Church may pronounce without the possibility of mistake. She may speak through her head alone, and the recent Vatican Council has defined as an article of divine faith that the Pope speaking *ex cathedra* is infallible. The Pope is liable to sin like other men; his infallibility is quite different from impeccability. His knowledge is, of course, human and limited. He has no infallibility in mundane matters. Even in regard to the truths of faith he may go astray, if he speak as an individual or write a theological treatise as a private doctor. But when he, exercising his office as supreme teacher, imposes a belief to be accepted by all the faithful with true interior assent, then, and not till then, the assistance of the Holy Ghost secures him from error.

Every one is aware that it is only within the last few years that Papal infallibility became an article of binding faith. But it must be clearly understood that Roman Catholic theologians strenuously deny that this doctrine is new. Now, the Gallican divines maintained that the Pope in his doctrinal decisions was not absolutely infallible till he had secured the assent, tacit or expressed, of the bishops. Still Gallican with all other Roman Catholics allowed (1) that the Pope is the centre of unity, in such sense that those out of his communion are not to be reckoned Catholics; (2) that the Pope has the chief part in defining doctrine, so that all decisions of general councils need to be confirmed by him; (3) that the Catholic Church is indefectible and infallible. Now, Ultramontanists, *i.e.*, the enormous majority who have always asserted Papal infallibility, urged their Gallican opponents with this difficulty, 'If the Pope can fall into heresy and impose this error as a term of communion, what becomes of

the Church's indefectible infallibility?' The bishops in communion with Rome are no longer Catholic, because on the hypothesis they have fallen away from the Catholic faith. The bishops who preserve the true faith are no longer Catholic, because on the hypothesis they are no longer in communion with Rome. In fact, the theory of Papal infallibility is bound inseparably to the Roman Catholic theory of the Church's infallibility. And the Vatican Council, accepted almost immediately by every single bishop throughout the R. C. C., did but draw an obvious inference from primary Roman Catholic principles. Of course, the advocates of Papal infallibility defended it by express testimonies from Scripture and tradition. But this does not concern us here.

III. *The Church as the Channel of Grace.*—We began by describing the organisation of the R. C. C. We went on to say that through its organisation it professes to teach the one true faith with a voice which cannot err, and to which all nations and all men must listen. Yet, when we say that the Church exists to teach revealed truth, we have omitted one half of her mission. It is the office of the Church to make men holy, no less than to unite them in the one true faith. The two offices are closely connected. The Church teaches a doctrine which is holy by the very fact that it is true and revealed by God. The Church cannot err in expounding and applying all the principles of the natural law, that law which has been written on the hearts and consciences of men. She is no less infallible in expounding God's revealed law, *e.g.*, in explaining the supernatural beatitude for which God made man at the first, the means which God took to redeem and to repair man's fallen nature, and the way in which his creatures can regain his favour. Further, she offers to all men the means of holiness. She professes, through the seven sacraments of the new or Christian law, to open fountains of grace adapted to every want of the human heart, to every necessity, to every state and condition. She gives the most powerful helps and incentives to continual prayer, and, above all, she invites men to the one worship which is worthy of Almighty God, the sacrifice of the body and blood of Christ, commonly called the sacrifice of the Mass. In this tremendous sacrifice, according to Roman Catholic belief, Christ continues in an unbloody manner the sacrifice which he offered on Calvary for our redemption. He still offers himself in sacrifice to the eternal Father through the hands of his earthly priests, for the living and the dead, for each need of the Church or of individual souls. The Mass forms the centre of the Church's spiritual life and worship, and in the communion which forms part of the Mass the Church supplies the greatest means of sanctification.

Lastly, as the Church teaches a holy doctrine, and offers to all the means of holiness, so she is distinguished by the holiness of her children. Of course, Roman Catholics do not deny that there is abundant vice among the children of their Church. They know well Christ's prediction that his Church should contain unholy members. Still they do not hesitate to vindicate the Church's claim to a special sanctity, which distinguishes her utterly from all other bodies. Sanctity, they say, is a note or distinguishing mark of the Church no less than unity. In proof they bid us look at the lives of the canonised saints, men whom God has raised up and continues to raise up in every age of the Church, and to whose sanctity he himself sets his seal by the miracles which he works through their hands while they are still on earth, or for those who invoke their intercession after death. Again, Roman Catholics refer the inquirer to the celibate lives of the priesthood, to the multitudes of religious men and women who have given up home and kindred, property, and, hardest of all, their own will, to follow Christ, under the three vows of poverty, chastity, and entire obedience, to the perfect imitation of Jesus Christ in his essential virtues displayed throughout the Church. Much else might be added. We will only allude, in conclusion, to that vast mass of ascetical and mystical literature which witnesses to the intense earnestness and reality with which lives of prayer are cultivated in the R. C. C., and which, considering its spirit and its character, has nothing at all like it outside the Church.

All that has been said on the Roman Catholic idea of the Church may be summed up in a definition given by the Gallican theologian Tournely, and which is substantially the same as that of the famous Ultramontane controversialist, Cardinal Bellarmine—'The Church is a congregation of men, united by the profession of one and the same Christian faith, and by commu-

nicating in the same sacraments, under the government of lawful pastors, and especially of the Roman Pontiff.'

IV. *Present Aspect of the Church.*—It only remains to sketch very briefly the outward aspect of the Roman Catholic hierarchy at the present hour. At the head stands the Pope, who unites in himself various grades of spiritual authority. He is Bishop of Rome; he is metropolitan or chief bishop of the Roman province; he is Primate of all Italy; Patriarch of the West; and, lastly, Sovereign Pontiff of the universal Church. He is chosen by the cardinals, or rather by such cardinals as are at least deacons, or if not in deacon's orders have obtained power to vote from a preceding pontiff. The election must be made in conclave, with the observance of various solemnities and conditions; and, in order to make the election valid, the votes of two-thirds of the cardinals must fall upon the same candidate. Scrutiny follows scrutiny till the result is obtained. The Pope once elected holds office for life: he may, indeed, like Celestine V., resign of his own free will, but short of this no earthly power can deprive him of his office as head of the Church and vicar of Christ. Around the Pope stands the Sacred College of Cardinals. It consists, when complete, of six cardinal bishops, fifty cardinal priests, and fourteen cardinal deacons. These cardinals are chosen by the Pope, and their dignity is second to his alone. They form a senate round the Pope. It is theirs to assist the Pope in ruling the universal Church, to administer the affairs of the Church on the death of a Pope, and to elect his successor. The cardinals also chiefly compose the Sacred Congregation, which may be roughly described as committees instituted for managing the affairs of the Papal States, or of the Church at large. To the latter class belong the Congregation of the Index, which deals with the prohibition of books; the Congregation of the Council, which settles doubts arising with regard to the decrees of the Council of Trent; the Congregation of Bishops and Regulars, which decides on almost all business which can come before the ecclesiastical court, except those which pertain to faith. The decisions of these congregations possess great authority, and if they are issued after consultation with the Pope, have the force of law.

The cardinals assist the Pope, the legates represent him at a distance. Some of them hold the legatine office as an adjunct of another dignity, and are called *legati nati*. Such was the Archbishop of Canterbury in Catholic times. Others are nuncios, sent by the Pope to temporal princes with power given for a time only. Others, in fine, are legates *a latere*, who are cardinals sent either to provinces or to temporal princes, with the privilege of using the insignia of apostolic dignity, and of superseding, while present themselves, all other legates.

Passing from the Pope, his assessors and his representatives, we come to the patriarchs, bishops who rule over a number of provinces. Constantinople, Alexandria, Antioch, and Jerusalem are still patriarchal sees, although the fact that these countries, once subject to them, are now out of communion with Rome has diminished the importance of the patriarchal dignity. Then follow the primates, who rule over the metropolitans, who rule over provinces, and the bishops who govern single dioceses. These bishops are nominated in various ways settled by canon law, concordats with sovereigns, &c.; but they are always ultimately appointed by the Pope, who nominates them in consistory and issues the mandate for their consecration. Missionary countries are ruled by bishops and priests who have no ordinary jurisdiction, *i.e.*, no power which is attached to their office by the law of the Church in the districts which they govern for the time and at the Pope's will. They are known as vicars or prefects apostolic. In the year 1877 the number of Catholic bishops amounted to 1160.

The orders of Regulars, or religious in the strict sense, are exempt from episcopal jurisdiction. They are subject to their own prelates—abbots, priors, provincials, generals, and the like. These in turn are subject immediately to the Holy See.

A plain and very accurate account of Roman Catholic doctrine will be found in the works of Bishop Hay, especially the *Sincere Christian*, republished by Blackwood, Edinburgh (1871). Those who wish for a deeper and more detailed treatment of the subject, in which the relations of Catholic to Protestant tenets are ably discussed, should consult Möhlers' *Symbolism* (Eng. trans. by Robertson (1847). Dr. Newman examines the Catholic doctrine in its historical aspect in one of his most striking works—*viz.*, the *Development of Christian Doctrine* (3d ed. 1878). For an

account of the origin of the Church and the theology of the New Testament from a Catholic point of view we may turn to Döllinger's *First Age of the Church* (Eng. trans. by Oxenham, 1867). The works of Mr. Allies on *St. Peter*, published by Burns & Oates, may also be recommended to those who would understand the authority claimed by the Holy See, and the grounds on which it rests.

Roman Catholics, Laws Regarding. See ACT OF TOLERATION. In the United Kingdom, a Roman Catholic priest is not eligible as a member of the House of Commons. The performance of religious service according to the rites of the Church of Rome by any one is legal proof of his coming within the scope of the prohibition. A Roman Catholic may now hold any office in the United Kingdom, except those of sovereign or regent, of Lord Chancellor, or Keeper of the Great Seal, of Lord-Lieutenant of Ireland, or of Lord High Commissioner to the General Assembly of the Church of Scotland.

Romance, or **Romanza**, a little song with a love story, or a melody imitative thereof. The word is derived from the songs of the troubadours having been sung in the R. languages.

Romance Languages, the collective designation of the six great modifications of the *Lingua Romana Rustica*, or provincial Latin of the Empire—Italian, Provençal, French, Spanish, Portuguese and Wallachian. Each of these being treated under its special heading (Wallachian under RUMANIA), it will here be enough to refer to the works of Diez (q. v.) and to the valuable articles contained in *Romania, Recueil trimestriel consacré à l'étude des Langues et des Littératures Romanes* (Par. 1872-78).

Roman Cement is a term commonly applied to any hydraulic cement prepared from natural cement stones. Parker's R. C., made from the *septaria* of the London clay found at the Isle of Sheppey, was introduced in 1796. Since then similar argillaceous nodules have been found in many other localities in Great Britain, and these constitute the basis of a score of other Roman cements now before the public. See MORTARS.

Roman Empire, The Holy, began on Christmas Day, 800, when Karl the Great was crowned by Leo III. in St. Peter's Basilica at Rome, and ended 1006 years afterwards, when Franz II., Karl's sixty-fourth successor, resigned the imperial dignity, 6th August 1806. The epithet 'Holy' was added by Friedrich Barbarossa, occurring first in his *Privilege of Austria* (1156), and was adopted specially as a protest against Hildebrand's assumptions of exclusive priestly sanctity and absolute priestly jurisdiction, but generally to express the fact that the H. R. E. was simply a temporal aspect of the Holy Catholic Church. For pope and emperor held co-extensive sway, reaching to the earth's utmost limits, and Caesar's dignity was paramount, in theory at least, over every king, duke, or commonwealth of Christendom. Thus Edward III.'s refusal to kiss the foot of Ludwig the Bavarian attests those claims which Charles the Bold acknowledged by seeking leave of Friedrich III. to elevate his duchy into a kingdom. That the imperial office became annexed to German sovereignty, to Karoling, Saxon, Hohenstaufen, or Hapsburg dynasties, was no more an essential feature of the imperial, than that all modern popes have been Italians is of the papal theory. It was as 'Romans,' as heirs to Julius and Justinian, that emperors asserted their right to universal arbitration, which right was widely recognised throughout the Middle Ages, with mingled good and ill results, nor till it had come to be a sham did the H. R. E. pass for ever away. See EMPEROR, GERMANY, and Bryce's *Holy Roman Empire* (3d ed. Lond. 1871).

Romanesque Style, The, so far from being a mere corruption of classic Roman architecture, was, says Mr. Freeman, 'a more perfect carrying out of ideas which classical Rome attempted only imperfectly.' Falling back on the earlier round-arched construction exemplified in the pre-classical emporium by the Tiber in aqueducts and military towers, it abandoned the Grecian architecture of the entablature for a design where columnar capitals immediately support the arches of the arcades, as seen in Diocletian's palace at Spalato (circa 304 A.D.). To the 5th and 6th c. basilicas of Ravenna, marking the gradual development of Romanesque, succeeded the buildings of Lucca,

and to these again the crowning glory of the cathedral of Pisa. The invention of bells had given rise to the erection of lofty campaniles, and the Italian type of church stood perfect, with its triumphal arch, long-drawn arcades, and apse within, while without the whole effect depended on the slender tower. The Norman Style (q. v.) grew from a fusion of Byzantine with Romanesque, but England, down to the Conquest, or at least to Edward the Confessor's reign, retained the Primitive Romanesque which Augustine brought with him direct from Italy. To this style belong the scanty specimens spared us by Norman builders of so-called 'Anglo-Saxon' architecture—the crypts of Ripon and Hexham, the nave and tower of Deerhurst, and the small but highly-finished church of Bradford-on-Avon,—besides the original minsters of Sherborne and Malmesbury, Æthelwold's church at Winchester, Oswald's at Worcester, with others long perished utterly. The leading features of all these buildings connect them with the earlier Italian rather than the later Norman style, the 'long-and-short' work, namely, resembling the masonry of the Verona amphitheatre; the small and narrow windows, splayed within and without; the columns, rude, but still recalling classical proportions; and above all the tall, unbuttressed towers, e.g., of Earls Barton and St. Benet's at Cambridge, whose single ornament consists in hard, square strips. In Italy, in the 13th c., the native Romanesque was superseded by an imitation of the architecture of the N.; along the Rhine Primitive Romanesque lived on into the 12th c. and was the direct predecessor of Gothic, but in Northern France it had already a hundred years before made way for the Transition style, distinguished by vaulting and domical construction, which, as Norman, was introduced into England in the 11th c. See vol. v. of Freeman's *Norman Conquest* (Oxf. 1876).

Roman Law. The law of ancient R. was based on the constitutions of its kings, on the *twelve tables* of the laws of the *Decemviri* (q. v.), on the statutes enacted by the senate and people, on the edicts of the praetors, and on the *Responsa Prudentium*, that is, the opinions of learned lawyers; and, latterly, on imperial decrees. Due weight was given by the Roman law to customary or unwritten law (see CUSTOM; COMMON LAW). The material constructed on the above bases was first reduced into a *Code* (q. v.) by order of the Emperor Theodosius (A.D. 438). It continued for several centuries to be the only legal compilation recognised in the Western Empire. The operation of Justinian's embodiment of R. L., compiled by Tribonian about A.D. 529, was limited to the Eastern Empire. It consists, 1st, of the *Institutes*; 2d, of the *Digest* or *Pandects* (q. v.); 3d, of a new *Code*, or collection of imperial constitutions; 4th, of the *Novellae* (q. v.). These form the *Corpus Juris Civilis*, as published about the time of Justinian. The systematic manner in which the Romans completed their conquests, combined with the general wisdom of the Roman law, have caused it to be adopted as the foundation of nearly every system of jurisprudence in Europe. It has had less influence on English jurisprudence than on that of Continental Europe generally, and of Scotland. The term *Civil Law* is sometimes specially applied to Roman law. See Taylor's *Introduction to the study of Civil Law*, *Elements of Civil Law*; Gibbon's *Decline and Fall*.

Roma'nof, a famous old Russian Boyar family, which ascended the imperial throne of Russia in 1613. Its founder Andrei, surnamed Kobyla ('the mare'), is said to have come in 1341 from Prussia to Moscow, where he entered the service of Simeon the Proud. His son Feodor, called Koshka ('the cat') had, five sons, from which are descended the families of R., Sychovo-Kobylin, Kalytsheff, and Sheremetieff. Feodor's grandson Zachorji Ivanovitch Koshkin, left two sons, Jakoff, a general whose descendants call themselves Zacharjin-Jakovleff, and Jurji, who by his son Roman became founder of the family of Zacharjin-Jurieff. Roman's daughter Anastasia was in 1547 married to the Czar Ivan II., and her brother Nikita to Eudokia, Princess of Susdal, descended from a brother of Alexander Nevski. Of this family Michael Feodorovitch R., son of Philaret or Feodor, the Metropolitan of Rostov and Patriarch of Moscow, was chosen Czar to put an end to anarchy. On his death in 1645 he was succeeded by his son Alexei, who died in 1676, leaving two sons, Feodor III. and Ivan III., and a daughter Sophia, by his first marriage; and by his second Peter the Great, the regenerator and first Emperor of Russia. By his first marriage Peter had a son Alexei (died 1718), whose

son Peter II. was Emperor, 1727-30, and by his second the daughters Anna and Elizabeth (Empress 1741-62). With the latter the imperial house of R. died out, and the house of Holstein-Gottorp ascended the throne with her sister Anna's son, Peter III.; yet this house is also often called R., by reason of its female descent therefrom. See Campenhausen, *Genealogisch-Chronologische Geschichte des Hauses R.* (Leips. 1805); Fredeburg, *Rossijski Zarstvenny Dom Romanovych* (Petersb. 1853 et seq.).

Roman Religion. The close connection of the religions of the Greeks and Romans in their earliest form is proved by the identity of the names of their chief gods, *Jupiter* (*Diævis*) and *Zeus pater*, *Vesta* and *Hestia*, *Juno* and *Dione*, *Janus* and *Zen*, *Mars* and *Arës*. But while the character and circumstances of the Hellenes led them more and more to the complete anthropomorphism that Attic sculpture perfected and developed, as the dominant elements in Greek mythology, personality, freedom, and the richest diversity, the Roman theology is throughout characterised by the abstract idea, by necessity, and by the severest order and monotony. In prayer the Greek looked to heaven, the Roman veiled his face. The powers of nature were to the Roman only personified ideas, and the nebulous character of his gods is seen in the formulæ, '*Sive Deo, sive Dea*,' '*Sive Mas, sive Femina*,' '*Sive quo alio nomine te appellari volueris*.' While the remains of early Roman mythology are therefore scarce, every social condition, every operation of husbandry, had its representative in the spirit-world. This Mommsen traces to 'the profound sense of the existence of the general in the particular,' and the devotion and self-sacrifice of the individual to the whole, which he regards as 'the basis of the political union and universal dominion of the Roman Empire.' The difference between the Greek and the R. R. corresponds exactly to that between the Hindu and Persian religions, to the latter of which the Roman affords a complete parallel. As in Parsism, the ethical rises above the mythological, while the number of *genii* is unlimited. Chief of these are the roughly distinguished *Lares*, *Penates*, *Manes*, *Larvæ*, and *Lemures*. The *Dii* or *Divi* include all personal and intelligent beings of sky, earth, or under-world that rule nature by their will (as *numina*). A few evil deities like Vediovis, Robigo (god of corn-rust), Consus (of the hidden germs), and Carmentis (of incantation), are worshipped; but the good gods like Faunus and Saturnus, Vulcanus and Vesta, and especially the three greatest, Jupiter, Janus, and Mars, have absolute power over men and morals, as well as over nature. Other deities named in the festival calendar are Tellus (the nourishing earth), Ceres (goddess of growth), Pales (of fruitful flocks), Ops (of the harvest), Terminus (the boundary-stone), Neptunus, Mater Matuta (the morning goddess), Liber and Libera (the deliverers). From the fusion of the Sabines with the Roman shepherds, when R. became more of an Italian centre, the three chief gods were raised still higher above the others, Jupiter as the good father, pure and holy, Mars as the protector and god of war, and Janus as the god of summer, the opener of the day and of all life. To the practical Roman the *cultus* was everything, and true religion was piety according to the letter of the law. The root of Roman religion was the belief that the gods might be used to gain practical advantages. All had equal access to the deity. The priest was in no sense a mediator, but was a skilled ritualist who could perform with exactness the complicated ceremonies of the sacrifices. Of the twelve *flamines* ('fire-kindlers'), the three principal (*maiores*) were the *Flamen Dialis* (of Jupiter) and the two priests of Mars (*Flamines Martialis et Quirinalis*), the heads of the two Sabian Colleges. The Augurs and the College of the Chief Pontifex (q. v.) served no special duty. From the foundation of the temple of Jupiter on the Capitol by the Tarquins and Servius Tullius to the decline of pre-Christian Rome, the R. R. held an even course. Splendid games and a magnificent ritual were associated with this citadel of 'mightiest and greatest Jove' (Jupiter O.M.—formula for *Optimus Maximus*), which should be the head of the whole world, as he was the divine personification of conquering Rome, before which all the nations should tremble and bow down. However favourable the influence of this religion on political life, it supplied nothing to the spiritual wants of the people, who turned in time to the rites of the East. The Massilian Artemis was worshipped on the Aventine, and the books of the Cumæan Sibyl were removed to Rome. To these first traces of Hellenic influence were quickly added the

rites of Dēmētēr, Persephonē, and Dionýsos (who were identified with Ceres, Libera, and Liber), and of Apollo, Æsculapius, Castor and Pollux. Aphrodītē was identified with Venus, goddess of gardens, and ere long the popular worship gathered round the Erycinian Venus, the mother of Æneas. The Hellenic deities were followed by the Asiatic, as 'the Great Mother,' whose image, an unhewn stone, was brought at state expense from Pessinūs to Rome. Still, it was chiefly the corrupt and sensual elements of these religions that were received by the Romans. Among the upper classes, philosophy replaced the state religion with incredulity, which was quickly overgrown with the rankest superstition. The policy of Augustus might restore the forms of the national worship, it could not rekindle their old life. The age of the empire is marked by the development of the universalism that found Jupiter in the supreme gods of every nation, and by the deification of the Emperor, his incarnation upon earth. In the composite Græco-Roman civilisation, the highest of the ancient world, Christianity—the last and most precious gift of the East to the West—found a favourable soil. The first form in which Christianity became an established religion was Roman, and the Roman Catholic Church is but the Roman world-empire ennobled by the spirit of the gospel. See Hartung, *Die Religion der Römer* (2 vols. Erlangen 1836); Heffer, *Die Religion der Griechen und Römer* (4 vols. Brandenb. 1845); Schwegler, *Römische Geschichte im Zeitalter der Könige* (Tub. 1853); Preuner, *Hestia-Vesta* (Tub. 1864); Preller, *Römische Mythologie* (2d ed. 1865); Mommsen, *Römische Geschichte* (6th ed. Berl. 1874; Eng. trans. 1867); Roscher, *Studien zur Vergleichung der Griechen und Römer* (2 vols. Leip. 1873-75); and Tiele, *Geschiedenis van der godsdienst tot aan de heerschappij der wereldgodsdiensten* (Leiden, 1877; Eng. trans. 1877).

Romans, a town in the French department of Drôme, on the right bank of the Isère, 12 miles N.E. of Valence by rail. It is connected with Péage, on the opposite side of the river, by a bridge built in the 9th c. by the monks who had the right of toll (*péage*), and owes its origin to the abbey founded in 837 by St. Bernard, Bishop of Vienne. It manufactures silks and woollens and trades in wine, oil, and skins. Pop. (1872) 9893.

Romans, Epistle to the, was written by St. Paul from Achaia, probably Corinth (*cf.* xv. 25, 26). The circumstances indicate that this was his last stay in Achaia (Acts xx. 3); so that the Epistle would be written about 58. It is generally assumed that there was a Christian Church at Rome, composed, according to different critics, in different proportions of Jewish and Gentile Christians. The assumption is really no better founded than the tradition that Peter was the founder and first bishop of that Church. The community in Rome to whom Paul wrote were Hellenistic Jews, very similar to those in Alexandria, with whom they had much intercourse. See PAUL.

The great theme of the Epistle is the Gospel doctrine of justification by faith. In showing that this is the only possible means of salvation for all men, Jews as well as Gentiles (i. 18-ii. 29), the apostle has to combat the prejudices of the former regarding their national privileges (iii.-v., ix.-xi.), as well as Antinomianism generally (vi., vii). The latter part of the Epistle (xii.-xvi.) is practical. By many critics the doxology, xvi. 25-27, and by some the whole of xvi., is regarded as spurious. See Davidson's *Introd. to the New Test.* (Lond. 1868), Jowett's *Commentary* (1859), Meyer's *Commentary* (1859).

Roman'ticism, the reaction from classical to medieval forms, originated in the Gottsched and Bodmer controversy (1740) on the respective merits of French (Voltairean) and English (Miltonic) poetry. From *Paradise Lost* Bodmer, with Haller, Wieland, and Klopstock, turned to the old Teutonic literature; and his editions of the Minnesingers, faulty though they were, roused in the German mind an admiration of bygone German poetry, akin to that awakened for our ballads by Percy's *Reliques*. The movement, traceable through Lessing's, Goethe's, and Schiller's writings, acquired fresh force and first received its name when towards the close of the last and the beginning of the present century 'nationality' became the general watchword, and Tieck, the brothers Schlegel, and Novalis dreamed of a school of poetry where 'all the picturesque life of the Middle Ages of Germany should be renewed.' These, the founders of R. proper (so named because the Minnesingers had drunk their inspiration from Romance sources), were followed by Arnim, Fouqué, Uhland,

Körner, and other worshippers at medieval shrines. In England, Scott worked a similar movement mainly by his own unaided genius; to France R. was communicated through Madame de Staël, but there became less an assertion of new laws than a denial of all existing traditions. The members of the Cénacle, or Romantic Pleiad—Victor Hugo, Sainte-Beuve, Gautier, Deschamps, &c.—renounced the classicism of Racine and Corneille without exclusively adopting medieval themes or models; and French R. is defined by Hugo himself as 'liberalism in literature.' Everywhere the political and literary influences of R. have well-nigh passed away; its action on art and on religion has been more permanent, as shown in England by the Gothic revival, Pre-Raphaelism, and Tractarianism, which last Newman ascribes to Scott's romances. See Haym's *Romantische Schule* (1870); and Gautier's *Histoire de Romantisme* (1872).

Rome, the metropolis of the Roman republic and empire, the ancient centre of Western civilisation, the Eternal City of the Popes, and the capital of the modern kingdom of Italy. It lies in an undulating volcanic plain, now called the Campagna (q. v.), on both banks of the 'tawny Tiber,' 14 miles from its mouth. R. is girt by an old brick wall 14 miles long and 55 feet high on the outside, but by far the greater part of the enclosed space is occupied by ruins, gardens, and vineyards. The city is divided into two unequal portions by the river, which has here an average breadth of 65 yards and a depth of 20 feet. The Tiber describes three curves in flowing through the city, and is spanned by five bridges, including a new suspension-bridge. Ancient R. is situated on the left bank, partly in the plain which stretches along the river, the ancient Campus Martius, and partly on the far-famed seven hills. Further N. lies the closely-packed and tortuous city of the Middle Ages, now the abode of the poorer classes, and between this and the Quirinal and Viminal Hills on the E. is modern R., the fashionable strangers' quarter, and the chief centre of business. The much smaller portion of R. on the right bank of the Tiber is divided into two parts: to the N. the Borgo, surrounding the Vatican and St. Peter's, and encircled by a wall built by Leo IV. in 851; and to the S. Trastevere, lying along the river, and on the slopes of the ancient Mons Janiculus.

Once densely peopled, ancient R. is now almost tenantless, but contains the grandest monuments of antiquity. Five of the hills, joined together by a ridge, form a semicircle bounding the Campus Martius. Furthest N., the Monte Pincio (175 feet) is now laid out in public pleasure-grounds, and was the *Collis hortorum*, on which were situated the famous gardens of Lucullus. The 'hill of gardens' was not included among the seven hills of the city, these being the Quirinal, Viminal, Esquiline (the highest, 246 feet), Cælian, Aventine, Palatine, and Capitoline. Between the Palatine and Capitoline, in the S., is situated the ancient Forum (q. v.). On the summit of the Capitoline are the church of Santa Maria in Araceli, which is mentioned in the 9th c., and occupies the site of the temple of Juno Moneta; the Piazza del Campidoglio, designed by Michael Angelo, and in which is placed a bronze equestrian statue of Marcus Aurelius; the Palazzo del Senatore, re-erected by Boniface IX. in 1389 on the site of the ancient Tabularium; and the Palazzo del Conservatori and Capitoline Museum (founded by Innocent X.), containing the precious relics of recent excavations. The site even of the great Temple of Jupiter (see CAPITOL) is matter of dispute, and the only relic of the ancient buildings which covered the mount are the imposing ruins of the Tabularium. Popular assemblies were held in the *Area Capitolina*, and here, on the suppression of the revolt of Tiberius Gracchus (B.C. 133), the blood of the citizens flowed for the first time in civil war. On the S. height of the Capitol, the Monte Caprino, are the so-called *Casa Tarpeia*, with the Protestant hospital and the German Archaeological Institute, erected by Laspeyres in 1874-76. The Palatine, the germ of the ancient city, and subsequently the site of the palaces of the emperors, is now covered mainly by two recently dissolved religious houses, S. Bonaventura and the Villa Milla, and by the old Farnese gardens. Since the purchase of the Farnese gardens by the Italian Government in 1870, the extensive excavations carried on here have been entrusted to the sole management of M. Rosa. Between the Palatine and the Aventine lay the Circus Maximus (q. v.). Designed for the drainage of the Forum Boarium, or cattle-market, lying between the Palatine and the

Tiber, the Cloaca Maxima (q. v.), the earliest known application of the arch principle in R., has defied the vicissitudes of 2000 years. The Pantheon (q. v.), near the centre of the Campus Martius, is the only ancient edifice of R., the walls and vaulting of which are in a perfect state. To the S.E. of the Aventine were the Baths of Caracalla (see BATHS), and in the depression between the Palatine, Esquiline, and Cælius stands the Coliseum (q. v.), the interior arrangement of which has been revealed most minutely by the excavations of 1874. Among the grandest memorials of R. are the triumphal arches (see ARCH), the most elaborate and best-preserved of which are those of Constantine, Septimius Severus, and Titus. The principal street of ancient R. was the Via Sacra, part of the basal pavement of which is still visible; the Via Appia was the great road leading S. from the city; the Via Lata that leading N. At the N.E. base of Cælius is the Basilica of the Lateran (q. v.). Beyond the S. slope of the Esquiline the ruins of ancient R. become scarcer. During recent years archaeological research has been carried on with great enterprise. At three different periods R. has been defended by three distinct walls—that encircling the Palatine, that of Servius Tullius, enclosing the Seven Hills, and that of Aurelian still standing. Four fragments of the Palatine wall have been discovered, while that of Servius Tullius may now be traced at forty-two different points. Some vestiges of the citadel or *arx* on the N.E. summit of the Capitoline were laid bare in 1875. There are now no fewer than thirty temples, and of those recently discovered the chief are the temples of the Flavians, with a colossal head of Titus (discovered 1872), of the Fortuna Primigenia, with many inscriptions (1873), of Julius Cæsar, with many fragments of the *Fasti Consulares et Triumphales* (1873), of Honour and Virtue (1873), and of Jupiter Capitolinus (1865–76). In the period of her splendour R. had eleven large thermæ, some of which could receive as many as 2000 bathers at a time, and 856 baths of an inferior order. Several of the thermæ still exist, and have been explored since 1870. The excavation of the Forum Romanum was resumed 2d April 1878, the plan of the Italian Government being to clear the whole space to the front of the Palace of the Cæsars. The workmen engaged in digging the foundations for the new quarters on the Esquiline recently discovered the Forum Esquilinum and the surrounding markets. The Palace of the Cæsars on the Palatine has been shown by recent research to have no unity either of plan or decoration, but to consist of a suite of palaces built independently of each other and at different periods. The gardens of Mæcenas on the Esquiline have been excavated, and the most interesting discovery is a splendid conservatory, the walls of which are decorated with beautiful landscapes. But perhaps the most important of all recent discoveries was that of a palace (1876) in the Horti Lamiani, containing bath-rooms of extraordinary splendour, from one of which was taken the group of sculptures now forming the chief treasure of the New Museum of the Capitol. Nearly all the foundations of the buildings in the Esquiline gardens are composed of fragments of statuary. A single wall scarcely 100 feet long yielded 2500 pieces of sculpture, out of which the archaeologist with equal patience and skill furnished the New Museum with seventeen statues and two sculptured vases. The Catacombs (q. v.), which form so interesting a link between ancient and Christian R., extend round the city in a wide circle, and, according to Michele di Rossi, cover an area of 615 acres. Pope Leo XIII., who is president of the Archaeological Society of R., resumed the work of excavation in the great catacomb of St. Calixtus at his own cost in July 1878.

The great architectural monuments of modern R. are on the right side of the Tiber, in the Borgo, or Civitas Leonina, so called because Leo IV. surrounded it with a wall (848–52) as a protection against the Saracens. Here are situated the stupendous piles of the Vatican Palace (q. v.), and the noble basilica of S. Peter's (q. v.). The Castle of S. Angelo (*Moles Hadriani*) with its massive tower was begun by Hadrian and finished in 140 by Antoninus Pius as a family mausoleum; but when the Goths conquered R. under Vitiges, it was used as a fortress, and during the feuds of the Middle Ages was a stronghold of great importance. The Ospedale di S. Spirito, established by Innocent III., embraces a general hospital for 1000 patients, a lunatic asylum for 500, and a founding institution for 3000, besides a reformatory, a refuge, and a large medical library. In the Trastevere, to the S. of the Borgo, are the church of S. Pietro in Montorio, built in 1500 by Ferdinand and Isabella; the Villa Farnesina, built by Peruzzi in 1506, and famed for its Raphael frescoes; and the

magnificent Acqua Paolo, the finest of R.'s many fountains, erected 1611. Outside the Porta S. Pancrazio, is the Villa Doria Pamfili, the most delightful and extensive of all the Roman villas. The Mausoleum of Augustus, converted during the Middle Ages into a stronghold, is now used as a theatre and circus. The Palazzo Borghese, begun in 1550, has an imposing façade, and contains the most important picture-gallery in R. next to that of the Vatican. The Palazzo Farnese, one of the finest palaces in R., begun by Da Sangallo in 1534, continued by Michael Angelo, and completed by Della Porta in 1580, has been occupied since 1874 by the French embassy. The Università della Sapienza which was founded in 1303, and attained its greatest prosperity under Leo X., Leo XII., and Gregory XVI., has still faculties of law, medicine, physical science, and philology, and possesses the *Biblioteca Alessandrina* of 90,000 vols. S. Luigi de Francesi, consecrated in 1589, is the national church of the French, and S. Maria dell' Anima (1514) is that of the Germans. S. Maria Sopra Minerva, probably begun in 1285, and restored 1848–55, is the only Gothic church in R., and contains many rare works of art. The Palazzo della Cancelleria, designed by Bramante, contains within its precincts the church of S. Lorenzo, and is a structure of majestic simplicity. Between the *Pescheria*, or fish market, and the Tiber, lies the Ghetto, still inhabited exclusively by Jews. What is known as the 'strangers' quarter,' the elegant northern part of the city, is intersected by the Corso, which corresponds to the Via Flaminia, and is now the principal street of R. and the scene of the Carnival (q. v.) festivities. Among the many notable edifices in this district are the Villa Medici (1540), which became the seat of the French Academy of Art in 1801; the Collegio di Propaganda (q. v.); the S. Carlo al Corso, the national church of the Lombards, and the resort of the fashionable world; the Palazzo Chigi (1526), with a fine picture-gallery; the Camera de Disputati, since 1871 the Italian Parliament House; the superb palaces of Colonna, Sciarra-Colonna, and Palazzo Doria, containing valuable art-collections; the church of S. Marco, rebuilt in 833; and Gesu, the gorgeous church of the Jesuits, erected 1568–77. The Collegio Romano contains the new *Biblioteca Vittorio Emanuele*, which consists of the old library of the Jesuits (63,000 vols. and 2000 MSS.), and the libraries of the suppressed monasteries (450,000 vols.). The massive building is now also the home of the new *Museo Preistorico*, the *Museo Kircheriano*, founded by the learned Jesuit Athanasian Kircher (born 1601), &c. Since the Italian occupation buildings have been rapidly springing up in the long-deserted E. part of R., and on the Esquiline in particular an entire new quarter is being erected. In this direction are the Palazzo Barberini, with important collections of pictures and sculpture, and a famous library containing 7000 valuable MSS., the Palazzo Regio (1574), formerly the Apostolic al Quirinale, but since 1870 the residence of the King of Italy, the church of S. Pudenziana, traditionally the oldest in R., and the old S. Maria Maggiore, deriving its name from its being the largest of the eighty churches in R. dedicated to the Virgin. Opposite the baths of Diocletian is the railway station. Beyond the Porto Salara is the famous Villa Albani, and in the N. is the Villa Borghese.

The temperature of R., which has a mean of 60° F., ranges in the shade from 100° in summer to 21° in winter. The pleasantest season is from the beginning of October to the end of May, after which the fever-laden *aria cattiva* prevails. With its priceless libraries and galleries, R. is a cosmopolitan home of art and learning. Its commerce and industry are gradually reviving. A railway to the port of Fiumicino was opened in March, 1878, and the port is now provided with piers and wharves. The industrial products of R. are chiefly woollens, silks, velvets, leather, glass, mosaics, jewellery, cameos, casts, photographs, and 'Roman pearls.' There is a considerable trade in antiquities. In 1877 R. had 235,302 inhabitants, and of these 29,000 were temporary residents, 5687 soldiers, 1428 secular clergymen, 2175 monks, and 1824 nuns.

While the origin of R. is traditionally referred to Romulus (q. v.), its early extension is ascribed with more certainty to Servius Tullius. Under the kings it developed rapidly, and the second or Servian wall, the Circus between the Palatine and Aventine, and the Cloaca Maxima, date from before the expulsion of Tarquinus Superbus (509). After its destruction by the Gauls (390) it was hastily re-erected, and not until the overthrow of Carthage had made it the first city of the world did its archi-

ecture begin to reflect the prevailing wealth and luxury. Caesar formed extensive architectural plans, but their execution was reserved for his nephew, and of all the existing ruins those of the buildings of Augustus are both the grandest and most numerous. The Flavian dynasty is perpetuated in the memory of R. by many imposing works, above all by the Colosseum, which has ever been the symbol of Roman power and grandeur. Under Trajan, R. attained the culminating point of art and political greatness. The name of Constantine the Great marks the latest important ruins of antiquity. Goths, Vandals, Franks, and Saracens successively destroyed and pillaged the city, and as the cultivation of the Campagna was abandoned, it was attacked by the deadly malaria. On the termination of the Papal schism (1378-1417), the city received a new impulse, quickened by the vast sums which flowed into the papal coffers, and by the revival of a taste for art and science, promoted by Nicholas V., Julius II., Leo X., and others. To Sixtus V. the modern city is mainly indebted for its characteristic features. In 1798 a republic was formed in R., which was under the supremacy of France 1809-14. A republic was again declared in 1849, but Pius IX. was restored in 1850 by the French, who placed a garrison here till 1866, and again after the Garibaldian hostilities till 1870. On the 20th September of that year the Italian troops entered R. after a bombardment of five hours. See Ampeire's *l'Histoire Romaine à R.* (3d ed. 4 vols. 1856-64), Fournier's *Rom und die Campagna* (2 parts, 2d ed. Leip. 1865), Dyer's *City of R.* (Lond. 1865), Reumont's *Geschichte der Stadt Rom* (3 vols. Berl. 1867-70), Burn's *R. and the Campagna* (Lond. 1870), Hare's *Walks in R.* (4th ed. 1874), C. J. Hemans' *Historic and Monumental R.* (1874), *Pittura e Sepolcri scoperti nell' Esquilino della Compagnia Fondiaria Italiana, nell' anno 1875* (Roma, 1876), Parker's *Archæology of R.* (Pts. I. to XII. 1873-77), and Von H. Jordan's *Topographie der Stadt Rom im Alterthum* (Berl. vol. ii. 1878).

Rome, the capital of Oneida county, New York, U.S., at the junction of the Erie Canal and Mohawk River, on the New York Central and Hudson River Railroad, 110 miles W. of Albany. It contains 13 churches, a public library, 6 banks, and the Central New York Institution for Deaf Mutes. It is the centre of a great cheese-making and dairy industry, and has considerable hardware manufactures. Pop. (1876) 11,000.

Rome. The history of the foundation of R. is lost in antiquity. If authentic records on the subject ever existed they have irretrievably perished. Lack of reliable information gave rise to numerous myths, which, though valueless as history, are yet, from the importance and interest of the subject, eminently worthy of record. It is needless to mention more than three of the many mythical accounts of the foundation of R.:—(1) R. was founded by the Pelasgi, in the age before the Trojan War; (2) By Æneas, immediately after the fall of Troy; (3) By Romulus, grandson of Numinor, on 21st April, 753 B.C. The third myth came to be generally accepted.

Ethnology.—The Romans were essentially a mixed people. They were in fact a combination of at least three distinct races,—the *Latini*, *Sabini*, and *Etrusci*. The first of these was itself a mixed race—a fusion of the Pelasgian with the early Italian stock. This amalgamation, effected at an early epoch, produced strange ethnic results, both with regard to character and creed. When with these two races the Iapygians, perhaps the primal or autochthonous element, combined, the complication became still greater. The last named possessed a language till now undeciphered and uninterpreted. The *Latini*, with whom may be classed the Umbro-Sabellians, mainly from the fact of their intercourse with them at a very early period in Italian history, had settled in Latium long before the Etruscans had set foot on Italian soil. They were, indeed, by far the most important of the races inhabiting Italy—in fact, the germ whence sprang that wondrous people the mantle of whose power for many centuries overshadowed the world. The ethnological origin and affinities of the *Latini* are clearly defined. Their language entitles them to be classed as members of the great Indo-European family (see *ARYAN*). They were, in fact, a sister race to the Hellenes. The *Latini* were, therefore, a race carried by the westward wave of civilisation from the far distant east; whether directly through Asia Minor or by the region of the frozen Danube it is impossible with certainty to say. Mommsen takes the latter view, which has been adopted by most ethnolo-

gists. According to him, the *Latini*, after entering the hilly region of Northern Italy, crossed the great chain of the Apennines, and gradually occupied the Western seaboard, driving the aboriginal tribes into the south-eastern corner of Italy, and cooping them up in the Calabrian Peninsula. In these remote times the latter lost their distinctive character by the influx of the Hellenic element. Rich and powerful Greek colonies were planted all along the shores of Southern Italy (see *MAGNA GRÆCIA*), eradicating the pre-Latin races, and leaving here and there only a word or relic to indicate faintly their origin; while at a later period Samnite hordes, coming down from the highland districts, still farther obliterated their distinctive character. Even the Samnite colonists themselves lost somewhat of their Italian traits in their lowland and southern homes. In Latium alone the *Latini* took deep and lasting root. No Greek colonies were founded there, and no Græcising element for long appeared in the neighbourhood of the little city which, from small beginnings, was to cover the Seven Hills and wield the sceptre of the world.

The Sabines and Umbrians entered Italy at a later period than the *Latini*, and took up their position in the highland districts N.E. of R. The chief of the tribes of this warlike and vigorous people were the Picentes, Peligni, Marsi, Aequi, Vestini, Marrucini, Samnites, Volsci, and Hernici. The origin of the Etruscans has hitherto proved one of the insoluble problems of history; but the recent researches of Corssen, Taylor, Sayce, and others in the language of this mysterious people give considerable hope of its ultimate solution (see *ETRURIA*). Freeman considers that most likely they were an Aryan people; but their language, quite different from that of the other nations of Italy, seems to bear strongly against such a supposition. Indeed, it points distinctly to a Turanian origin. Besides these three peoples another claims attention. Just as the Greeks settled in and occupied the S. in pre-historic times, the Gauls, a Celtic race, and consequently a branch of the great Aryan family, at a period much later, and almost within historical times, acquired the N. of Italy. This race, however remotely connected with the other Italian races, had in pre-historic times fixed their habitat in Gallia Transalpina. Of a restless and impetuous nature, they turned their steps to the E. and S.E.—the Atlantic barred their westward progress—crossed the Alps in the 3d c. after the foundation of Rome and settled in the fertile valley of the Padus (*Po*). In this invasion the Galli Insubres took the lead. Their capital was Mediolanum (*Milan*). Other tribes soon followed, the Cenomani, who occupied Brixia (*Brescia*) and Verona, the Boii, and the Senones who crossed the *Po* and took possession of the modern Romagna, occupying the Adriatic coast as far as Ancona. The Alps formed at first a boundary between the Gauls and the Etruscans and Umbrians, but when the former penetrated to the S. of the natural barrier the terms Gallia Cisalpina (*i.e.*, on the Italian side) and Gallia Transalpina (on the farther side) became the recognised designations of the two territories. The Padus also formed a boundary-line that gave to its river-banks a distinct nomenclature: Gallia Cispadana and Gallia Transpadana. Lastly, the Greeks, immigrating into Italy in pre-historic times, colonised the southern portion of the country. They settled mainly along the coasts, built cities and established commercial relations with neighbouring countries. But the fine and plastic culture of Athens was destined to enter R. through this channel, and the first writer of note in Italy was Livius Andronicus (q. v.), a Greek slave. The literature and culture of R. was a borrowed element, the warlike spirit was alone their own.

Primitive Condition of the Latins.—The Latins must be viewed as the people of the country. In pre-historic times they were the race *par excellence*. Their region was the Plain (Latium). Whether the term Latium is radically connected with *latus*, a side, inasmuch as it was a 'sideland' is open to doubt. The derivation from *latus*, 'wide,' Gr. *platus*, Eng. *flat*, seems to have more significance. The ancient traditions lead us back to the time when Saturnus hid (*latus*) on the W. of Italy from the anger of Jove, the name *Latium* denoting the place of his concealment.

The organisation of the Latins is purely a matter of conjecture. They were originally 'Nomads,' wandering herdsmen. But this condition ceased at an early period in their history. Ennius has written the character of his countrymen in a line:—

'Bellipotentis sunt magi' quam sapientipotentis.

War, not philosophical or even agricultural occupations, engaged their attention. The language of the people goes far to bear

out this statement. They were certainly, to begin with, tillers of the soil and gatherers of its fruits. The terms *Siculi* ('sickle-wielders') and *Opici* (Opisci, 'field-labourers') establish the fact. But the oldest agricultural terms clearly prove that the Greeks and Latins sprang from the same stock. The terms *oinos, vinum; hortus, hortus hortiortus* (Scotice *stour*), and the form of the plough point indubitably to a common origin of the Greek and Italian races. *Zancle* and *Drepanum* are enduring evidences of the earliest pursuits of the people as well as of the configuration of their towns. The terms *toga* and *tunica* in Latin are merely forms of the Greek *cheiton* and *himation*. Their modes of building, wine-making, gardening, clothing, were, if not an accurate copy, in many respects kindred with those evolved by their Greek brethren. Socially their characters differed, and especially as to their ideas of infant training. The vigorous and stern regime of Sparta had no place even among this stern and semi-barbarous people. To them the milder forms of Athenian discipline were probably unknown, or, if known, were alike unpractised and unheeded.

Early Roman Political Life.—The 'state-life' of the Italians, if we are to trust tradition, was of very early growth. It was transmitted from the Hellenes. So, too, were their habits in a somewhat marked degree, as well as their social institutions generally. The *pagi* or clan-villages were quite independent of each other. Each had its own magistrate. The *pagi* were local centres with a certain religious status, and possessing the privilege of performing certain religious rites, just as by the *Comitia Calata* afterwards; the fast days and feast days, the court days and market days, were arranged and fixed by the representatives of the clans.

A centre like that of which we have been speaking was termed a *Capitolium* (*head* or *height*), from its being situated on a hill top (*cf.* Gr. *akron*). Round this strong place houses were built surrounded by the *oppidum* ('work,' from *opus*), or by the *urbs* ('ringwall,' *cf.* *urvus, curvus, orbis*). So grew the Latin towns from small beginnings. But in the mountainous districts of Italy, especially in those of the Marsi, *Æquicoli*, and among the inhabitants of the highlands of Umbria, these mysterious strongholds ringed with walls along the beetling cliffs remained, as if to mock the Roman antiquary, while they evoked his wonderment, in their primitive form. (See *Frobert. de Assisio*, v. i. 125, *et seq.*)

The earliest of these centres are to be found on the Alban hillsides. The chief consideration in their selection were fine air, fresh water, secure position. Alba Longa is probably the oldest of them all. Lanuvium, Aricia, and Tusculum were of little later birth. Tiber, Præneste, Gaiii, Labici, Nomentum, the coast cities of Laurentum, Lavinium, and the 'City of the Seven Hills' were the most important of the primitive Latin centres. It is impossible, from the want of definite information on the point, to determine the order of their constitution, or to fully estimate their relative political influence in prehistoric times; but it may be safely asserted that R. was one of the latest, as it certainly was of all the most powerful, political centres of the Latin people. With Curium it formed an alliance at an early period in its historic and national life. Constantly and persistently through the gradual rise of an undisputed sovereignty, and long after, when the conquests made abroad began to threaten its stability, R. was ever ready to accord the right of citizenship to its allies and conquered foes. *Roma Nutrix* was its motto. And herein lies its distinctive and unique character in history—the secret of its great and enduring power.

Rome during the Regal Period.—The legends regarding the origin of R. have already been noticed. According to the most popular myth, it was founded by Romulus, a son or descendant of Æneas. We dismiss for the moment the descent of the founder from Mars and Ilia—a late invention, for the glorification of the Roman State. It is much more likely that R. (comp. Gr. *Romē*, 'strength') owed its origin to its position as an outpost to guard the frontier or border-land against the Etruscans on the opposite bank of the Tiber. Like the old Greek cities, R. was at first governed by kings, aided by a senate and a popular assembly. Its monarchs, however, unlike those of Greece, were not hereditary. The first four kings seem—if we trust the legend—to have been chosen from the Romans and Quirites of Curium. It is not unlikely, from the league existing between the two cities, that this was the practice. The last three are the dynasty of the Tarquinius. Here we begin to tread on, if still unstable,

comparatively firmer ground, and to find that we are dealing with real persons. All of the Tarquins seem to have been foreigners, perhaps Etruscans. The buildings with which they adorned the city, and their traditional patronage of art, go far to bear out their Etruscan origin. Be that as it may, under their rule the power of R. grew daily. The last of them, surnamed *Superbus* from his despotic and haughty conduct, was driven from the throne, B.C. 509, about the very time when the tyrant Hippias was expelled from Athens. Putting aside, as history, the Romuleian and Pompilian myths, we must nevertheless notice these as reflecting more or less the early development of Roman civilisation, and the gradual growth of a great and potent state. The Palatine Hill was the earliest settlement of the rude band destined to conquer and control the neighbouring tribes. The Asylum or the Capitoline was certainly of very ancient date (see *CAPITOL*). So, too, were the ancient fortresses on the Capitoline and Tarpeian heights. The legendary wars with Tatius, the beautiful yet tragic legend of Tarpeia, and other myths of that early time, do not, we believe, contain in them much of reality, but they certainly point to an early alliance between the Romans and Sabines. The tale of the *Rape of the Sabine Women*, and the record by Livy of the wars with the people of Cænina, Antemnæ, and Crustumium, are in themselves valueless as history; but they point emphatically to the beginnings of a warlike race, and indicate clearly the irrepressible spirit of aggrandisement which from century to century characterised the Romans. It is barely necessary to refer to the reforms of the kings who succeeded Romulus, to the myths of Egeria, of Tanaquil, and the Sibylline leaves. These every scholar has long since learned to estimate at their proper value. What is known as the history of this period was concocted centuries after the events occurred, and long after all records had perished, by chroniclers who were anxious to construct a probable theory of their nation's being and begetting, and to do so in consonance with the national feeling and to the fostering of the national pride.

The natural as well as the earliest division of all peoples includes two classes, freemen and slaves—*i.e.*, 'householders' and their 'dependents.' So it was in R. The former were termed *patricii* (from *pater*, 'a father'), the latter *servi* (from *servus*), but at a very early period in the history of R. there was a distinct class—the *clientes*, *i.e.*, the 'listeners' (from *luere*, 'to listen'). These were dependents on the original *populus*, who alone possessed Burgess rights. The *populus* had a political, the *clientes* a non-political existence. How the *clientes* originated, and whence their inferiority arose, cannot now be ascertained. The opinion of those who have given much attention to the subject is that they were a conquered race. Still, the *patricii* and *clientes* had reciprocal duties to discharge, and these were sacredly observed. The *patronus* was bound to interpret and expound the laws (*promere leges*) to his client, and to watch over his personal interests. The client, on the other hand, was bound to support his patron; to furnish a dowry to his daughter if required, and to ransom his patron if the latter happened to be taken prisoner in war. The two, moreover, could not appear against each other in a court of law or assume a hostile attitude in anywise. In connection with this subject we adopt the ingenious hypothesis of Niebuhr. The following propositions express his views:—(1) The plebs and clients were originally distinct. (2) The original Roman population consisted of patricians and clients. (3) The plebs were the inhabitants of conquered Latin towns transported to Roman territory. (4) The term *populus* included the patricians and clients: the term *plebs* those mentioned in 3 *supra*. The plebs (from *pleo*, 'to fill') were therefore clearly of later date than the *clientes*. In short, the *clientes* were attached to the original Roman people long before the plebeian element was politically entertained or acknowledged. The plebs were the *vulgus* (digammated form of Gr. *ochlos*, Eng. *folk*).

The primitive constitution of the Romans was very simple, in fact, based on the family relation. The whole people must be viewed as a *familia*. From among themselves they chose their king (*rex*), who was looked up to as the *genitor*, or father of them all. Hence the uncircumscribed nature of his functions—the absolute power conveyed by the expression *patria potestas*. The *rex* of the Romans, like the *lucumo* of the Etruscans, was priest as well as king. The consultation of the gods, the declaration of war, and the conclusion of peace, the highest political

and military power (*summum imperium*), by which must be understood the debts, duties, and obligations of the ruler as well as the supreme military command, were all vested in this chosen 'leader.' On all great occasions he was preceded by the *lictors*, 'summoners' (from *licere*, 'to summon'), bearing the *fascēs* (axes and rods), denoting that invincible power which is the birth of union and that unswerving justice whose prerogative is death.

Though the sole power was in the hands of the king, subordinate officers, from an increase of 'state duties,' were gradually appointed. Such were the *præfectus urbi* (city warden), the *quæstores parricidii* (trackers of heinous murder), the *tribuni militum* and *tribuni celerum*, all of whom were merely, in Mommsen's view, *commissioners* rather than *magistrates* in the later meaning of the term. The *Senatus*, or advising council (from *senex*), composed of ten elders, was coeval with the monarchy. The members thereof held office for life. The burgesses were divided into *Curie* (*curiæ*) or wardships, probably so called from *cura*, *curare* ('to care for'), with special reference to the supervision of the *curio*, the superior officer or warden of each. Varro connects the title *curio* with *quiris* ('a spear'), and *Cures* the capital of the spearmen of Sabinum; but this, like most of the derivations of the early Roman writers is purely fanciful. A special priest (*flamen curialis*) managed the religious ceremonies and festivals of each ward. See COMITIA and GENS.

Aggrandisement was from the first the policy of R. The 'Long White City' (*Alba Longa*), the sacred capital of Latium, was absorbed by the strong outpost. Sometimes, in the case of a conquest of a neighbouring city, the dwellers were allowed to remain after the destruction of the *Arx* or *Capitolium*. Sometimes the conquered tribe was transferred to the city of the victors. The gods of the subjugated were, however, invariably removed to R. In the case of *Alba Longa*, the citizens were granted equal rights with the Romans. Many of the greatest families in the later history of R. were proud to boast of their Alban lineage. The Julii, Servilii, Quintilii, Cloelii, Curii, &c., claimed from *Alba*. The earlier wars with the Fidenates and Veientes, and the struggle with the Rutulians and Volscians, though apparently all in favour of R., are the inventions of a later time. Even the conquests of the Tarquins are hazy in the extreme. The Roman Assemblies are treated under the article COMITIA.

The Commonwealth.—The history of R. is even at this period very uncertain. Legends, fine though they be, cannot be accepted as history. A foul outrage on Lucretia, the wife of Tarquinius Collatinus, is said to have led to the expulsion of the kings. There is little doubt as to the actual dethronal of Tarquin, but the real cause and the time (509 B.C.) are, seeing that the account was written ages after, matter of uncertainty. When the kings were driven out, *prætors* (from *præ* and *eo*) took their place. They were afterwards called *consuls* (from *cum* and *sedeo*, 'to sit,' or *salio*, 'to leap'), and held office for a year only. The patricians had long the right of electing them. The first plebeian consul was not elected till 366 B.C.

The legends of Valerius Publicola, Spurius Lucretius, M. Horatius, Lars Porsena of Clusium, Aulus Postumius, and the thrilling stories of Horatius Cocles and the battle of Lake Regillus will not bear scrutiny. The first act of R. was to make a league with Carthage, both on her own behalf and in the interest of the Latin states. But the Æquians and Volscians continued to cripple her. The conquest of Veii in 396 B.C. by Camillus materially added to her power; but her defeat by the Gauls at Allia in 390 B.C. more than counterbalanced the former victory. The invasions of the Gauls told severely on R. and though in the end she was victorious, her progress was greatly retarded thereby. In 343 B.C. began a series of wars which lasted more than half a century. The first was with the Samnites—no despicable foe. The next was with the Latins, the result of which was the breaking up of the Latin League. In 326 B.C. the second Samnite war broke out, lasting eighteen years, and in 298 B.C. a third extending over eight years. By 282 B.C. R. had acquired all Italy with the exception of the cities in *Magna Græcia*. About this time the Tarentines gave offence to R. and asked the aid of Pyrrhus, King of Epirus. He responded to their invitation, and the Romans had to face under a new mode of warfare the greatest warrior of the day. He defeated them in two battles, but with so great loss to himself that he was glad to leave the country. He returned in 276 B.C., was defeated at Beneventum, and left

Italy for ever. The conquest of all Italy by R. soon followed. She now turned her eyes to Carthage, a headship like herself, with many Phœnician cities in Africa under her sway, and possessing, moreover, as a great trading power, large territories in foreign lands. Sardinia, Corsica, and a large portion of Sicily owned her rule. In Sicily a cause of quarrel arose. R. undertook the protection of the Mamertines, who had seized the town of Messina (see HIERO). The struggle that ensued is known as the First Punic War. It began 264 B.C., and lasted twenty-four years. Regulus (q. v.) carried the war into Africa. But the power of Carthage lay in her fleet. R. was not a commercial power, and as yet possessed no navy, but she learned a lesson from her enemy; and a stranded Carthaginian vessel enabled her to construct a fleet with which she gained a brilliant victory (241 B.C.). The Carthaginians sued for peace; and Sicily became, with the exception of Hiero's dominion, a Roman province. After twenty-three years the Second Punic War broke out. While R. had increased her strength by the acquisition of Corsica and Sardinia, Carthage had secured her position in Spain, and immense territory had been acquired there by Hamilcar (q. v.), Hasdrubal (q. v.), and Hannibal (q. v.). The details of this war are so fully given under these lives that nothing more need be said here. See, moreover, the lives of *Metalus*, *Fabius*, *Marcellus*, *Scipio*, and the articles CARTHAGE and NUMIDIA. The battle of Zama ended the conflict (202 B.C.), Carthage surrendering all her foreign possessions. The Third Punic War occurred in 149 B.C. This was the last attempt by the Carthaginians to recover their lost prestige. Carthage was taken by the younger Scipio in 146 B.C., the year in which Corinth was destroyed by Mummius. The territory was divided between the Numidian king Massinissa and R. The share of the latter became the province of *Africa*. In 229 B.C. war broke out in Illyria. The island of Corcyra and the Greek cities of Epidamnus and Apollonia submitted to R. In 215 B.C. Philip of Macedon leagued with Hannibal, and in 213 B.C. the First Macedonian War broke out. Peace was concluded in 205 B.C. The Second began in 200 B.C., and ended in 197 B.C. with the defeat of Philip at Cynoscephalæ. The conquest of Ætolia soon after gave to R. the control of all Greece. The Third Macedonian War broke out in 171 B.C., and closed with the battle of Pydna, 168 B.C. The Fourth and last of these wars broke out in 149 B.C., and ended in the following year with the defeat of Andrisos. Corinth succumbed in 146 B.C., but Athens and several of the Greek cities retained a nominal independence. R. now turned to Asia. The defeat of Antiochus at Magnesia in 189 B.C. by Lucius Scipio, forms the first great event in her Asiatic conquests. The Seleukid kings were thereafter shut up in the small kingdom of Syria, and Western Asia became a Roman possession. In 133 B.C. Attalus, the last king of Pergamus, bequeathed his dominions to R. Cisalpine Gaul was acquired in 191 B.C., Liguria and Venetia soon after. Spain was next wrested from the Carthaginians and native races by the indomitable valour of the Scipios. R.'s dominions in Spain may be said to have been completely established by the taking of Numantia, 133 B.C. Only a few native tribes in the N. retained then freedom. The conquest of Transalpine Gaul soon followed. In 125 B.C. part of it became a Roman province—a name which it still retains (*Provence*). The wild hordes of the Cimbri and Teutones for a time barred the progress of R. The latter were utterly defeated in 102 B.C. by Caius Marius, and the Cimbri in the following year by the consuls Marius and Catulus.

We will glance now for a moment at the internal condition of R. From the beginning of the Samnite wars to the conquest of Numantia she had become the mistress of many nations, and these she ruled with a sovereign power. The *Provincials* and *Allies* had no part in the settlement of national questions. The plebeians and patricians now stood on the same legal footing. The government was thoroughly *democratic*: the people were the lawgivers. Still there continued to exist a large amount of the *aristocratic* element, and the nobles fought strenuously for the retention of their ancient rights and privileges. The strife between the patricians and plebeians was succeeded by one of still more threatening aspect—that between the *rich* and the *poor*. The cause of the latter was undertaken by the Gracchi (q. v.). Then came the Jugurthine War, 111–106 B.C.; the Social or Marsic War, 90–88 B.C.; the Civil War between Marius and Sulla; the Mithridatic Wars, 88–84, 83–81, 74–64 B.C.; the Servile War, 73–71 B.C.; and the Catilinarian conspiracy, 63 B.C. In 54 B.C.

Crassus was defeated in Parthia. A tolerably full account of the events of this and of the immediately succeeding period will be found in the lives of *Sertorius*, *Lucullus*, *Crassus*, *Pompeius*, *Mithridates*, *Cæsar*, *Cicero*, *Catiline*, *Mark Antony*, *Lepidus*, *Cleopatra*, *Clodius*, *Brutus*, *Cassius*, and *Cato*. It is therefore unnecessary to repeat it here. After the death of Cæsar 44 B.C. confusion reigned for thirteen years. This period includes the Second Triumvirate; the wars between Brutus and Cassius on the one side and Antony and Octavius on the other; the amours of Antony and Cleopatra; the war between Octavius and Antony, which ended in the defeat of the latter and Cleopatra at Actium, B.C. 31. Egypt now became a Roman province, and Octavius was undisputed master of the Roman world.

The Empire.—On the return of Octavian, B.C. 29, he was the idol of the senate and people, and honours were heaped on him on all sides. In 27 B.C. he was voted the title of Augustus (q. v.). This date marks the beginning of the empire. R. was rapidly advancing to the plenitude of her power. When Augustus died (14 A.D.), she had extended her dominion over the civilised world. Her dominion was bounded by the Rhine, the Danube, the Euphrates, and the great African deserts. In her western provinces, her customs and language took deep and lasting root. Her civilisation there was all but universal. In the Greek-speaking provinces the Greek language and culture maintained their ground. But centuries after, the Greek people paid homage to the Roman power in a signal degree, surrendering the very name of their language, the Greek or Hellenic, for the still enduring term *Romæic*. In the distant nations of the East the native languages, religions, and modes of thought still survived. The Roman franchise was gradually extended to the province, and in course of time all the free inhabitants under the sway of R. were granted citizenship. The absolute rule of a single individual became from day to day more firmly established, and old distinctions gradually disappeared. The most important event that marks the reign of Augustus is the birth of Jesus Christ. Now, too, was the golden age of Latin Literature (q. v.). After Augustus come the Claudian emperors: Tiberius (q. v.), Caligula (q. v.), Claudius (q. v.), Nero (q. v.), and the Flavian emperors in rapid succession, Galba (q. v.), Otho (q. v.), and Vitellius (q. v.), all—with the exception, perhaps, of Galba and Otho—presenting in their lives a fearful and grim chronicle of crime, lust, and debauchery. Nevertheless, owing to the internal peace that had obtained since the accession of Augustus to imperial power, the material prosperity of R. had increased, and the population had been nearly doubled. But, withal, the rich were rapidly becoming more degenerate, especially the females; and men who were called virtuous preferred concubinage with a slave to marriage with a Roman lady, however high her rank. In the year 70 A.D. Vespasian (q. v.) inaugurated a better era, which, Domitian's reign excepted, lasted for a century. He was succeeded by his son Titus (q. v.), 79–81 A.D., an emperor whose noble character and imperial bearing secured for him the title of the 'Delight of Mankind.' His brother Domitian (q. v.), who succeeded him, and was killed in 96 A.D., was one of the greatest tyrants of R. The reigns of Nerva (q. v.), 96–98 A.D., of Trajan (q. v.), 98–117 A.D., under whom the Empire may be said to have attained its greatest extent (see MAP), of Hadrian (q. v.), 117–138 A.D., of Antoninus Pius (q. v.), 138–161 A.D., and of Marcus Aurelius, 161–180 A.D., known to history as the good emperors, were all characterised by signal ability, moderation, and dignity. How far the salutary change in rule and morals was due to the fast-spreading religion of Christ we cannot say, but that its influence was both widely and deeply felt is unquestionable. The acts of the above-mentioned emperors will be found in their biographies. Marcus Aurelius was succeeded by his son Commodus (q. v.), a monster of vice and cruelty, with whose reign begins the decline of the Roman Empire. But R. took centuries to fall after all hope of her stability was lost. The names of the emperors during the next century (192–285 A.D.) need not all be given here. They were set up by the soldiers and slain by them at will. In the reign of Septimius Severus (193–211 A.D.), the Christians obtained a certain amount of recognition, and their religion made rapid strides. The government, too, became daily of a more military character. Severus was succeeded by his son Antoninus, generally called Caracalla (q. v.), after whose murder Elagabalus and Alexander Severus, the former one of the basest, the latter one of the best of emperors, occupied the throne.

After the assassination of Severus, a fearful period of anarchy and confusion followed. The names of Maximin Maximus, Balbinus, Gordianus (q. v.), and Philip recall scenes of internal strife only paralleled by the ferment beyond the Roman frontier. Frank, Swabian, and Goth were alike ready to swoop down on the Empire. During the reigns of the succeeding emperors—Valerian (q. v.), Gallienus (q. v.), and the *Thirty Tyrants*—the Empire was a scene of wild disorder. The most famous of the Greek cities were burnt and pillaged by the Goths, while the Asiatic hordes devastated the province of Asia. By the valour and skill of Odenathus, husband of Zenobia, Queen of Palmyra, the progress of the latter was checked. Zenobia's kingdom was afterwards suppressed by Aurelian, one of the ablest of the Illyrian Emperors (271 A.D.). Claudius Gothicus (268–270 A.D.), Aurelian (q. v.), Probus (q. v.), and Carus were all employed in crushing the barbarians; and when Diocletian (q. v.) assumed the purple (284 A.D.) the worst seemed to be over. He instituted a new order of things. The Empire was now to be governed by two *Augusti*, and two *Cæsars* subordinate to them. A series of civil wars ensued, in which the more prominent names are those of Maximian, Constantius, Galerius, Maxentius, Maximin, Licinius, and Constantine (q. v.). Under the last the Empire was again re-united. He began his reign at York (*Eboracum*) in 306 A.D., obtained the whole Empire 323 A.D., and reigned till 337 A.D. Under his rule two events occurred, both pregnant with great results—the establishment of Christianity as the state religion, and the transference of the government to Byzantium (q. v.). The partition of the Empire among his three sons again led to mutiny and disunion. But the political history of the Empire is now of secondary interest. The fortunes of the Catholic Church have a greater charm for the historian. The freshness and newness of life thereby imparted to the effete Empire saved it from disappearing for ever from the roll of mighty nations, and enabled R. to reap, centuries after, a rich harvest from the culture of the past. Of Julian's frantic attempt to revive paganism, we need only say that it was mistimed and ill judged. All succeeding Emperors professed Christianity, and the Christians soon formed a majority in the land. Under Valentinian (q. v.), Gratian, and Theodosius (q. v.), the pagan creed came to an end. These three Emperors were all men of signal mark; but 'the beginning of the end had come.' The integrity of the Empire was gone, and foreign foes, like ravenous vultures, were hovering round the rotting carcass. On the death of Theodosius, Alaric (q. v.), with his West Goths, rose against Honorius (q. v.), Emperor of the West. The bravery and tact of Stilicho (q. v.) for a time paralysed the foe and stemmed the torrent of invasion; but in 410 A.D. they sacked Rome, now first taken by a foreign enemy since the days of Brennus (q. v.), the Gallic chief. Franks, Burgundians, Vandals, Teutons, had not only attacked, but obtained a settlement in, the Empire. On their heels followed Turanian hordes, led by Attila, King of the Huns. He was defeated at Châlons in 451 A.D. by the united powers of the Romans, Goths, and Franks. 'This,' says Freeman, 'was one of the most important battles in the history of the world: it was a struggle for life and death between the Aryan and Turanian races; and Christianity and civilisation, and all that distinguishes Europe from Asia and Africa, were at stake.' The only Emperor now worth naming is Majorian (457–61 A.D.), a man whose character for bravery and wisdom entitles him to lasting remembrance. In 476 A.D. Romulus Augustulus, the last Emperor of the West, who by a singular coincidence bore the names of the founder of the city and the founder of the Empire—a weak and pusillanimous creature—was dethroned by Odoacer, King of the Heruli, who now claimed from the Emperor of the East the sovereignty of Italy. The Eastern or Greek Empire, however, continued to exist for nearly a thousand years longer, until in 1453 A.D. it was overthrown by the Turks (see BYZANTINE EMPIRE). Consult the ancient histories of Polybius, Cæsar, Livy, Sallust, Tacitus, &c., and the modern histories of Gibbon, Niebuhr, Arnold, Merivale, and Mommsen.

Romford, a market-town of Essex, 12 miles E.N.E. of London by rail, has a large parish church, rebuilt in Decorated style (1850), a townhall, corn exchange (1862), courthouse, and literary institute, and publishes two newspapers. Brewing is the principal industry, 'R. ale' being widely celebrated. Pop. (1871) 8239.

Rom'illy, Sir Samuel, the son of a jeweller, was born at London, March 1, 1757. While a law student he visited Geneva, where he formed the foundation of a lifelong friendship with Dumont; and at Paris he became intimate with Diderot, D'Alembert, and many of those who subsequently took prominent positions in the Revolution. His interest in the cause of liberty in France was intense; several times he crossed the Channel to mix among the revolutionary politicians, with whom his correspondence was constant. In 1789 he drew up for the benefit of the National Assembly a treatise which Mirabeau translated under the title of *Reglemens observés dans la Chambre des Communes*, and in the same year he wrote a pamphlet called *Thoughts on the Probable Influence of the French Revolution on Great Britain*. Before that time a tract of his, *A Fragment on the Constitutional Power and Duties of Juries*, had obtained considerable notice. In 1792 he translated some observations of Dumont's upon the events of 1789, under the name of *Groenvelt's Letters*. By 1806 he had attained a larger practice than that of any other barrister in the Chancery Court, and in that year he was appointed Solicitor-General by the Fox and Granville Ministry. He was then knighted. He sat in Parliament successively for Queenborough (1806), Horsham (1807), Arundel (1812), and Westminster (1818). R. had a large share in the management of Melville's impeachment and trial, and effected considerable changes in the bankruptcy laws; but the greatest of his reforms was the amelioration of the criminal code, his first pamphlet on this subject appearing at a time when nearly 300 offences were punishable by death. Lady R. died in October 1818, and her death so preyed upon the mind of her husband as to cause him to commit suicide on the 2d of November. His speeches were collected in 1820; in 1840 appeared the *Memoirs of the Life of Sir Samuel R.*, written by himself, with *Selections from his Correspondence*, edited by his sons.—**John, Baron R.**, son of the preceding, born in London, 1802, graduated at Trinity College, Cambridge, in 1826, and in the following year was called to the bar at Gray's Inn. He sat in Parliament as a Liberal from 1832 to 1835, and from 1846 to 1852. He was knighted and made Solicitor-General in 1848; in 1850 he became Attorney-General and a privy councillor; and in 1851 he rose to the position of Master of Rolls. It was he who caused the publication of the *Rolls Series of Calendars of State Papers*, and other historical papers. R. was raised to the peerage on January 3, 1866, as Baron R. of Barry, Glamorgan. He died at London, December 23, 1874.

Rom'ney, George, a famous portrait painter, was born at Dalton-in-Furness, Lancashire, 15th December 1734. He was brought up to his father's business of cabinetmaking, but at the age of nineteen was placed with Steele, a painter at Kendal, with whom he remained for five years. In 1756 he married, and after practising at York as a portrait painter, removed to London in 1762. Rapidly attracting public attention, and making many influential friendships, he became in the course of a few years the successful rival as a portrait painter of Reynolds and Gainsborough. In 1773 he visited Italy, and returning two years later, continued to work in London and at Hampstead till 1799, when he retired to Kendal in broken health to join the wife whom he had only visited twice in thirty-seven years. He died at Kendal, 15th November 1802. In his later years he gained a high reputation as a painter of historical subjects. Several of his works are engraved in *Boydell's Shakespeare*. He never exhibited at the Royal Academy or sought academic honours. Lacking the delicacy of Reynolds and the charming vivacity of Gainsborough, and ranking below either as a colourist, R. yet surpasses both in intense dramatic feeling and a passionate sense of female beauty. See the elaborate Life by the poet Hayley (1809); a briefer one by the Rev. John R., son of the painter (1830); and *English Art under George III.*, by Sidney Colvin, in the *Fortnightly Review* for March 1874.

Romorantin (Lat. *Rivus-Morentini*, 'the bank of the river Morantin'), a town in the French department of Loire-et-Cher, situated on the Soudre, an affluent of the Cher, 25 miles S.W. of Blois. It manufactures cloth, oil, and sword blades. Pop. (1872) 6667.

Rom'ulus, the mythical founder of the city of Rome. He was the twin-brother of Remus, and the son, by the god Mars, of the vestal Rhea Silvia, daughter of Numitor, who had been deposed

by his brother Amulius from the throne of Alba. Thrown in a cradle into the Anio, the infants were drifted into the Tiber, and left on dry land by the receding river at the foot of Mount Palatine. There they were miraculously suckled by a she-wolf, until found by Faustulus, the king's shepherd, who brought them up with his own children. When they learned their paternity, they rose against Amulius, defeated and slew him, and restored their grandfather to the throne. Now, however, they longed to erect a city on the spot where they had spent their years of infancy, and accordingly the site of Rome was chosen. Disputes arose between the brothers, which ended in Remus being slain by the hand of R. R. made his stronghold an 'asylum' for every desperate stranger, and soon found himself at the head of a horde of exiles, robbers, murderers, and runaway slaves, to provide wives for whom he perpetrated the celebrated rape of the Sabine women. This act led to a series of wars with the Sabines, which were ultimately settled by an incorporating union between the two peoples. R., after reigning thirty-seven years, and enacting many wise laws, was carried up to heaven by his father Mars. Such was the form which the myth assumed in the hands of successive poets and historians. It cannot be considered as having even any traditional historical value. 'The early legends must be considered,' says Professor Seeley, 'not as exaggerations or perversions, however extravagant, of incidents which really happened in the 8th c. before Christ, but confused and imaginative attempts to account for institutions and worship which existed in the third and fourth centuries.' See Professor Seeley's edition of *Livy*, Book I. (Oxf. Clarend. Press, 1871).

Rom'ulus August'ulus. See ODOACER.

Ronaldshay, N. and S., two of the Orkney Islands (q. v.).—**N. R.**, the most northerly of the Orkneys, is 3 miles long by little more than 1 broad. The land is tolerably fertile, and fish and seals abound on the coast. Pop. (1861) 532.—**S. R.**, 6 miles N.E. of Duncansby Head, is about 9 miles long, and from 2 to 5½ broad, with an area of about 18 square miles. A considerable part of the land is loamy and very fertile, wild fowl are abundant, and the fisheries are rich in cod, herrings, and lobsters. St. Margaret's Hope, Water Sound Ferry, and Widewall Bay are excellent harbours. Pop. (1861) 2551.

Roncesvalles ('Briar Valleys'), a Pyrenean valley of Navarre, 23 miles N.N.E. of Pamplona, where in 778 the rear-guard of Karl the Great was treacherously cut off by the Basques, Roland (q. v.) falling in the action. Near the same spot the Spaniards were defeated by the French in 1794, and Soult was forced from his position by Wellington, July 28, 1813.

Ronciglio'ne, a town of Central Italy, province of Viterbo, on the margin of the Campagna di Roma, 34 miles N.N.W. of Rome. It is well built, and has a Gothic cathedral and a castle, extensive iron and copper works, and manufactures of cottons, powder, soap, and hats. Pop. (1874) 6084.

Ron'da, an ancient Moorish town of S. Spain, province of Malaga, 41 miles W. of the town of that name. It is situated on a rocky plateau, surrounded on three sides by the Tajo de R., a precipitous ravine more than 650 feet deep, crossed by two bridges. The magnificence of the scenery and the salubrity of the town attract many summer visitors from Seville and Malaga. R. has several churches, a large circus for bull-fights (held annually in May during the eight days' market), and a fine alameda. The inhabitants manufacture cloth, knives, oil, and armour. Pop. 14,100. R., the *Arunda* of the Romans, was the chief fortress of Granada under the Moors. It was taken by the Spaniards in 1485.

Ron'deau, Rondo, or Rondel (Fr.), literally something that goes round, or returns upon itself; hence, a short poem of from one to three stanzas, each of which ends either with the first two or three words, or with the first or first two lines of the first stanza. Originally peculiar to French literature, it consisted in the 14th c. of eight verses, of which the first was repeated in the middle, and the two first were the same as the two last. In the 15th c. it was usually divided into three stanzas, the second and third of which ended by repeating the first or first two verses of the first, the total number of verses being twelve to fourteen, running on but two times.

Bon'do (Ital.), in music, a light form of composition, consisting of two or more strains, the first recurring at the end of each of the others, which conduct the ear naturally back to it. It is thus in music what the *rondeau* is in poetry. The R. often forms the last movement of a symphony and sonata, though it is also popular as an independent composition.

Bong'e, Johannes, born at Bischofswalde in Silesia, October 16, 1813, proceeded from the Neisse gymnasium to the University of Breslau (1837). He received the chaplaincy of Grottkau (1840), but was suspended for an article *Rom und das Breslauer Domkapitel* (1842), and became a teacher at the Laura-hütte ironfoundry. A second article, this time denouncing the exhibition of the Holy Coat of Trier as idolatrous, was followed by his excommunication (1844), and straightway R. appeared as the founder of a new sect, the 'German Catholics' (q. v.). From religion he turned to politics, and for his part in the Revolution of 1849 was forced to take refuge in London, whence in 1851 he issued with Kinkel and Ruge an *Aufruf an das Deutsche Volk*. On the publication of an amnesty (1861) he returned to Breslau, established the Religious Reform Association at Frankfurt (1863), and since 1873 has lived at Darmstadt.

Bönn'e, the chief town in the island of Bornholm (q. v.), has a fine harbour, large fisheries, and a considerable commerce. Pop. (1874) 5505.

Bon'sard, Pierre de, born at the Château de la Poissonnière, in Vendomois, 11th September 1524; after six months' schooling at the Collège de Navarre became page to the Dauphin (1534), and on that prince's death to the Duc d'Orléans (1536). A twelvemonth later he entered the household of James V. of Scotland, but after three years spent at the Scottish and a half-year at the English court, returned to France, and served as secretary to De Baif, ambassador to the Diet of Speier, and to Du Bellay, whom he accompanied to Piedmont. It was at the close of this last journey that R., then eighteen, was attacked with the 'fortunate' deafness which turned him from diplomacy to letters. Familiar with English, German, and Italian, he as yet knew nothing of the dead languages or literatures; however, seven years of study at the Collège de Conqueret not only repaired the defect, but stirred in him a wish, shared by his brethren of the rising Pleiad (q. v.), to regenerate his native tongue and poetry by forming them on classic models. Du Bellay, a cousin of his old master, put forth the programme of their design in the *Défense et Illustration de la Langue Française* (1549); R. was the first and boldest to fill it in—by copious borrowing from Greek and Latin, by the recoinage of current words, and lastly by drawing, where needful, on local dialects. One thing was wanting to crown his labours, a work which should, like Dante's, immortalise his diction and ideas. R. perceived the want, but failed to satisfy it with either *Odes* or *Amours* (1550), those studied, lifeless copies of antiquity, which Demogeot likens to old suits of armour, helm, hauberk, buckler, everything but the man within. But if Rabelais and Marot's followers satirised, kings, nobles, and scholars hailed them rapturously; master-spirits like L'Hospital, Scaliger, and De Thou viewed R. as the Phoenix of their day; no writer save Voltaire was ever the object of such idolatry. Tasso, coming to Paris in 1571, was overjoyed by his approval of the *Gerusalemme*. Charles IX. outvied his predecessors' bounties to the poet, who paid him back by furious anti-Calvinistic pamphlets and by *La Franciade* (1572), an epic fragment on the origin of the French nation. On Charles's death in 1574 R. retired to one of his many benefices, the Abbey of Croix-Val, but not to oblivion, Elizabeth sending him thither splendid jewels, and Mary Stuart, from her English prison, a salver valued at 2000 crowns. His later years were spent in the task of revision, often for the worse, and he died 27th December 1585. His poems, condemned by Malherbe and Boileau, lay long unread, awaiting their rehabilitation by the Romanticists (1828). The blind enthusiasm of the 'Cénacle' has also passed away, and calmer critics now value R. less for his graceful pedantry and borrowed lustre than for the debt his language owes to him. Selections of his works have been published by Sainte-Beuve (1828), La Croix (1840), and Becq le Fouquieres (1873), and a complete edition by Blanchemain (8 vols. 1857-58). See Colletet's *Vie de R.* prefixed to the *Œuvres inédites de R.* (Par. 1854), and

Demogeot's *Histoire de la Littérature Française* (13th ed. Par. 1873).

Bood (Old Eng. *roð*), a cross or crucifix generally, and specially the large crucifix flanked by figures of Our Lady and St. John, which in Catholic churches is placed at the entrance to the chancel, either on a mere beam (R.-beam) or on a gallery (R.-loft) surmounted by the Screen (q. v.).

Rood (Old Eng. *rod*), a measure of surface, equal to the fourth part of an acre, or forty square poles.

Roof (Old Eng. *hrōf*), the top covering of a building, to protect it from the weather and also to bind the walls together. It generally consists of a framework of wood which carries a covering of slates, lead, or other materials. Roofs are of varied forms. Usually they are formed of two or more sloping sides, but sometimes they are flat or dome-shaped; when flat they are termed 'platform' roofs. Among the nations of antiquity roofs were made flat, as they still are in the East at the present day. The Greeks introduced sloping roofs, the *pitch* or slope of the rafters being 12° to 16°. The Romans pitched their roofs at an angle ranging about 23° or 24°, and at later times in more northern latitudes the slope was greater. In Gothic architecture the pitch was 60°, or in other words, the rafters and the *span* (the width between supports) formed an equilateral triangle. In buildings of the Elizabethan age the pitch was still greater, the rafters being longer than the span. Later, the rafters were made three-fourths of the length of the span, and this was called the *true pitch*. A slope of 30° is now very common, and sometimes roofs are executed still lower. The simplest form of R. is that in which timbers are arranged in an inclined plane, all on one side, as in fig. 1; it is called a 'shed' or 'lean-to' R. A rectangular building is usually covered with two inclined planes abutting at their upper ends, and forming what is termed a 'pent' R. This form of R. has a tendency to drive the walls outwards, therefore a horizontal *tie beam* is introduced to which the feet of the rafters are mortised; and further, to prevent *sagging*, or sinking in the middle, the tie-beam is strapped to a *king-post* which depends from the apex, the rafters abutting against it. Such an assemblage of timbers forms a 'truss' (fig. 2). These trusses are placed at intervals of about 10 feet, and across them horizontally are placed timbers called *purlins*, which serve to support the common rafters. The latter are placed at closer intervals than the *principal* rafters, and to them is fastened the boarding which carries the slates or other covering. The trusses rest on *wall-plates*, pieces of timber laid along the walls to distribute the pressure equally; the feet of the common rafters rest against a *pole-plate* set into the tie-beam, and their heads abut on a *ridge-piece*. All these parts are shown in fig. 3,

Fig. 1.

Fig. 2.

Fig. 3.

which represents a king-post roof suitable for a span of 20 to 30 feet. TB is the tie-beam, PR the principal rafters, or *principals*, K the king-post, P the purlins, CR the common rafters, *p* the pole-plate, W the wall-plate, R the ridge, and SS are *struts*, introduced as an additional support to long rafters. Fig. 4 illustrates another common form of R. adapted for a wider span than the foregoing. It is called a *queen-post* R. The king-post is strapped to a *straining-beam* SB, which keeps apart the upper ends of the *queen-posts*, QQ, supporting the rafters. The 'Mansard R.', named from the inventor, is constructed on the principle of a queen-post R., but by employing two sets of rafters and giving the upper set, extending from the queen-posts to the ridge, a less slope than the lower, the height of the building is kept down, while as in fig. 4 a roomy apartment is obtained inside. The Mansard R. is sometimes called a 'curb' R., and, on account of its being very fashionable in France, a 'French' R. De Lorme, a celebrated French architect of the 16th c., invented a system of building arched roofs with short curved planks securely

joined together. It has been largely adopted for domed roofs on the Continent. The high-pitch open timber roofs of the Middle Ages are much admired for their beauty. In one

Fig. 4.

common form of Gothic R., short beams, called *hammer-beams*, project from the top of the walls, and carry queen-posts which support the principals, a tie, in the form of a *collar-beam*, being there introduced. The ridge and the collar-beam are connected by a king-post. Concave struts or ribs springing from corbels support the hammer-beams, and on these again rest other curved struts which meet under the centre of the collar-beam. The effect of a vaulted ceiling thus obtained is occasionally greatly enhanced by the introduction of carved figures, tracery, bosses, &c. Large spans are now usually covered with roofs constructed of malleable iron rods and bars, as may be seen in many railway stations.

Rook (*Corvus frugilegus*), a *Corvidæ* bird, belonging to the *Corvidæ* or crow family. It attains a length varying from 16 to 18 inches. Its colour is a deep, bluish black, and a distinctive mark is found in a patch of bare whitish skin on the forehead and base of the neck of the adult. The habits of the R. are well known. The bird is wary and active, and speedily familiarises itself with the scarecrows and other objects placed in fields with the view of terrifying it. It usually builds near man's dwellings, but is suspicious of every movement of its landlord, and at the first sound of the gun will leave its nest and hover about as if in alarm and distress. The idea that the R. is destructive to growing crops has been hotly combated by the opposite assertion that the bird is not usually a vegetable feeder, and that whatever injury may be done to the crops is fully compensated by the eradication of noxious insects and their larvae. The actual injury inflicted upon vegetation is thus held to be necessary for the capture and destruction of the larvae. The R. is known to attack the young of other birds. It has been seen to kill young partridges, and even to destroy the eggs of game birds. But on the whole it may be accounted rather the friend than the foe of farmers. White or piebald varieties of the R. are known. Occasionally the R. may be domesticated, or may even be taught to mimic sounds.

Law Regarding Rooks.—There is no right of property in rooks; the owner of a rookery having no ground of action against any one shooting the rooks from the land of another. But he may close his own land against the public; and should any one trespass, the proprietor may proceed against him by, in English law, *Injunction* (q. v.), in Scotch law, by *Interdict* (q. v.).

Rooke, Sir George. was born at Canterbury in 1650. He entered the navy as a volunteer, by regular stages became vice-admiral of the blue, and in the battle of La Hogue, 22d May 1692, led a night attack on the enemy's squadron, burning six French three-deckers and seven other ships of the line, with the loss of only ten men. He then became vice-admiral of the red, was knighted, and obtained a pension of £1000. During the reign of William he twice represented Portsmouth in Parliament. Upon declaration of the war of the Spanish Succession, he commanded a fleet sent to Cadiz, and before returning home attacked and pillaged the town of Vigo and seventeen ships of the Plate fleet. In July 1704 he joined with Sir Cloudesley Shovel and the Prince of Hessen before Gibraltar, and caused the Spanish garrison to surrender within a week. In August of the same year he forced a battle with a French fleet of 78 sail off Malaga; the French lost 3000 men and the English 2000. Party intrigue forced R. soon after to retire to his seat in Kent. He died January 24, 1708. See *Life and Glorious Actions of Sir George Rooke, Vice-Admiral of England* (Lond. 1707).

Boon, Albrecht Theodor Emil, Graf von, a celebrated Prussian general and military reformer, was born at the family seat of Pleusberg, near Kolberg in Pommern, 3d April 1803, entered the cadet school of Kulm in 1816, became lieutenant of infantry in 1821, studied at the Berlin Kriegsschule 1824-27, was appointed teacher of cadets in 1828, member of the general staff topographical survey in 1833, and teacher in the Berlin Kriegs-

schule in 1835. As chief of the staff of the Eighth Army Corps, he took part in quelling the revolt of Baden in 1849, and after rising step by step to the chief command of the 14th Division, was made Minister of War in 1859, an office which he held from 1861 in conjunction with that of Minister of Marine. During the struggle between the Government and the majority of the Diet (1861-66) he carried out his plan of army reorganisation in the face of strenuous opposition. After the war of 1866, which demonstrated his ability in organisation, he received the Cross of the Black Eagle, and after the French campaign of 1870-71 was rewarded with the rank of Graf. He resigned the office of Minister of Marine in 1871, and on the unexpected resignation by Bismarck of the presidency of the Cabinet after the triumph of passing the Districts Organisation Bill (1872), the office devolved on him as senior Minister of State. It is generally supposed that he merely held the premiership as a *locum tenens* till Bismarck was reinstated with increased authority and prestige, at the head of a larger Liberal majority, 11th November 1873. Since then, Graf von R. has lived in retirement, chiefly at his Potsdam estate of Gützergotz. He is the author of various works on military subjects, of which the principal are *Grundzüge der Erd-, Völker- und Staatenkunde* (3d ed. 3 vols. 1847-55), *Militär. Landbeschreibung von Europa* (1838), and *Anfangsgründe* (12th ed. 1868).

Roopur (Rūpar), a town in the district of Hoshiarpur, Punjab, British India, on the left bank of the river Sutlej, 1120 miles N.W. of Calcutta. It was the scene of the celebrated meeting between Lord W. Bentinck and Runjeet Singh in 1831, which has been called the 'Indian field of the cloth of gold.' After much military display on both sides, the Sikh ruler received a document guaranteeing to him the perpetual friendship of the British.

Roorkee (Rūrkl), a town in the district of Saharanpur, N.W. Provinces, British India, 112 miles N.E. of Delhi, on a ridge overlooking the Ganges Canal. Pop. (1872) 10,778. It is the headquarters of the Ganges Canal workshops, and has cantonments for 1000 men, chiefly sappers and miners, who mutinied in 1857. R. has an excellent meteorological observatory; an ironfoundry, established in 1852; and the Thomason civil engineering college, founded in 1847, and attended in 1873 by 157 students, European and native.

Root, in Algebra, is any quantity which, when substituted in a given equation for the variable quantity, renders that equation an identity. Thus in the equation $x^2 - 3ax + 2a^2$, a and $2a$ are roots, because when either is substituted for x , the equation becomes identically zero. This is more readily seen if the equation is written in the form $(x - a)(x - 2a) = 0$. The most general equation of the n th degree may be thrown into the form $(x - a_1)(x - a_2)(x - a_3) \dots (x - a_n) = 0$, when $a_1, a_2, a_3, \&c.$, which may be real or imaginary, are the roots of the equation. In the equation $x^n - a = 0$, there is, arithmetically, only one root, namely, the number which, multiplied by itself n times in succession, gives a . This number is called the n th root of a , and is written $\sqrt[n]{a}$. The square root of a quantity is commonly called the root, and its symbol is $\sqrt{}$. See EQUATIONS.

Root, in flowering plants, is the *descending axis* of the plant; it is that part which is the development of a *radicle*, and always bears at its apex a *root-cap*. The R. produces neither buds, leaves, nor flowers, has seldom if ever any distinct pith, the epidermis has no Stomata (q. v.), and it does not branch symmetrically. Its functions are—(1) to fix the plant in or to the soil, or other substance on which it grows. (2) To absorb nourishment from the soil, water, or air into which the fibres have penetrated (or from other plants in the case of parasites), and to transmit it rapidly to the stem. The absorption takes place through the young growing extremities of the fibres, and through a peculiar kind of hairs or absorbing organs which are formed at or near those growing extremities. The transmission to the stem is through the tissues of the R. itself. The nutriment absorbed consists chiefly of carbonic acid and nitrogen, or nitrogenous compounds dissolved in water. (3) In some cases roots secrete or exude small quantities of matter in a manner and with a purpose not satisfactorily ascertained.

Roots grow in length constantly and regularly at the extremity of their fibres, in proportion as they find the requisite nutriment.

They form no buds containing the germ of future branches, but their fibres proceed irregularly from any part of their surface without previous indication. The R. of exogens when perennial increase in thickness like stems by the addition of concentric layers, but these are usually much less distinctly marked, and in a large number of perennial exogens and most endogens the roots are annual, perishing at the close of the season, fresh adventitious roots springing from the stock when vegetation commences the following season.

Although roots proceed usually from the base of the stem or stock, they may also be produced from the base of any bud, especially if the bud lie along the ground, or is otherwise placed by nature or art in circumstances favourable for their development, or indeed occasionally from almost any part of the plant. They are then often distinguished as *adventitious*, but this term is applied by some to all the roots which are not in prolongation of the original radicle. Roots are *fibrous* when they consist chiefly of slender fibres; *tuberous* when either the main R. or its branches are thickened into one or more short, fleshy, or woody masses called *Tubers* (q. v.); *taproots* when the main R. descends perpendicularly into the earth, emitting only very small fibrous branches. The stock of a herbaceous perennial, or the lower part of the stem of an annual or perennial, or the lowest branches of a plant, are sometimes underground, and assume the appearance of a R. They then take the name of *rhizome*. The rhizome may always be distinguished from the true R. by the presence or production of one or more buds, or leaves, or scales (*Bentham*). The roots in Cryptogamia are always adventitious, and are termed *heterorhizal* (Gr. *heteros*, 'dissimilar'), the rootlets proceeding from various parts of a spore during germination.

Root-Mildew, or Root Fungus, is a name given by horticulturists to a garden pest arising from the *mycelia of fungi* developing amidst the roots of plants, causing the death of such roots, followed by the stoppage of growth and visible sickening of the plant, and ultimately causing its death. This plague probably originates from the use of unsuitable manures; e.g., it has shown itself in a bad form where the raspings and parings of horses' hoofs from the shoeing-smith's shop had been mixed with the manure applied to a vine border.

Root Parasites comprise the section of Parasitic Plants (q. v.) which are attached by suckers to the roots of other plants, and draw nourishment therefrom. The broomrape and toothwort are examples.

Roots, the primitive elements of language, at which analysis must stop, but to which all words are ultimately reducible, have mostly a material meaning so comprehensive as to be capable of application to a variety of objects. Thus from the root *mar*, 'to crush,' come words denoting mill, death, sea, milk, &c., an economy which helps us to understand how Hebrew manages with only 500 R. (Renan), Gothic with 600 (Benloew), and Sanskrit with 1706 (Benfey). Till recently it was believed that all R. in all languages were necessarily monosyllabic; but this theory, founded on a one-sided study of the Aryan family, is now exploded by the recovery of Accadian from the cuneiform inscriptions, where dissyllabic R. like *dugud*, 'heavy,' occur, although less frequently than monosyllables, and also by Bleek's investigations into the Ba-ntu of Southern Africa, in which they appear to be rather the rule than the exception. There are, moreover, even in Aryan, a certain number of so-called 'demonstrative' R., the basis of the pronouns, in which it is impossible to discover any underlying abstract concept, and Semitic R. are as distinctly nominal in their character as those of Aryan are verbal. See LANGUAGE and PHILOLOGY, COMPARATIVE.

Root-Stock, Rhizo'ma, or Rhizome, is a prostrate rooting stem, progressively throwing up leaves. The name is applied among ferns to the creeping stem, which may be either superficial or subterranean. See ROOT.

Rope. A R. is a strong heavy cord, usually made of common hemp, Manila hemp, sunn, esparto, or other similar vegetable fibre, or of iron, steel, or other metallic wire. Hemp, Manila, and iron wire are by far the most frequently employed materials. A R. is composed of a certain number of yarns or threads, which are first spun or twisted into strands, and the finished R. goes under special names, according to the number and arrangement

of the strands of which it is composed. A *hawser-laid R.*—the commonest form—is composed of three strands twisted together; a *cable-laid R.* consists of three such hawser-laid ropes twisted into one, and ropes of this construction, when they are of less than 10-inch girth are termed *cables*. A *shroud-laid R.* is composed of four strands, three outer strands being twisted around another employed as a core or heart. *Flat ropes* usually consist of a series of *hawser-lays* placed side by side and bound together by sewing in a zigzag direction. The maximum of resistance to tensile strain in fibres or wire is obtained when the individual fibres are laid parallel to each other, under which circumstances the strength of the whole is found by adding together the strength of each separate fibre. Therefore, for the sake of strength alone, the less of tension or twisting to which the fibres are subjected the better will be the result, and the twisting is only serviceable to keep a compact whole, and to give the necessary amount of friction to prevent the fibres from slipping away from each other. The building up of the R. of distinct small yarns and separate strands serves to keep a greater parallelism in the fibres than could be otherwise secured. The manufacture of ropes was formerly entirely conducted under long narrow sheds called R. walks, the entire length of which extended to about a quarter of a mile, the twisting of the yarns and strands having been almost entirely a matter of manual labour. A machine for spinning ropes, termed the *cordelier*, was invented in 1792 by Cartwright, the principle of which was subsequently developed and improved by many hands; but still manual labour and the R.-walk continued to prevail till very recent times. Within the last two or three years R.-making machinery, invented by Mr. Good in the United States, and now manufactured by Messrs. Lawson & Sons, Leeds, has been very extensively adopted. Good's automatic spinner, which is the essential machine, is a small, exceedingly compact, and wonderfully adjusted piece of mechanism for preparing yarn or cord of any particular dimensions. If the feed of fibre is too great, the apparatus accelerates its motion proportionately, and when too little fibre approaches the trumpet mouth the motion is similarly retarded, and again when the feed ceases, immediately the machine is thrown out of gear. At the same time the apparatus puts a gloss or surface on the yarn which cannot be approached by other means. Iron, steel, and other metallic ropes are twisted from huge bobbins, which revolve horizontally on a framework, the strands rising from these, and being twisted in a neck at the apex of the machine. Steel ropes, which possess great strength and flexibility, are now extensively employed.

Ror'qual (*Physalus*), a genus of *Cetacea*, or whales, belonging to the family *Balenida*, or that of the Whalebone whales, in which teeth are wanting; the palate bearing plates of *balen* or *whalebone*, while the nostrils or *blowholes* are placed on the top of the head. These whales include the largest cetaceans, specimens having been captured 120 feet in length. The R. is not in request amongst whalers, as the whalebone and oil are present in small quantity, and the habits of the animal are fierce, and render its capture difficult and even dangerous. The R. is included amongst the so-called 'finner' whales, which possess a small dorsal fin—a structure absent in the whalebone or Greenland whale (*Balena mysticetus*). The name 'Piked' whale is also given to the R., from the comparative sharpness of the muzzle as compared with that of the Greenland whale. The skin is furrowed, and hence the term 'Furrowed' whale, given to the R. The best-known species are the P. or *Balenoptera Rorops* of the N. Seas, and the *B. Australis* of the W. Ocean. The species known as the *B. rostrata* or *B. musculus* is now regarded as the young of the *B. Rorops*. The R. is frequently stranded on British coasts while pursuing shoals of herrings. The term 'R.' means a 'whale with folds in the skin,' and is derived from the Norwegianian.

Ro'sa, Salva'tor, painter, poet, and musician, was born at Renella, near Naples, 20th June 1615. He received a liberal education, and despite the opposition of his father, who intended him for the Church, he became a painter, and after studying under Francanzano and Ribera, proceeded to Rome in 1635. Here he drugged in obscurity for some time, but catching fever in his lonely rambles in the Campagna, was forced to return to Naples, only to find his family dispersed and the profession ready to taunt him with his failure. He found, however, a patron in the Cardinal Brancacci, and his fame was at last established

by the exhibition of his 'Prometheus' in the Pantheon. In 1639 he returned to Rome, where he rapidly acquired favour and fortune, and where henceforth he resided, except during short intervals spent at Naples, Viterbo, Florence, &c. His six satires, on music, poetry, painting, war, Babylon, and envy, written at Volterra, made him many enemies, and were extensively circulated before they were first printed in 1719. R. took part in the Neapolitan risings under Masaniello (who sat to him for a portrait), and joined the Compagnia della Morte (1645). Restless and impulsive, he spent his later years in intense devotion to his art, broken in upon by fits of gloom and inactivity. He died at Rome, 15th March 1673, leaving a considerable property. His works almost invariably represent nature in a portentous or angry mood, and their spirit is in strict harmony with the artist's character. He painted many striking historical and *genre* pieces, but his chief works are landscapes—wild mountain masses and sombre woods, surf-beaten coasts and treacherous defiles—in which the prevailing sentiment is loneliness, desolation, or fear. R. played on various musical instruments, and, as a composer, was 'superior in melody to most of the masters of his time.' He also excelled as an engraver, a dramatist, a poetical satirist, a comic actor, and an improvisatore. See, besides the works of Passeri and Dominici, the biographies by Baldinucci (new ed. Ven. 1830) and by Lady Morgan (new ed. Lond. 1855).

Rosa'cea, or **Ac'ne Rosa'cea**, known also as *Gutta Rosea*, and popularly, though inaccurately, as *Grog-blossom*, is a disease which usually appears on the nose, which is often considerably enlarged by the morbid action. R. sometimes extends to the cheeks, forehead, and chin, and may cover the entire face. It is a disease of adult life, and is more frequent in the female than in the male. It may depend on a disordered state of cutaneous innervation, or direct congestion of the integument, or torpidity of the capillary circulation and obstruction. R. may occur at puberty, and at the critical period of life in females; but it is more frequently the result of exposure of the face to extremes of temperature, of excesses in diet or stimulating drinks.

The general treatment of R. must be adapted to the cause. The diet should be moderate and nutritious, and all stimulants should be avoided. Laxatives, antacids, and tonics may be administered. In the acute or inflammatory stage the pimples may be punctured, and bleeding encouraged by warm fomentations or poultices, or emollient lotions may be applied. In the chronic or indurated stage, friction and gentle stimulation are useful, while in the severer forms iodide of sulphur ointment may be applied, or the follicles may be pressed out and a lotion of dilute acetic acid applied.

Rosa'ceæ, a large and important natural order of herbs, shrubs, and trees, with usually alternate stipulate leaves, and regular, often showy flowers. The petals and calyx lobes are four or five; the stamens usually indefinite, inserted on the calyx tube or disc; the fruit various—a pome, or of one or many drupes, achenes, or follicles; rarely a berry or capsule. The order is botanically distinguished from *Leguminosæ* by the superior fifth lobe of its calyx; in that order it is anterior. R. numbers upwards of 70 genera, and more than 1000 broadly defined species, and is represented in all quarters of the globe. It is divided into nine tribes or sub-orders. In the *Potentilleæ* and *Roseæ* the properties are astringent, and in *Prunææ* and *Torneææ*, hydrocyanic and malic acids are secreted. Many of the plants of the order yield edible fruits, others constitute some of the choicest ornaments of the garden, and the timber of others is valuable.

Rosario, a town in the Argentine Republic, 170 miles W. of Buenos Ayres, on the right bank of the river Paraná (q. v.). Being the entrepôt for a large region, the trade of R. is very extensive: 3189 vessels, with an aggregate tonnage of 321,778, entered and cleared at the port in 1876. The chief exports are wool, hides, bones, dried beef, maize, and wheat, together with copper and silver from the mines of Catamarca and San Luis. R. is the centre of railway lines which had a combined length of 748 miles in 1876, and one of which will eventually connect it with Valparaiso on the Pacific. Pop. (1877) 25,000.

Rosary, a number of beads strung together, used in devotional exercises by Hindus, Buddhists, Mohammedans, and Roman Catholics. The beads are of various materials, stone,

coral, amber, wood, seeds, and ivory being employed. The R. probably had its origin in India, where it has been used for upwards of 2000 years. The R. of the Hindus and the Buddhists consists of 108 beads, which when used by Vaishnavas and Buddhists, are always made of the smooth wood or seeds of the Toolasee plant (*Ocimum sanctum*). The beads of the Saivas consist of the rugged berries of the Rudracha tree (*Elacarpus tuberculatus*). The Mohammedan R., or *tusbeeh*, is made up of 100 beads in honour of the same number of names of the Deity. The Lady Psalter of the Roman Catholics contains three groups of fifty-five beads each, or fifteen decades, in honour of the five glorious, five joyous, and five sorrowful events of Our Lord's life, death, and resurrection.

Rosary of the Blessed Virgin Mary is a form of prayer used by Roman Catholics, especially by families, as a daily evening prayer. The devotion of the Rosary, which consists of a series of fifteen prayers, with repetitions throughout of Pater Noster, Ave Maria, and Gloria Patri, was introduced by St. Dominic (q. v.) about 1206. It is divided into three parts—the Joyful, the Sorrowful, and the Glorious Mysteries, each of which contains five subdivisions. Each subdivision contains a statement of a mystery connected with the life of our Saviour, or his blessed Mother, to be meditated on, and a prayer for the special grace appropriate to it; besides a Pater Noster at the beginning, a Gloria Patri at the end, and ten Ave Marias, from which last each division gets the name of a decade. At the end of each of the three parts, or each five decades, the *Salve Regina* is said. From containing 150 Ave Marias, the number of the Psalms, the R. has been called the Psalter of Mary. The Living R. is an association of fifteen persons who divide amongst them the fifteen mysteries of the R. Each member recites one mystery or decade daily, so that the entire R. is gone through every day. The association was instituted at Lyons by Sister Maria Jericott, and confirmed by a brief of Pope Gregory XVI. in 1832.

Ros'as, Juan Manuel Ortiz de, the founder of the Argentine Confederation, was born of an old Asturian family at Buenos Ayres, March 30, 1793. He spent a wild, irregular youth among the 'Guachos' of the Pampas, and acquired great influence by his bold exploits on the Indian frontier. Entering the army of Buenos Ayres, he was made a commander in the Pampas, and in 1829 overthrew Lavalle, in whose place he became captain-general, proclaiming 'Federal' principles. In concert with the governor of the interior provinces he established the Argentine Confederation (1831), retaining in his own hands the direction of foreign relations, and visiting political opponents with the utmost severity. He was chosen president in 1835, and maintained his position for eighteen years, partly by a restless energy which had no mercy for his enemies, the 'savage Unitarians,' and partly by popular appeals to 'the holy principle of federation.' He cruelly suppressed four great risings of the Argentine Liberals; struggled fiercely throughout five years with Brazil for the possession of Paraguay; and for nine years besieged Montevideo, the stronghold of the 'Unitarians.' At last his chief officer, Urquiza, went over to the Liberal party, defeated R. at Monte Caseros, and succeeded him as president in February 1852. R. escaped in disguise, reached England, and settled at Southampton, where he died, 14th March 1877.

Ros'cius Quin'tus, the most famous of Roman comic actors, was born at Solanum, a town of the Sabine territory near Lanuvium, and flourished in the 1st c. B.C. He was said to have been found, when an infant, in the folds of a serpent, a presage, it was thought, of that extraordinary skill which gained him the favour of the noblest Romans. R. enjoyed the friendship of Cicero, who, when a young man, received instruction from him in elocution, and in a later time used often to compete with his eloquence against the actor's gesticulation in expressing a thought. In 68 B. C. Fannius Chaerea sued R. for 50,000 sesterces, and Cicero defended him in an oration which we still possess. R. died in 62, leaving an immense fortune, and a name which has become proverbial as synonymous with perfection in any profession.

Roscoe, William, the historian of the Italian Renaissance, was the son of a respectable tavern-keeper and market-gardener at Mount Pleasant, Liverpool, where he was born, March 8, 1753. In his sixteenth year he was articled to a Liverpool attorney, and in 1774 was admitted an attorney of the Court of King's Bench.

Though he practised assiduously, he yet found leisure to acquire a knowledge of Greek, Latin, Italian, and French. In 1777 he published a collection of poems, one of which being a protest against the slave-trade, and the precursor of several eloquent pamphlets on the same subject. A zealous advocate of the French Revolution, he taxed Burke with apostasy in his *Strictures on that statesman's Two Letters Addressed to a Member of the Present Parliament*. In 1799 appeared the *Life of Lorenzo de Medici, called the Magnificent*, a work which at once established his reputation as a solid historian and an agreeable writer. The charge brought against R. by Sismondi, of his having in this work veiled the tyranny of the Medici, and the accusation by other critics of his having defended the part taken by Pope Sixtus IV. in the Pazzi conspiracy, which led to the murder of Giuliano, Lorenzo's brother, received an able reply in the *Illustrations, Historical and Critical, of the Life of Lorenzo de Medici* (1822). Meantime the work passed through several editions, and was translated into various European languages. R.'s second great historical work, *The History of the Life and Pontificate of Leo X.* (4 vols. folio, 1805), distinguished equally by the fine literary qualities of the first, drew upon its author the censure of various critics, on the alleged ground of undue partiality for his subject, and hostility to the reformers who struggled against the absolutism of papal Rome. The two works give a luminous and accurate account of the revival of letters, and form an admirable link between Gibbon's *Decline and Fall* and Robertson's *Charles V.* In 1806 R. was returned to Parliament for Liverpool in the Whig interest, but exciting violent opposition by his speeches on the Catholic disabilities, he withdrew at the time of the dissolution, and resolutely declined to appear again as a candidate. Still, however, taking a warm interest in passing events, he issued several pamphlets on the topics of the day. Pecuniary embarrassments clouded his declining years. A banking firm, of which he was a partner, became bankrupt in 1816, and he had to part with his valuable library and collection of pictures. But his intellectual ardour remained undiminished, and in his latter years he aided in founding the Royal Institution of Liverpool, edited an edition of Pope in 10 vols., and acquired a superior knowledge of botany. In 1827 he received the gold medal of the Royal Society of Literature. He died at Liverpool, June 30, 1831, leaving the sketch and materials for a projected history of art and literature.—His son, **Henry R.** (born 1799, died 1836), who rose to distinction at the bar, is the author of *Lives of Eminent British Lawyers* (1830), and of a *Life of W. R.* (2 vols. 1836).—**Henry Enfield R., R.S.E.**, son of the preceding, and a celebrated chemist, was born at London, January 7, 1833. He graduated at University College, London, in 1852, and after completing his chemistry studies at Heidelberg, became professor of chemistry in Owens College, Manchester, in 1857. He has published numerous papers in the Philosophical Transactions and other scientific journals, and in 1873 received the Royal Medal of the Royal Society for his chemical researches, especially for investigations into the chemical action of light and into the compounds of vanadium. He is author of *Lessons in Elementary Chemistry* (1866, new ed. 1875); *Lectures on Spectrum Analysis* (1869, 3d ed. 1873), and in conjunction with Schverlemmer a *Treatise on Chemistry* (2 vols. 1877-78). He has also written the *Chemistry Primer* in Macmillan's Science Primer Series, of which he is joint-editor with Professors Huxley and Balfour Stewart.

Roscomm'on, an inland county of Ireland, separated on the E. from Longford and W. Meath by the Shannon, on the W. from Galway and Mayo by the Shannon and its affluent the Suck, and having on the N., Sligo and Leitrim. Area, 607,691 statute acres, of which 469,400 are arable and 101,244 uncultivated. Pop. (1871) 140,670. The surface is mostly level and undulating, highest in the N., where the Curlew Hills rise above 800 feet, and the Braulieve Mountains and Slieve Curkagh to 1000 feet. The chief rivers are the Shannon and Suck, which together form about two-thirds of the whole boundary-line of the county. The lakes, which are numerous and beautiful, are either expansions of the Shannon or communicate with it. The principal are Loughs Allen, Corry, Tap, Ree, Skee, Gara, and Key. In its geological formation the county is a continuation of the central limestone district of Ireland. In the N. are coal-measures. The soil is fertile, but agriculture is in a back-

ward state. There is excellent pasture for sheep throughout R. In 1876 there were 8097 horses, 8567 asses, 108,520 cattle, 194,725 sheep, 35,687 pigs, 11,694 goats, and 475,032 poultry. There are some manufactures of brick and earthenware. The chief towns are R. (q. v.), Boyle, Elphin, Castleroa, and Strokestown. The county returns two members to Parliament.

Roscomm'on (Ir. Gael, 'the wood of St. Coman'), chief town of the preceding county, near the centre of the county, 96 miles W. by N. of Dublin. It dates from the 13th c., when an abbey was founded here by O'Connor, King of Connaught, and a few years later a castle by Sir Robert de Ufford. It returned previous to the Union two members to the Irish Parliament. R. has a considerable corn market. Pop. (1871) 2722, of whom 300 were Protestants.

Roscrea (Ir. Gael, 'Cre's wood'), a town of Tipperary, Ireland, 94 miles S.W. by W. of Dublin, on a feeder of the Lower Brosna river, is of great antiquity, having arisen round a monastery built in 620. R. has a small manufacture of coarse woollen cloths, and a great deal of agricultural produce is sold at the weekly markets. It contains a parish church built in 1812; Wesleyan, Primitive Methodist, and Quaker places of worship, a very handsome Roman Catholic church, a national school, and others partially endowed, a savings-bank, court-house, market-house, fever-hospital, dispensary, union workhouse, bridewell, infantry barracks, Ormond Castle, now used as a military storehouse, and an ancient round tower, 80 feet high. Fairs are held seven times a year. Pop. (1871) 3725.

Rose. See ERYTHREAS.

Rose (Lat. *rosa*, Gr. *rodon*, 'red,' Sansk. *rohida*, 'red') is the type genus of *Rosaceæ*, and consists of erect, scrambling, or climbing shrubs, more or less prickly, with imparipinnate leaves, serrate leaflets, and stipules more or less adnate to the petiole. The flowers are terminal; and are solitary, corymbose, or paniculate. The calyx-tube is persistent, globose, urceolate, or ovoid; the mouth is contracted, and the limb divided into five foliaceous segments. The petals are five, rarely four; the stamens are numerous, inserted on the edge of disc, at the mouth of the calyx-tube, the styles protruding from the tube, and sometimes united. When in fruit, the carpels are dry, hairy, one-sided achenes, enclosed in the more or less succulent calyx-tube, the whole forming a dry or pulpy red or black 'Hip' (q. v.). The genus is predominant in the temperate regions of the northern hemisphere—much less so in America than in the Old World—extending S. into India, Abyssinia, and Mexico. The number of species is very differently estimated by different botanists.

The R. is a general favourite; and whether we look to the position which it occupies in the poetry of almost all lands, to its historical, literary, and legendary associations, to its universal popularity as a garden flower, to its delicious scent, or to the attention it has attracted amongst horticulturists, we find it pre-eminent among flowers. It is mentioned by Homer and Anacreon—by the former in his hymn to Ceres, by the latter in many of his odes. Theophrastus specifies four kinds, and Pliny gives a fair description of the shrub, and enumerates eleven kinds, which, he says, were well known to the Romans. He also speaks of the *rusaria*, or places set apart for the cultivation of R.-trees, the most celebrated of these being at Pæstum. The R. was used at festivals and sacred ceremonies; and as an article of luxury at banquets (cf. *Horace*, lib. i., ode xxxviii.). Suetonius relates that Nero spent upwards of £30,000 at one supper in the purchase of roses, and a like extravagance is recorded of Cleopatra (Athenæus, *Dipsosoph.*, lib. iv. c. ii.).

Five well-marked groups of *Rosæ* are indigenous to Britain, divided into about 70 recognised sub-species or varieties. Of the species of R. generally cultivated the following are some of the most important. The Cabbage R. and Moss R. (*R. centifolia*), a native of the Caucasus and seemingly of other parts of the Orient, is excelled by no other species in beauty and fragrance. The Damask R. (*R. damascena*), a supposed native of Syria, is much cultivated for ornament, and is, with the above, the source of the attar of roses. The French or Dutch R. (*R. gallica*) is indigenous in S. and central Europe and Asia Minor; the intensely coloured buds of this species are particularly chosen for drying. The India or China R. (*R. Indica*), a native of China, but brought early into India, is a glabrous evergreen of the *canina* section, with large double or half-double (rarely

single) white, yellow, pink, red, or purple flowers, in long slender pedicels. The scent is powerful, though not so delicate as in the *Gallica* group above mentioned. From the present species the large host of 'hybrid perpetuals' are mostly derived, and to it belong the Tea R. (*R. fragrans*), with very fragrant yellow flowers, and *R. semperflorens*, with dark-red flowers, and numerous other varieties. The Noisette R. is a cross of this species and *R. moschata*. Lady Banks' R. (*R. Banksia*) is a climbing species from China and Japan, with rarely more than three or five leaflets on the leaves, and corymbs of small white or yellow flowers. The yellow R. (*R. lutea*) is another yellow-flowered species, a native of the Himalaya and neighbouring territory, and now naturalised in central and S. Europe; the smell is disagreeable. The Musk R. (*R. moschata*), in its wild state in India, &c., forms masses of thorny, scrambling scrub, and climbs to the top of lofty trees, hanging down therefrom in elegant festoons. Its white flowers, in large compound corymbs, have a strong and delightful fragrance, and the plant has been cultivated in Britain for 300 years. The evergreen R. (*R. sempervirens*), ranging from S. Europe through Southern Asia to Japan, is one of the most desirable roses for covering walls, fences, and similar structures. The Prairie R. (*R. setigera*), a native of the Western and middle United States, is one of the best ornamental midsummer hardy plants, with profuse, dense corymbs of single, deep-rose flowers. Of native British species, the burnet-leaved or Scotch R. (*R. spinosissima*) has furnished numerous varieties now in cultivation; the sweet-briar (*R. rubiginosa*), which is truly wild in the chalk hills of the S. of England, is grown in most gardens; and the field R. (*R. arvensis*) is frequently planted and trained to cover trellises and walls. The strong straight shoots of the common dog R. (*R. canina*) are used as stocks for budding the choice varieties of garden R. upon—thus making them into standards. Homer speaks (*Il.* xxiii. 186) of rich unguents and oils prepared from the R. The modern preparations obtained from it are *R.-water*, used as an agreeable perfume; *R. vinegar*; a conserve of the petals employed as a basis for pills, and a feeble astringent; a *syrup of roses*, used for flavouring and colouring purposes; a *conserve of the fruit* (see HIP); and the celebrated Otto or Attar of Roses (q.v.).

The so-called Rock R. is *Helianthemum* (see CISTUS); the Christmas R. is *Helleborus niger* (see HELLEBORE); the Corn R. is *Papaver Rhæas* (see POPPY); the Guelder R. is *Viburnum Opulus* (q.v.). See Hole's *Book about Roses* (5th ed. Blackwood, 1874).

Rose, in heraldry, is sometimes represented with five leaves, but usually with ten, of which five are placed within or upon the other five. The R. is without a stalk, unless that be named in the blazon. It is not blazoned proper, being tintured sometimes *gules* (Lancastrian), sometimes *argent* (Yorkist). When it is *barbed and seeded* proper, the barbs are green and the seeds gold. As a mark of cadency, the R. distinguishes the seventh son. The badges of the Stuart kings of England were a *thistle*, and a *R. and thistle dimidiated and crowned*, and of Anne, a *R. branch and a thistle growing from one stalk and crowned*. From the time of Anne the personal badges of English sovereigns have gone out of use, and the *R., thistle, and shamrock*, the imperial crown badges of England, Scotland, and Ireland, have been permanently placed in the Royal Arms.

Rose-Aca'cia. See ROBINIA.

Rose-Apple. See EUGENIA.

Rose-Beetle, or Rose-Bug, name applied to several insects belonging to the order *Coleoptera*. The *Cetonia aurata* is the British R.-B. In this genus the jaws are feebly developed. The species mentioned attains a length of an inch, and is green above and red beneath. It infests the rose in the adult states, its larvæ being found in decaying timber, &c. The R.-bug of N. America is the *Macrodactylus subspinosus*, and is also named the 'R.-chafer.' It is of a brown colour, and has slender legs and claws. This beetle injures the rose leaves. The eggs are deposited beneath the soil, and the larvæ appear in autumn. The pupa is developed in the succeeding May, and is of a yellowish-white colour.

Rose-Engine Lathe. See TURNING.

Rose'mary (*Rosmarinus*, 'sea spray,' from its usually growing on the sea-coast, and its odour) is a genus of *Labiata*, consisting of a single species, the common R. (*R. officinalis*), a bush

native of the countries around the Mediterranean. The leaves are evergreen, linear in shape, with a white coating on the under side; the flowers are few, of a dull leaden-blue or white colour, and arranged in short, axillary racemes. The principal value of R. is as a perfume, and owing to its pleasant fragrance it has been used from time immemorial. In olden times it also served for making garlands, and was considered useful in relieving headache and stimulating the flagging mental powers. It was also recognised as a token of remembrance at funerals (*Romeo and Juliet*, act iv., scene 4). The aromatic oil which is distilled from the flowering tops is given medicinally for hysteria, and a lotion and wash is applied in cases of baldness to promote the growth of the hair.

Ro'sen, Friedrich August, an able Orientalist, born at Hannover, 2d September 1805, studied Semitic languages and Sanskrit (1822-27) at Göttingen, Leipsic, Berlin, and Paris, and was the first professor of Oriental languages in the London University (1827-31). In the latter year he resigned this post, and on the 12th September, 1837, died at London. R. wrote *Radices Sanscriticæ* (Beil. 1827), and edited *The Algebra of Muhammed-ben-Musa* (Lond. 1831), *Haughton's Dictionary, Bengali, Sanskrit, and English* (ib. 1835), *Colebrooke's Miscellaneous Essays* (2 vols. ib. 1837), and *Rigveda Samhita* (Lib. I., Sansk. et Lat. ib. 1838), the last being published by the Asiatic Society, of which R. was secretary. A *Catalogus Codicum Manuscriptorum Syriacorum et Caramanicorum in Museo Britannico* by R. appeared (Lond. 1839) after his death.—**Georg B.**, brother of the above, born at Detmold, 24th September 1820, is the author of *Rudimenta Persica* (Leip. 1843), *Ueber die Sprache der Lazen* (Lemgo, 1844), *Ossetische Grammatik* (ib. 1846), and *Geschichte der Turkei von 1826 bis 1856* (2 vols. Leip. 1866-67).

Ro'senau, a town of Hungary, on the river Sajo, an affluent of the Theiss, 112 miles N.N.W. of Pesth. It carries on linen-bleaching, pottery, the manufacture of wax-tapers and leather, besides a trade in honey and wax. Near the town are mines of iron, lead, copper, and antimony, and also medicinal springs, Pop. (1869) 5053.

Ro'senmüller, Johann Georg, born 18th December 1736 at Unnerstadt, near Hildburghausen, became preacher at Konigsberg in 1772. In 1773 he was elected unexpectedly to a chair of theology at Erlangen, where in 1775 he got his doctor's degree. In 1783 he removed to Geissen for his health. There he acted as First Professor of Theology till he was elected in 1785 chief pastor of the church of St. Thomas, and Professor of Theology at Leipzig, where he died, 14th March 1815. R.'s preaching was full of unction, and he also did a great deal for the primary schools. His chief writings are *Morgen und Abend-nachten* (7th ed. Leip. 1820); *Betrachtungen über die vornehmsten Wahrheiten der Religion auf alle Tage des Jahres* (4 vols. Leip. 1801); *Predigten über auserlesene Stellen der Heiligen Schrift* (3 vols. Leip. 1811-13); *Auserlesenes Beicht- und Communionbuch* (12th ed. Nurnb. 1827); *Pastoralianweisung* (Leip. 1798); *Anleitung für angehende Geistliche* (Leip. 1792); *Beiträge zur Homiletik* (Leip. 1814); *Scholia in Novum Testamentum* (6 vols. 6th ed. by his son, L. F. K. R., Leip. 1815-31); *Historia Interpretationis Librorum Sacrorum in Ecclesia Christiana* (5 vols. Leip. 1795-1814); his *Handbuch eines allgemein. fasslichen Unterrichts in der Christlichen Glaubens- und Sittenlehre* was published posthumously (2 vols. Leip. 1818-19).—**Ernst Friedrich Karl B.**, eldest son of the preceding, famous as an Orientalist and Old Testament critic, was born at Hessberg near Hildburghausen, 10th December 1768. He studied at Leipzig, where in 1795 he became extraordinary, and in 1813 ordinary, Professor of Oriental Literature. He died 17th September 1835. R.'s great work was the *Scholia in Vetus Testamentum* (23 vols. Leip. 1788-1835), comprehensive, erudite, and still a valuable book of reference. He published also an abridged edition of this work in 5 vols. (Leip. 1828-35). His principal other works are the *Handbuch für die Literatur der Biblischen Kritik und Exegese* (4 vols. Gott. 1797-1800); *Das alte und neue Morgenland, oder Erläuterungen der Heil. Schrift* (6 vols. Leip. 1818-20); *Handbuch der Biblischen Alterthumskunde* (4 vols. Leip. 1823-31); *Institutiones ad Fundamenta Linguae Arabica* (Leip. 1818), founded on De Sacy; and *Analecta Arabica* (2 vols. Leip. 1825-26).—**Johann Christian B.**, the famous anatomist, was a younger brother of the preceding. He was born at Hessberg

in 1771, and in 1804 became ordinary professor of anatomy and surgery at Leipzig. He died 29th February 1850. His principal works are *Beiträge zur Zergliederungskunst* (2 vols. Leip. 1800); *Chirurgisch-anatom. Abbildungen für Ärzte und Wundärzte* (3 vols. Weimar, 1804-12); and *Handbuch der Anatomie* (Leip. 1808, 5th ed. by Weber, Leip. 1834).

Rose's Noble (Lat. *rosatus nobilis*, Fr. *noble à la rose*), an English gold coin, worth about 19s. 6d., first struck by Edward III., and so named from the rose figured on each side. The obverse presents a ship (with roses figured on its side), in which sits the king with sword and shield; the reverse, the eight-leaved rose and the legend *IHS Autem Transiens Per Medium Illorum Ibat*, probably referring to the king's disputes with the Holy See. This obscure inscription led to the R.-N. being held as an amulet against witchcraft and a protection against dangers on sea. A similar coin (the Rose-Rial), bearing on the reverse a rose supporting three lilies, was struck by Henry VII. and Henry VIII.

Rose of Jericho is a curious cruciferous plant named *Anastatica Hierochuntina*—the sole species of the genus. It grows in the sandy deserts of Syria, Arabia, and N. Africa, and is remarkable for the hygroscopic property of the old, withered annual stems. When in flower the branches spread rigidly, but as the seed ripens, the leaves begin to wither and drop off, the branches curl inwards, and the plant becomes coiled up so as to resemble a small ball. In this state it is loosened from the soil, and is drifted about with the sand over the arid plains. Should rain fall, or should it be blown into water, the branches expand, the pods open, the seeds fall out, and it is a remarkable fact—only recently discovered—that in the short space of twenty hours the seeds germinate and root. The plant retains its hygroscopic susceptibility for years.

Rose'ola, or **Rose-Rash**, sometimes called false measles, is a common skin disease characterised by febrile symptoms, and small irregular red patches of the skin distributed over more or less of the surface of the body, and by redness of the fauces. The eruption is usually accompanied by itching, prickling, or tingling of the skin, and the disappearance of the eruption is not followed by desquamation of the epidermis, one of the natural sequelæ of scarlatina and measles. One attack affords no immunity from a second. There are several varieties of R. The chief are *R. infantilis*, or *false measles* in children; *R. astiva*, or *false measles* in the adult; *R. autumnalis*, peculiar to children; *R. annulata*, appearing first as red-coloured spots, increasing into rings of variable size; *R. variolosa* frequently accompanying the eruptive fever of inoculated small-pox; *R. vaccina* frequently following the development of the vaccine vesicle; *R. rheumatica* appearing in spots and patches upon different parts of the body in persons affected with rheumatism and gout; and *R. cholericæ* described by Rayer, who observed it during the prevalence of cholera in Paris in 1832. R. in infants may be caused by teething or intestinal irritation; in adults by exposure to cold when heated; drinking cold water when heated; indigestion; gastric and intestinal irritation; and disordered menstruation. R. is a slight affection, and may be treated by laxatives, diluents, and salines, followed by tonics combined with mineral acids.

Rose Quartz, a beautiful rose-red or pink variety of quartz, largely used as an ornamental stone. Beautiful specimens come from Ratnapura in Ceylon; and it is also found in Aberdeenshire, the Shetlands, near Belfast, and in various parts of the continent. The colour is due to the presence of manganese.

Roses, The War of the, was a civil disturbance which desolated England for thirty years—from 1455 to 1485. The war was caused by the accession to the English throne of the Duke of Lancaster, Henry IV., instead of the presumptive heir, the Duke of York. The York faction chose a white rose for emblem, and the Lancastrians a red. The quarrel raged with greatest violence during the reigns of Henry VI., Edward IV., and Richard III. The first battle was fought at St. Alban's, May 22, 1455; the last at Bosworth, August 22, 1485. The union of the Roses was accomplished by the marriage of Henry VII. with Elizabeth, daughter of Edward IV., in 1486.

Rosett's (Arab. *Raschid*, 'headship'), a town in Egypt, on the W. bank of the ancient Bolbitic branch of the Nile, 4 miles from

its mouth, and 43 miles N.E. of Alexandria. It was built by one of the Califs in 870 A.D., near the site of the ancient *Bolbitinuni*, and at one time possessed a very large Oriental and European trade; but since the construction of the Mahmudieh Canal, connecting Alexandria with the Nile, its commerce has been absorbed by that port, the entrance to the R. branch of the Nile being obstructed by a bar of sand, which is frequently impassable by vessels. R. is built of red brick, and is celebrated for the beauty of its gardens and the salubrity of its climate. It was captured by the French in 1798, and repelled a British attack in 1807, but its fortifications are now insignificant. Pop. 15,000. For an account of the famous R. stone, discovered in 1799, see **HIEROGLYPHICS**.

Rosett's Wood is a handsomely veined East India wood of a lively orange-red colour, and close, hard texture. It is imported in logs about a foot in diameter, and is used on a small scale as a furniture wood. As yet it is not ascertained of what tree it is the timber.

Rose' Water is prepared by distilling rose leaves, fresh or pickled in brine, and water. Six pounds of pickled roses with one gallon and a quarter of water will yield one gallon of 'double distilled' liquid. R.-W. is employed in perfumery and pharmacy.

Rose' Window, a circular window with mullions and tracery springing from the centre.

Rose'wood, a valuable S. American fancy wood, of which the finest descriptions are now understood to be the produce of several species of large leguminous trees of the genus *Dalbergia*, chiefly *D. nigra*, called by the natives Jacaranda (q. v.). Inferior kinds are yielded by other trees, which also bear the name of Jacaranda in Brazil, notably three species of *Macharium*. For a long time the belief was current, based upon the authority of the French traveller and botanist Guillemain, that the true R. was obtained from two species of *Triptolema* (a sub-genus of *Dalbergia*); but according to Dr. Allemão of Rio Janeiro, confirmed by Mr. Bentham, the facts are as stated above. It seems strange that notwithstanding the length of time R. has been known to European trade and manufactures, and the large quantity of it annually imported, its botanical history should be so very obscure. Indian R. or Blackwood is *Dalbergia latifolia*, a large tree of dry forests in various parts of India. The heart-wood varies from deep brown to blackish-purple, with veins, streaks, and specks of white and purplish colour, and is fine-grained, strong, and heavy. When fresh sawn it has the agreeable smell of R., and is much valued for furniture and a variety of other manufactures. The timber of *D. sissoo* is also an excellent and beautiful furniture-wood, and is highly esteemed in India for all purposes where joint strength and elasticity are required.

R. of the best quality comes from Rio in half-round planks about 12 feet long and 18 inches wide. It is hard and heavy, close in texture, beautifully veined and figured in the grain, the dark parts affording a rich contrast to the purple red ground. Bahia furnishes a large supply of R. of the second quality, and inferior varieties are brought from Honduras and Jamaica. R. is a very valuable cabinetmaking timber, and is much used for drawing-room and library furniture.

Rosicrucians (Ger. *Rosenkreuzer*), a mystic brotherhood revealed to the outer world in the *Fama Fraternitatis R. C.* (1614), the *Confessio Fraternitatis R. C.* (1615), and the *Chymische Hochzeit Christiani Rosenkreuz* (1616), which last was acknowledged by, as the two former works were commonly ascribed to, Johann Valentin Andreae (q. v.). From them we learn that a German noble of the 14th c., one Christian Rosenkreuz, after long travel in the East, founded on his return a brotherhood of seven adepts, the R., and dying at the age of 106 was buried in their temple, the 'House of the Holy Spirit,' with the inscription on his grave—'Post CXX. annos patebo.' The laws of the order, thus made known in the fulness of time, were that its members should heal the sick gratis, should meet once every year in a certain secret place, should adopt as their symbol R. C. (i.e., *Rosa Crux*), or a rose springing from a cross (the device, be it observed, of Luther's seal), and should assume the habit and manners of whatsoever country they might journey to. It is now supposed that Andreae simply intended a hoax upon the credulity of the age, and that Christian Rosenkreuz and all the attendant mysteries were wholly the coinage of his fertile brain. However,

the hoax, if hoax there were, was taken seriously, and as early as 1622 societies of alchemists at the Hague and elsewhere assumed the title R.; while Rosicrucian tenets powerfully influenced Cabalists, Freemasons, and Illuminati, and were professed by Cagliostro and similar impostors. Even to-day a Rosicrucian lodge is said to exist in London, whose members claim by asceticism to live beyond the allotted age of man, and to which the late Lord Lytton sought entrance vainly. His novel *Zanoni* has popularised the subject of Rosicrucianism, and for minuter information reference may be made to Buhle's *Ueber Ursprung und Schicksale des Ordens der Rosenkreuzer* (Gött. 1803); and H. Jennings' *The R., their Rites and Mysteries* (Lond. 1870).

Ros'in is the residual product of the distillation of oil of turpentine from crude Turpentine (q. v.). If the distilling process stops short of the thorough expulsion of the water, *yellow R.* is the result; and if it is protracted till the residue is on the point of decomposition, *black R.*, called colophony, is obtained. Alcohol, ether, and the volatile oils are solvents for R. It is employed in making varnishes, soap, and sealing-wax, and also for caulking ships and rubbing the bows of violins. Yellow R. is likewise used in pharmacy as an ingredient in ointments, plasters, &c.

Ross, a Gaelic word signifying a headland or promontory, also an isthmus and a wood. It enters into the composition of numerous geographical names, chiefly in Scotland and Ireland; e.g., 'Ross-dhu,' 'Culross,' 'Ardrossan,' 'New Ross,' 'Muckross,' 'Rosscastle,' 'Roscommon,' &c. The Cymric *rhos* or *res*, 'a moor,' is seen in the 'R.' of Hereford, Penrhos, and Roskilly.

Ross (Cym. *rhos*, 'a moor'), a market-town of Herefordshire, on the Wye, 18 miles W.N.W. of Gloucester by rail, has a fine parish church, restored at a cost of over £3000, with a spire 208 feet high; seven fine chapels, a quaint 17th c. market-house, a corn-exchange (1862), Blue Coat School (1786), large board schools (1874), and a free library, with reading-rooms and recreation-grounds (1873). R. publishes two weekly newspapers, and has manufactures of farming implements, a brewery, tanneries, and salmon-fisheries, &c. Pop. (1871) 4589. Pope immortalised this town in his *Man of Ross*, the subject of which, the philanthropist John Kyrie (1637-1724), lived in an ancient timbered house (still shown as one of the lions of the place), and now lies buried in the chancel of St. Mary.

Ross, the name of a clan, called in Gaelic *Clan Rosich na Gille Andrar*, 'the offspring of the followers of St. Andrew,' to whose service and honour one of its early chiefs had devoted himself. The clan was one of eighteen that fought on Bruce's side at Bannockburn, and as late as 1427 could muster 2000 fighting men. The *Earldom of R.* dates from the middle of the 12th c., and its possessors were in the earlier period of Scottish history notable enough. Ferquhard, the second earl, called *Fearchar Mac an t-Sigart* ('Ferquhard, the son of the priest'), in the reign of Alexander II. crushed a Celtic revolt in the N., headed by a son of Donald Bane, and another of the Gallowegians in the S. (1235). He was the founder of the Abbey of Fearn in Ross-shire. William, the fourth earl, fought for Bruce at Bannockburn (1314), and signed the memorable letter to the Pope (1320), asserting the independence of Scotland. His daughter Isabel married Edward Bruce, brother of the Scottish king. He had two sons, Hugh and John, the latter of whom married a daughter of the Earl of Buchan, and received the half of her father's lands. Hugh fell at Halidon Hill 1333, and his son William left no male heir. But through the female line the succession was carried on till another female heir, Euphemia, Countess of R., becoming a nun, resigned the earldom to her uncle, John, Earl of Buchan, son of the Regent Albany. The marriage of her aunt Margaret, however, with Donald of the Isles, induced that formidable chief to assert a claim to the earldom, and led to the great Celtic insurrection that was crushed at Harlaw in 1411. On the death of the Earl of Buchan at the battle of Verneuil in France (1424), the earldom of R. reverted to the crown. James I. restored it to Margaret, widow of Donald. Her son, Alexander, Lord of the Isles and master of R., was a very conspicuous, turbulent, and treasonable character in the 15th c. In 1429, at the head of 10,000 clansmen from the Hebrides and the mainland, he wasted the crown-lands round Inverness, and burnt the town itself to the ground. Imprisoned in Tantallon for two years, he received a free pardon for all his

crimes in 1431. During the minority of James II. he was Justiciar of Scotland N. of the Forth. In 1445 he entered into a league with the Earls of Douglas and Crawford to destroy the influence and authority of the young king, but died in 1449 before he could carry out his evil purpose. This was partly accomplished by his son and successor, John, who joined Douglas in his rebellion against the crown, wasted the shores of the Frith of Clyde from Innerkip to Arran, but was finally compelled to make his submission to his sovereign. Received again into the royal favour, he remained apparently loyal till the reign of James III., when he opened negotiations with Edward IV. of England with a view to obtain that monarch's help in the complete conquest of the Highlands. The result was the forfeiture of his lordship of the Isles in 1476, while the earldom of R. was finally vested in the crown. John, however, was not absolutely disgraced. He was created a lord of Parliament, and was allowed to retain *territorial*, though not *sovereign*, lordship of the Isles. The Rosses of Pitcalnie, descended from Hugh R. of Rarichies, brother of the last earl, are the representatives of the ancient Earls of R.

Ross, Alexander, was born at Aberdeen in 1590, educated for the Church, became chaplain to Charles I., and master of the Free School of Southampton. He died in 1654. R., who had managed to gather a good deal of money in his lifetime, left, among numerous other benefactions, £200 to the town council of Aberdeen to found bursaries, and £50 to the Bodleian library. He wrote about thirty works in prose and verse, all of which are entirely forgotten, and such unquestionably would have been the fate of Alexander himself, in spite of his charities, had it not been for the couplet in Hudibras:—

'There was an ancient sage philosopher,
And he had read Alexander Ross over.'

Ross, Alexander, a Scottish poet, born in the parish of Kincaidine-O'Neil, Aberdeenshire, 13th April 1699, studied at Marischal College, and was successively parish teacher at Aboyne, Laurencekirk, and Lochlee, where he died 20th May 1784. His *Helenore, or the Fortunate Shepherdess, a Pastoral Tale in the Scottish Dialect, to which are added a few Songs by the Author*, was published at Aberdeen in 1768. The volume at once gave R. a place by the side of Ramsay, as a master of the native Doric, and time has not robbed his verses of their charm. *Helenore* has still her ardent admirers, while the simplicity, blythe-heartedness, and racy vigour of the songs, give unabated pleasure. The very titles of some recall delightful memories; *Wood and Married and a'; The Rock and the Wee Pickle Tow; and To the Begging we will go.* To the 5th edition of *The Fortunate Shepherdess* (Dundee, 1812) there is prefixed a memoir of the poet by his grandson, the Rev. Alexander Thomson, minister of Lintrathen, Forfarshire. The latest and best edition is that by Dr. Longmuir (1866), containing a sketch of R.'s unedited works.

Ross, Ludwig, a German philologist and archaeologist, was born of a Scottish family, at the paternal estate of Horst, in Holstein, 22d July, 1806, and studied at Kiel and Leipsic. In 1832 he set out to travel in Greece, and two years later was made conservator of antiquities at Athens. He held a professorship of archaeology in the University of Athens from 1837 till the revolution of September 1843, and in 1845 was appointed to a similar chair at Halle. By intense devotion to study he greatly impaired his health, and perished by his own act, 6th August, 1859. His chief works are *Inscriptiones mœtiae* (3 parts, 1834-45), *Denkm. von Attika nach Inschriften* (1846), *Handbuch der Archæologie der Kunst* (1841), *Reisen auf den Griech. Inseln das Ägäischen Meeres* (4 vols. 1840-52), *Italer und Græken* (1858), *Heilenika* (2 vols. 1846).

Ross, Sir John, K.C.B., a famous Arctic explorer, the fourth son of the Rev. A. Ross of Inch, was born at Balmacloch, in Wigtownshire, Scotland, June 24, 1777, entered the navy in his tenth year, and served gallantly throughout the French war, receiving, among other acknowledgments of his skill and courage, a sword worth £100 from the Patriotic Society, and another sword worth £200, with a knighthood from the King of Sweden. In 1818 he set out in command of the sloop *Isabella*, the consort of the *Alexander* brig under Sir W. E. Parry, for the purpose of exploring Baffin's Bay and searching for a N.W. passage. On his return in December of the same year he was advanced to post rank, and subsequently

he detailed the results of his investigations in *A Voyage of Discovery, made under the Orders of the Admiralty* (1819). In May 1829 he again set out for the Arctic regions in the *Victory* steamer, equipped at the expense of Sir Felix Booth. The *Victory* became ice-bound in the Gulf of Boothia in September 1830, and having made little further advance by May 29, 1832, was then abandoned, the party being rescued by a whaler in August 1833. R. was knighted in 1834, and received the gold medals of the London and Paris Geographical Societies, and various foreign orders. From 1839 to 1845 he was consul at Stockholm, and after a fruitless voyage in search of Sir John Franklin (1850-51), he attained the rank of rear-admiral. He died in London, August 30, 1856. His best-known works are *Letters to Young Sea Officers*; *Residence in the Arctic Regions*, &c. (1829-34); *Memoirs of Admiral Lord de Saumarez* (2 vols. 1832), and *Narrative of a Second Voyage* (1835). —**Sir James Clark R.**, nephew of the preceding, was born in London, April 15, 1800, entered the navy in 1812, and served in the Baltic and the White Sea under his uncle, whom he accompanied in his two searches for a N.W. Passage, on the second of which he made his famous discovery of the magnetic pole. He went with four Arctic expeditions under Parry (1819-27), was engaged in a magnetic survey of Great Britain and Ireland (1835-38), and commanded the *Erebus* and *Terror* expedition to the Antarctic Seas (1839-43), which reached latitude 78° 10' S., and collected a rich store of scientific data. He was knighted in 1844, and published *A Narrative of a Voyage in the Antarctic Regions* (in 2 vols. 1847). In 1848 he made a search voyage for Franklin in the *Enterprise*. He died at Aston House, near Aylesbury, April 3, 1862. A fellow of many societies, he received the founder's medal of the London Geographical Society, and from Oxford the degree of D.C.L. See D. M. Smith's *Arctic Expeditions* (T. C. Jack, Edin. 1877).

Ross and Cromarty, two counties of northern Scotland, now treated as one, owing to the intricate manner in which they are intermingled. They are bounded N. by Sutherlandshire, S. by Invernessshire, and stretch E. and W. from the North Sea to the Atlantic. Pop. (1871) 80,995. Their area is 3151 sq. miles, or 2,016,375 statute acres, of which in 1876 there were 47,413 under corn crops, 27,259 under green crops, 29,987 under clover, sainfoin, and grasses in rotation, and 19,395 in permanent pasture, exclusive of heath and mountain land. The principal crops are oats, barley, wheat, and rye. In 1876 there were in R. and C. 7099 horses, 41,609 cattle, 362,980 sheep, and 6535 pigs. Ross comprises the districts of Easter and Wester Ross, Ardmearach, or the Black Isle, Ardrross, Applecross, Fearmondal, Greinord, and the Island of Lewis in the Hebrides. Cromarty consists of a peninsula between the Firths of Moray and Cromarty, together with ten detached portions included in R. The high grounds afford excellent pasturage, and the soil of the valleys is generally fair. The valued rent in 1877-78 (exclusive of railways) was £270,426, and the valuation of railways was £21,777. To the W. and N. the country is very mountainous, the highest peak being Ben Wyvis, 3722 feet. The Oikill and Conon are the chief streams flowing eastward, while the Broom and Carron flow westward. The W. coast is broken by the great sea-lochs Broom, Greinord, Torridon, Carron, and Alsh. The beautiful Loch Maree is the most notable freshwater lake. On both coasts the geological formation is Old Red Sandstone, but the interior is composed of igneous rocks, chiefly granite and granitic gneiss. The mineral waters of Strathpeffer are in considerable repute, and there are several other mineral springs in the counties. The chief town is Dingwall.

Rossano, a town of S. Italy, province of Cosenza, in Calabria, 2 miles from the Gulf of Taranto, 93 miles S.S.E. of Taranto by rail. It has a castle and fourteen churches, among them a fine cathedral. There are quarries of marble and alabaster in the neighbourhood. Pop. (1874) 14,881.

Rossbach (Ger. 'Horse brook'), a village of Prussian Saxony, 9 miles S.W. of Merseburg, with some coal-mining. Pop. 689. It is celebrated as the scene of the brilliant victory of Friedrich the Great, with 22,000 men, over the combined French and Austrians, 60,000 strong, November 5, 1757. The Prussian loss was 300 men, that of the allies 1200 killed and 6000 prisoners. An iron monumental pillar on the field commemorates the battle, which was long known as the 'Rout of R.'

Rosse, William Parsons, Earl of, the celebrated British astronomer, was born at York, June 17, 1800. He graduated at Oxford in 1822, with first-class mathematical honours. As Lord Osmantown he represented King's County in Parliament from 1821 to 1831, succeeded to his father's title in 1841, and was elected one of the representative peers of Ireland in 1845. After 1830 he devoted his leisure to science, and especially to astronomy. At Birr Castle, where he chiefly resided, he set up his first reflecting telescope, which was furnished with a speculum of 3 feet diameter. The success of this instrument encouraged him to construct a second and larger telescope, having a speculum 6 feet in diameter. The speculum was moulded and polished by an improved method; and the instrument, 52 feet in length, was mounted at Parsonstown at a cost of £30,000. Though weighing twelve tons, it was so delicately poised as to be with great ease moved in any required direction. By its means, many nebulae, which had resisted Herschel's instruments, were at once resolved; and numerous new binary and ternary stars were discovered. Sketches of various nebulae were published in the *Philosophical Transactions* for 1850. In 1849 Lord R. was elected President of the Royal Society. He died at Monkstown, Ireland, October 31, 1867.

Rossetti, Gabriele, was born at Vasto, in Italy, March 1, 1783. In 1804 he went to study painting at Naples, and there also he developed his poetical tastes. Under Murat he became keeper of the Royal Museum; and during the disturbances of 1820 he gained great notoriety by his patriotic songs, one of which, beginning with the line 'Sei pur bello con gli astri sul crine,' stirred every village in Italy. The fortunes of his party being shattered in 1822, he hid himself for three months at Naples, and then escaped to Malta, disguised as a British naval officer. Two years after he settled in London as a teacher of languages, and in 1831 he was appointed professor of Italian literature at King's College. In 1826 he published in 3 vols. a *Commento Analitico* on Dante's *Divine Comedy*, in which he maintained that the mediæval poets all used a symbolism under which they expressed a hatred of the papacy. In defence of this theory he wrote *Sullo Spirito Antipapale che produsse la Riforma e sulle Influenze che esercitò nella Letteratura di tutta l'Europa e principalmente d'Italia* (5 vols. 1820). His doctrine on the subject was finally formulated in *Il Mistero dell'Amor Platonico Svelato* (1840); and the same idea permeates his commentary entitled *La Beatrice di Dante* (3 vols. 1852). The following are his poems:—*Dio e l'Uomo* (1840), *Il Veggente in Solitudine* (1846), *Poesie di G. R.* (1847), and *L'Arpa Evangelica* (1852). R. died in London, April 26, 1854. —**Dante Gabriele R.**, son of the preceding, born at London, 1828, was educated at King's College. He early devoted himself to the study of art, and with Holman Hunt, Millais, Madox-Brown, and others, he founded the school of Pre-Raphaelites which has asserted its principles with such wonderful vigour in spite of all the opposing tendencies of English painting. R., however, is almost the only member of the school who has adhered consistently to its severe canons. In 1850 he edited the *Germ*, a magazine devoted to the support of Pre-Raphaelism, of which the few numbers published are now highly prized. R. has never allowed his pictures to be exhibited at the Academy, and only visitors to the Grosvenor Gallery can enjoy any extensive acquaintance with his works. 'The Girlhood of the Virgin,' 'Ecce Ancilla Domini,' 'Dante's Dream on the Day of the Death of Beatrice,' 'A Christmas Carol,' are some of his most famous studies. In 1861 he published *Early Italian Poets*, rearranged in 1874 as *Dante and his Circle*. No more exquisite translations exist in our language than those contained in this volume. In conjunction with his brother William, R. edited Gilchrist's incomplete *Life of Blake* in 1863, and in 1870 his *Poems* appeared. All of these poems contain marks of inspiration, but also marks of the greatest care bestowed on their workmanship. Gautier's are scarcely more fastidiously finished. R.'s is a fine rather than a daring imagination; and in his use of quaint modulation and images he is like a musician drawing from some old and forgotten instrument its fullest strains. As a poet he has much in common with his friends Swinburne and Morris. His style is not so bold as that of the one, nor so rich as that of the other. He has not the charm of their voluptuous music; but he excels them in the delicate quaintness of his thoughts. —**William Michael R.**, brother of the preceding, was born in London about 1832. He is not a genius

like his brother, but he has done much service to English literature. In 1865 he published Dante's comedy, *The Hell*, translated into literal blank verse. He has likewise written *Criticisms on Swinburne's Poems and Ballads* (1866); *Fine Art, chiefly Contemporary* (1867), and edited one of the standard editions of Shelley, with Life, in 1869. He edited Walt Whitman's poems (1868) and Moxon's series of the poets; and the memoirs prefixed to the several volumes of that series have been collected under the title of *Lives of the English Poets* (1878).—**Maria Francesca R.**, sister of the preceding, born at London, February 17, 1827, devoted the greater part of her life to teaching. She published *The Rivulet*, a prose allegory, in 1846, *Idiomatic Italian Exercises* in 1867, and *A Shadow of Dante*, in 1871. She died 24th November 1876.—**Christina Gabriella R.**, sister of the above, born in London, December 1830, is one of the truest of England's poetesses. She published *Goblin Market, and Other Poems*, in 1862; *The Prince's Progress, and Other Poems*, in 1866; *Commonplace and Other Short Stories*, in 1870; *Sing-Song, a Nursery Rhyme Book*, in 1872; *Speaking Likenesses*, and *Aurora Domini, A Prayer for Every Day in the Year*, in 1874. Her *Poems* were collected in 1875. C. R. is a woman of the deepest spirituality, and, like her brother Dante, only writes as if after long thought. In her long pieces she is occasionally fantastical without being poetical, but some of her shorter poems for lyrical perfection must be compared to Tennyson's best. Of the latter kind is *Maudie Clare*, a poem in which it is impossible to detect a flaw.

Rossi, Count Pellegrino Luigi Odoardo, was born at Carara, 13th July 1787, studied law at Bologna, and at nineteen held the office of Procurator-General's substitute there. He was appointed Professor of Law at Bologna (1812). In 1816 he removed to Geneva, where he became Professor of Criminal Law (1819), Member of the Council (1820), and deputy to the diet (1830). Entrusted with a diplomatic mission to Paris in 1833, he was persuaded by Broglie and Guizot to settle in France, where he was at first employed in writing for the *Revue des Deux Mondes*, then naturalised, and was successively made professor of political economy and of constitutional law at the *Collège de France*, and a count and peer of France (1839). In April 1845 he was sent as ambassador extraordinary to Rome, where he persuaded Gregory XVI. to recall the Jesuits, and remained as ambassador till the Paris Revolution of February 1848. R. gained the confidence of Pius IX., who made him the head of the new ministry of the 14th September, in which he also took the portfolios of police and finance. R. had set before himself the high task of reconciling Italy, crushing or converting republicanism, and promoting a good accord with Austria; but his vigorous measures provoked some of his opponents, and he fell by the hand of an assassin on the 15th November 1848. His death was the signal for the outbreak of the revolution that drove the Pope to flight on the 23d November. R. wrote *Traité du Droit Pénal* (3 vols. Par. 1825); *Cours d'Economie Politique* (2 vols. ib. 1839-41, and 1843); *Traité du Droit Constitutionnel Français* (2 vols. ib.); a masterly *Préface à l'Essai sur le Principe de Population de Malthus* (ib. 1845); *Notes aux Œuvres de Ricardo* (ib. 1847); and a great number of articles in the *Revue Française* and the *Annales de Legislation et d'Economie Publique*. See Garnier, *Notice sur la Vie et les Travaux de R.* (Par. 1849).

Rossie'ny, a town of the government of Kovno, in European Russia, stands on the Dubissa, 88 miles N.W. of Kovno. It was formerly capital of the Polish province of Samogitia. Pop. (1870) 10,700.

Rossi'ni, Gioacchino, the most celebrated of Italian operatic composers, was born at Pesaro, in the Papal States, February 29, 1792. His father was a performer on the French horn, and his mother an operatic singer. He began to study music in Bologna in 1802 under D. Angelo Tesei. In 1816 he made a musical tour through the Romagna, and in the following year received lessons from Mattei at the Bologna Lyceum. The first opera he composed was *Demetrio e Polibio* (1809), but his earliest performed work was *La Cambiale di Matrimonio* (Milan, 1810). The *L'Inganno felice* (Vienna, 1812) and *La Pietra del Paragone* (Milan, 1812), were steps in advance, but his delightful *Tamcredi* (Venice, 1813) evoked a storm of genuine applause. His fame at once became European, and when little more than twenty years of age, he was the favourite operatic composer of the day.

Of the extraordinary series of thirty operas which he produced with amazing fertility during the next ten years we can only mention a few of the best, viz., *L'Italiana in Algeri* (Venice, 1813), *Aureliano in Palmira* (Milan, 1814), *Elisabetta, Regina d'Inghilterra* (Naples, 1815), *Il Barbiere di Siviglia*, the most popular of comic operas (Rome, 1816), *Otello*, a fine serious work (Naples, 1816), *La Cenerentola* (Rome, 1817), *La Gazza Ladra*, an extraordinary success (Milan, 1817), *Mosè in Egitto* (Naples, 1818), *La Donna del Lago* (Naples, 1819), *Maometto Secondo* (Naples, 1820), *Zelmira* (Naples, 1822), and the grand and classic *Semiramide* (Venice, 1823), his last work for the Italian stage. He married Mdle. Colbran, a primadonna in 1821, and became conductor of the Italian Opera in Paris in 1824. In this city he produced *Le Siège de Corinthe* in 1826, an improved edition of *Maometto Secondo*, but little else of much importance except his last and most earnest opera, *Guillaume Tell* (1829), which, notwithstanding an inferior libretto, is a fitting pinnacle to his fame. The remaining thirty-nine years of his life were as barren as his youth had been prolific; indeed, he wrote nothing more except his celebrated *Stabat Mater* (1832), more frequently performed than any other, the *Messe Solennelle* (1865), and a few musical trifles. He lived in Italy from 1836 till 1855, but afterwards principally in Paris. He died November 13, 1868, and was buried in Père-la-Chaise. R.'s operas number about forty, some half-a-dozen of which are still favourites of the first class. They are distinguished by melodiatic invention, skill in writing for the voice, and florid instrumentation. The rapidity with which he worked, and a certain contemptuous carelessness of rule, render his compositions of unequal merit, while his scoring is frequently defective. But his genius was exuberant, versatile, and brilliant. His range was wide, and whilst the vivacity of his style found a natural vent in opera buffa, it enlivened his efforts at opera seria. His influence on his art was great, particularly upon the Italian and French schools. See R., *sa Vie et ses Œuvres*, by Azevedo (Par. 1865); *The Life of R.*, by Edwards (Lond. 1869), and *Della Vita e delle Opere di G. R.*, by Silvestri (Milan, 1875).

Ros'ter (formerly *Rolster*, probably a corruption of *Register*), a list in the British army regulating the regimental, garrison, and other services of officers and men in rotation. The officers' R. for regimental duty is kept in the adjutant's office, the R. for brigade duty in the brigade-major's office. A R. is kept of the rotation in which troops are to proceed on foreign service.

Ros'tock, the chief seaport of the Grand Duchy of Mecklenburg-Schwerin, on the river Warnow, 44 miles N.E. of Schwerin by rail. The river here is only eight to ten feet deep, and vessels drawing a greater depth than this load and unload at Warnemünde, 9 miles N., and at the mouth of the river. R. is surrounded by walls with twelve gates, and with its numerous gabled houses rising to seven stories, and its many fine old buildings, it presents a peculiar and very mediæval appearance. Among its squares are the Neumarkt with the Rathaus, and the Blücherplatz, containing a statue in brass of Blücher, who was a native of the town. R. has six churches, the chief of which are the Marienkirche of the 13th c. (309 feet long, 115 feet wide, and 85 feet high); the Petrikirche, with a tower 430 feet high; and the Nikolaikirche, with a tower 340 feet high. The University, founded in 1419, has a library of 120,000 vols., and had, in 1878, 39 professors and 157 students. The chief industries of R. are cotton, linen, tapestry, machinery, vinegar and brandy manufacture, tanning, shipbuilding, straw-plaiting, iron-founding, and brewing. It has large fisheries, and important commerce in corn, wool, flax, and wood. In 1874 there entered the harbour 611 vessels of 64,738 tons, and cleared 600 of 67,345 tons. R. has the largest commercial fleet on the Baltic. Pop. (1875) 34,172. R. is of Wendish origin. Burnt by the Danish king Waldemar I. in 1161, it was rebuilt in 1170. From 1237 to 1301 ruled by a dynasty of its own; in 1323 it fell to Mecklenburg. It was a prominent member of the Hanseatic League from its commencement until 1630, and still enjoys many of its peculiar privileges. In 1695 it fell to Mecklenburg-Schwerin, and though taken by the Swedes in 1712, the Danes in 1715, and the Russian in 1716, was recovered in 1719.

Rostof, the name of two towns in European Russia. (1) **R.**, one of the most ancient towns in Russia, on the lake of R.,

government of Jaroslav, 34 miles S.S.W. of the town of that name. It has 33 churches, and is the seat of an archbishop. It has manufactures of linens, silks, and candles, and is the scene of an active trade during the great annual market (February 21 to March 11). Pop. (1870) 9683.—(2) **R.**, on the right bank of the Don, government of Ekaterinoslav, 34 miles E. of Taganrog by rail. The foundation of the fortress of St. Dmitri here in 1749 was the commencement of the town, which has increased rapidly, owing to its advantageous situation as a ferry over the Don. **R.** has 5 churches, and carries on an active manufacture of cast iron, bricks, tobacco, soap, and leather. In 1873, the value of articles imported was £174,600; of articles exported, £1,734,680. Pop. (1870) 44,453.

Rostop'schin, Feodor Vassilievitch, Count of, was born at Moscow, March 23, 1765, of a family tracing its descent from Genghiz Khan. Distinguished as a soldier and court official, he rose under Catharine and Paul to be first chamberlain and a general in the army, but in 1801 fell into disgrace through his open disapproval of the alliance with France. Appointed by Alexander governor of Moscow (1812), he raised for the defence of the town a body of 122,000 volunteers, but on the approach of Napoleon left the town with these and the greater part of the population. The burning of Moscow, laid at his door by Niebuhr and others, he indignantly denied to be his doing, imputing it to the enemy in *La Vérité sur l'Incendie de Moscou* (Par. 1823). It is certain that **R.** in leaving Moscow devastated his own rich estates near the town. **R.** accompanied Alexander at the Vienna Congress, after which he lived chiefly in Paris. He died at Moscow 18th January 1826. An incomplete collection of his works appeared at St. Petersburg in 1853.—His daughter-in-law, **Countess Eudokia Petrovna R. (née Sushkoff)**, born at Moscow January 4, 1812, published two novels, *On the Shore* (St. Petersburg. 1857), and *The Happy Lady* (ib. 1858), and a collection of popular poems (4 vols. ib. 1855-59). She died at Moscow, December 15, 1858.

Ros'witha (properly *Hrôthwith*, from the Old High Ger. *Hruodsuind*; Latinised *Hrotswitha* and *Hroswitha*), a German poetess, born 935 A.D. of a noble Saxon family, became a nun at Gandersheim about 980, and died there about the beginning of the 11th c. She wrote six comedies in Latin after Terence, a poem in Latin hexameters on the deeds of Otto the Great, eight 'legends,' &c. Her works were first published by Konrad Celus (Nurn. 1501); the last critical edition is that by K. A. Barack (Nurnb. 1852). Their genuineness has recently (1867) been challenged by Aschbach, and vindicated by Kopke (1869) in his *Ottotonische Studien*. There is a French translation of the 'Comedies' by Magnin, with an admirable introduction (Par. 1845). The best edition of the poem on Otto is that by Pertz in the *Monumenta Germanicæ Historica*. See also the Essays by Hoffmann and G. Freytag (Brest, 1839), and by Dorer (Aarau, 1857).

Rotation. Under Kinematics certain elementary theorems relating to **R.** have been pointed out. It remains to supplement these, and then touch upon the dynamical bearings of the subject. A rigid system which is under no restraint, has six degrees of freedom, three of translation and three of **R.**; in other words, it requires six conditions to fix it. If one point is fixed translation is impossible, and there remain only the three degrees of freedom of **R.**; that is to say, the system is at liberty to rotate round any of three arbitrary non-planar axes, and a **R.** round any other axis can be resolved into independent rotations round these. Fix a second point, or, what comes to the same thing, fix any line through the first point, and two other conditions of restraint are introduced, so that the system has only one degree of freedom, namely, **R.** round this line as axis. Fix any plane passing through this line, and the system is under complete restraint. **R.** is simply displacement, or a succession of displacements, made according to a certain law; and it is a theorem in the kinematics of **R.** that any displacement of a rigid system is equivalent to a translation together with a **R.** round some axis in the system. Now a **R.** and translation are equivalent to a screw motion or twist; and hence any displacement can be represented by a definite twist. Again, since there is no translation if one point be fixed, it is evident that, displace a rigid body (with one point fixed) how you will, there is always at least one line of particles which occupies the same position before and after the displacement. This line of particles, of course, passes through the fixed point,

and it is the axis round which the **R.** equivalent to the displacement takes place. If a body is rotating round any axis, the motion of every point must be in a plane perpendicular to this axis, and must be normal to the plane passing through the axis and the point. The velocity of any point depends upon the distance of the point from the axis, and is indeed strictly proportional to this distance, since the angular velocity of every point is the same. If we regard the axis as a vector or directed line drawn in the direction from which the **R.** appears positive, and of length proportional to the angular velocity, we may completely represent the **R.** by this localised vector or *rotor*, as it has been called. And now the ordinary theorems of composition and resolution of rotations may be thus enunciated. The vector resultant of the representative rotors of a number of independent rotations is the rotor of the resultant **R.**; and the resolved portion in a given direction of the rotor of a **R.** is the rotor of the resolved portion of the **R.** The complete analytical statement of the most general problem in rotations was first given by Euler. Assuming the body to rotate with given angular velocities under the action of given couples round three rectangular axes, he obtained a system of three equations involving as co-efficients of the variables the moments of inertia of the body round these axes. When no external force is acting, the analysis is much simplified; and there are three rectangular axes, known as the *principal axes*, passing through the origin, about which the mass is so disposed that **R.** round any of them generates no couple or precessional motion. The axis of **R.** is permanent and the **R.** is stable; while an initial **R.** round any other axis is accompanied by a continual shifting of the real axis of **R.** In other words, the body rotates round an *instantaneous axis*, passing through the origin. Such a **R.** may be conceived of kinematically as the rolling of a cone fixed in the body upon a cone fixed in space. Except for special cases, Euler's equations cannot be integrated. From the space (—) symmetry, and directed character of rotations, the subject is evidently peculiarly fitted for quaternion treatment. See Poincaré's *Théorie Nouvelle de la R.*; Thomson and Tait's *Natural Philosophy*, vol. i. (1867); Tait's *Quaternions* (1872), and Clifford's *Elements of Dynamics* (1878).

Rotation of Crops. Experience has shown that one crop after another of the same kind greatly reduces the fertility of all soils. It has also shown that one crop after another of a different kind does not materially impoverish the soil. From these two facts the deduction is fair that the fertility of the soil is best maintained by taking *different crops* after one another. Accordingly, in practice a limit is placed on the number of crops taken in succession of whatever kind, and this number and succession is called the **R.** of **C.** As the inorganic materials which enter into the composition of plants vary much in their nature and relative proportions, it is evident that a soil may contain those necessary for the growth of certain species, while it may be deficient in those required by others; and it is on this principle that the rotation is founded, those plants succeeding each other in rotation which require different inorganic compounds for their growth. That the same crops grown several years in succession in the same field will deteriorate in a marked degree, has been tested by taking the returns of the plant grown on the same and on different plots through a series of five years, the result showing a manifest advantage in shifting crops of 6 per cent. in beans, 14 in oats, 27 in potatoes, 33 in flax, 55 in barley, and 66 in turnips.

In all countries where particular attention has been paid to agriculture, the most advantageous succession of crops is generally known—necessarily depending upon local circumstances, such as the quality of the soil, and its fitness for particular crops, the wants of the farmer, and the special market demands of his neighbourhood, the scope for the maintenance of stock to produce a sufficient supply of manure, the facility for purchasing manure, &c. As the most universal rule, it may be laid down that every alternate crop should be consumed by animals on the farm, or an equivalent in introduced manure be supplied, and that, as much as possible, the plants which succeed each other should be botanically of different orders.

The exhausting power of various farm-produce in ordinary cultivation is thus tabulated by Mr. Stephens:—1, the *corn crops*, in the order of wheat, oats, barley, rye; 2, *flax*; 3, the *potato*; 4, the sown grasses, when made into *hay*, in the green state they

ought to be; 5, *pease* and then *beans*; 6, the *root-bearing* crops, in the order, carrots, parsnips, Swedish turnips, yellow turnips, mangold-wurzel, white turnips; 7, *vetches* and *clover* when cut, as also lucerne and sainfoin; 8, *sown grasses*, rye-grass and clover, when pastured; 9, *permanent pasture* of the natural grasses. The following conclusions may be drawn from the above data—namely, that the highest class of exhausting plants, such as wheat, oats, barley, and rye, should not follow in immediate succession; that the less exhausting plants, such as the green crops, turnips, mangold, cabbage, carrots, or potatoes, should intervene; that the tuberous and fusiform-rooted green crops, such as potatoes, carrots, parsnips, being the most exhausting, should be associated directly with fresh manure; that the round-rooted green crops, such as turnip and mangold, should also be directly provided with fresh manure, but will thrive with less than the preceding class of green crops; that forage plants, such as vetches and clover, may be regarded as substitutes for round-rooted plants, but being less exhausting may be placed further from the manure; that the pasture grasses, being the least exhausting of all crops, may be placed furthest from the manure, and the longer they remain in pasture the soil receives the greater amelioration.

The principles of R. of C. applicable to agriculture also govern the horticulturist. Crops in horticulture are made to follow each other according to two distinct plans or systems, which may be termed *successional* cropping, and *simultaneous* cropping; the former is generally followed in private gardens, and the latter in market gardens. Successional cropping is that in which the ground is wholly occupied with one crop at one time, to be succeeded by another crop, also wholly of one kind. Simultaneous cropping is that in which several crops are all coming forward at the same time. The object to be attained by a system of cropping is that of procuring the greatest quantity and the best quality of the desired kind of produce at the least possible expense of labour, time, and manure.

Rotatoria. See ROTIFERA.

Rotche, a genus of Auks or *Alcida*, of which the *Mergulus* (or *Cephus*) *melanoleucus* is a familiar example. This bird is also named the 'little auk' and 'sea dove.' It is found on the Arctic coasts, and is almost entirely oceanic in habits, rarely visiting the land save for the purpose of breeding. Its general colour is black with a white mark on each wing, whilst the under parts are also white.

Rothe, Richard, a German commentator, theologian, and preacher, was born at Posen, 28th January, 1799. In 1823 he became preacher to the Prussian embassy at Rome, where he worked along with Bunsen. In 1828 he was appointed professor of divinity at Wittenberg, and in 1837 ordinary professor and director of the new Theological School at Heidelberg. This position he exchanged in 1849 for that of professor and university preacher at Bonn, but returned in 1854 as successor of Ullmann to Heidelberg, where he died 20th August, 1867. R.'s first work was the *Neuer Versuch einer Auslegung der Paulinischen Stelle Röm. v. 12-21* (Wittenb. 1836). It was followed by *Die Anfänge der Christl. Kirche und ihre Verfassung* (Wittenb. 1837); his greatest work, the *Theologisch. Ethik* (3 vols. Wittenb. 1845-48, of which the first 2 vols. were republished in a completely new edition in 1867); *Zur Dogmatik* (Gotha, 1863); *Sermons and Stille Stunden* (1872); and *Entwürfe zu der Abendandachten über die Briefe Pauli an den Timotheus und Titus*. (Wittenb. 1876). R. was the connecting link between the great conservative school of Neander, Olshausen, and the rest, and the modern critical school of men like Schenkel and Holzman, being at once profoundly religious and keenly scientific in spirit. An interesting biography of him has been written by Nippold (Wittenb. 1873).

Rothenberg-an-der-Tauber, a small and ancient town of Bavaria, on the Tauber, an affluent of the Main, near the Würtemberg frontier, and 33 miles S.S.E. of Würzburg by rail. It was formerly a free town of the empire, and has walls still in good preservation. The most interesting buildings are the Gothic church of St. Jakob (1373-1453), the Gothic Rathhaus (1574-89), and the Romanesque chapel of St. Blasius, a remnant of an ancient ducal castle. R. manufactures woollens, paper, and gunpowder, and has trade in corn and cattle. Pop. (1875) 5772.

Rotherham, a manufacturing town in the West Riding of Yorkshire, 5 miles E.N.E. of Sheffield by rail, on the right bank of the Don, which here receives the Rother ('red river'). The town was incorporated in 1871. The cruciform parish church, in Perpendicular style, with a crocketed spire and fine W. front and clerestory, is said to have been founded by Thomas Scott, a native of R. and Archbishop of York (1480-1500). It was restored in 1875 by the late Sir G. G. Scott at a cost of £9000. Other buildings are St. John's (1864), in Early English, and St. Stephen's (1875), in Second Pointed style, a handsome Roman Catholic church (1843), a Congregational chapel (1867), with a spire of 130 feet, a hospital and dispensary (1871), a free grammar-school (founded 1584), and the Independent College, established in 1755, and rebuilt (1874-75), in Collegiate Gothic style, at a cost of £20,000. R. Park, a picturesque recreation-ground of 20 acres, 300 feet above the town, was opened in 1876, and a new covered market, to cost £6000, is now (1878) in course of erection. A five-arched bridge over the Don, with an ancient chapel built on the central pier, connects R. with the suburb of Masborough, for more than a century and a half the seat of celebrated ironworks, where Southwark, Sunderland, and Staines bridges were cast. In 1871 the local ironworks employed 2087 hands, the manufacture of steel 124, of brass 156, of engines and machines 319, of glass 227, of earthenware 254, and the coal-mines in the district 1937. R. publishes one newspaper, and had a pop. (1871) of 25,892. See *Notes on R. Ecclesiastical and Civil*, by J. Guest, F.S.A. (1878).

Rothesay, a royal burgh and favourite watering-place of Scotland, and capital of the county of Bute, is beautifully situated on the E. side of the island, and at the head of a splendid bay, 40 miles from Glasgow by steamer. It is built round the head of the bay, and on the steep, woody slopes of an encircling belt of hills. Near its centre stands R. Castle, formerly a royal residence, which dates from about 1100. It was given by Robert III., who died here, to his son David, with the title Duke of R. (a title still borne by the Prince of Wales), and was partly destroyed in 1685. The picturesque ivy-clad ruin, having fallen into a wretched state of neglect, was tastefully restored by the Marquis of Bute in 1874-75. R. has several excellent hotels, a large hydropathic establishment, an elegant aquarium (1875), a handsome promenade (extended in 1877), and a good harbour. It is visited by nearly all the Clyde steamers on their way to and from the West Highlands, and is a great resort of invalids on account of the singular mildness of the climate. Its charter as a royal burgh dates from 1401. Pop. (1871) 7800. The name R. means 'island of Rother,' the ancient name of Bute.

Rothschild, Meyer Anselm (Amschel), was born in 1743 at Frankfurt-am-Main, his father, a Jewish trader, keeping a shop with the sign 'Zum Rothen Schilde,' from which the family takes its name. Destined at first for a rabbi, he eventually exchanged the Talmud for a ledger, and acquired at Hannover a small capital, on which he married Gutle Schnapper (1755-1849), and settled as money-lender on his own account in his native city (1770). In 1801 the Landgraf of Hessen appointed him court-agent; a year later, he engaged in his first important operation, a Danish loan. When in 1806 the Elector (late Landgraf) of Hessen fled before the French, he entrusted to R. the care of his abandoned treasures; nor was the confidence misplaced. R. died 19th September 1812, having with the aid of his five sons established the foundations of a house which 'not only has attained unparalleled wealth and financial pre-eminence, but has also become famous for its munificent and almost unrestricted charity.' The third of these sons, Nathan Meyer, born at Frankfurt, 16th September 1777, came over to England in 1798 as his father's Manchester agent. First on the outbreak of the Peninsular War (1808) did his boundless resources reveal themselves to the mercantile world in the shape of remittances to the English forces; and by degrees his financial transactions, dwarfing those of Gideon or the Goldsmids, extended over the entire Continent, his own or his brothers' agencies arising in every capital of the Eastern and Western hemispheres. Though not the eldest, he came to be looked on as head of the R. firm, and in 1822 was created Freiherr von R. by the Emperor of Austria, two years after his appointment as Austrian Consul-General. He died at Frankfurt, 28th July 1836, and was succeeded as head of the English house by his eldest son, Baron Lionel Nathan de R. The latter, born

at Frankfurt, 22d November 1808, and educated at Göttingen, has signalled himself by his successful efforts for the removal of Jewish disabilities, being himself elected member for the city of London in 1847, but not assuming his seat till 26th July 1858, and holding it till 1874. His eldest son, Nathaniel Meyer, born 8th November 1840, succeeded his uncle Sir Anthony R., Bart., (1810-76), and has sat for Aylesbury since 1865. The English branch of the R. family is allied by marriage with the houses of Yorke, Fitzroy, and Primrose.

Of Meyer's other sons, Freiherr Anselm Meyer von R. (1773-1855), head of the Berlin house, was succeeded by his nephew Meyer Karl (born 5th August, 1820); Freiherr Salomon Meyer von R. (1774-1855), head of the Vienna house, by his son Anselm Salomon (1803-74), and he in turn by his youngest son Salomon, and Baron James de R. (1792-1868), head of the Paris house, by his eldest son Edmund (born 1826), who is known since the Franco-German war for his hostility to Prussia. See *Das Haus R., seine Geschichte und seine Geschäfte* (2 vols. Leips. 1857); vol. i. of Otto's *Buch berühmter Kaufleute* (2d. ed. Leips. 1870); and chap. xlvii. of Picciotto's *Sketches of Anglo-Jewish History* (Lond. 1875).

Rotiferæ (Lat. 'wheel-bearers'), a group of animalcules usually classified with the *Scolecida* or *Vermes*, and distinguished by an anterior ciliated apparatus for effecting locomotion. They were discovered by Leeuwenhoek about the end of last century. He observed them in the rainwater which had collected in one of the gutters of his house-roof. R. occur in both fresh and salt waters, and are readily obtainable for microscopic observation. The body varies greatly in shape, but most of the species exhibit traces of a jointed arrangement of their frames, and have a terminal appendage either in the form of a jointed tail (*Brachionus*), or of pincers or nipper-like organs intended to attach the body to fixed objects. The shape of the wheel-like ciliated disc also varies in different genera. In some it consists of two circular lobes fringed with *cilia*, in others it is oval, in some kidney-shaped; whilst in place of the disc, tentacles provided with *cilia* may exist. The first observers of the R. gave them the name of 'Wheel Animalcules,' from the idea that the ciliated discs actually revolved. This is now known to be erroneous; the discs are stationary, but the *cilia* bending rapidly in succession appear like movable discs. The R. have a complete digestive system, and in this, among other things, are superior to the *Infusoria*. A complicated apparatus of jaws, regarded by Mr. Gosse as homologous with the jaws of insects, is found. The nervous system consists of a single nerve mass or ganglion placed near the anterior extremity, the ganglion being very large relatively to the size of the creatures. The sense-organs consist of several *pigment-spots*, which may represent rudimentary visual organs, and of certain appendages subserving the sense of touch. There are no heart or blood-vessels in R., but a special circulatory apparatus occurs in connection with the so-called *water-vascular system*. This system appears to convey water throughout the body, and may be either excretory or respiratory in its functions, or may perform both offices. The *sexes* are situated in different individuals. The females are the most highly organised, the male R. as a rule wanting the digestive organs and other parts, and having only the generative apparatus well developed. The R. are highly productive, nearly 17,000,000 eggs being calculated to be produced by a single *Hydatina* in twenty-four days. The R. are noteworthy as illustrating the phenomena of *Dormant Vitality* (q. v.). A good classification of these animalcules is still a *desideratum*. Amongst the best-known genera are *Hydatina*, *Rotifer*, *Floscularia*, *Meliceria*, *Stephanoceros*, *Brachionus*, *Notus*, &c.

Rot of Sheep, a well-known disease caused by the presence of parasites in the liver and bile-ducts of these animals. It appears to be developed in marshy grounds, and in situations in which the eggs and larvae of the parasites are freely disseminated. The most noted outbreaks of the disease in Great Britain occurred in 1809, 1816, 1824, 1830, 1853, and 1860. The western and southern counties of England were chiefly affected in 1860. In 1872—a wet season—R. was also prevalent. The parasite which causes R. is the liver fluke, the *Distoma* or *Fasciola hepatica*. R. is known as *Cootie* in Dorset, *Iles* in Cornwall, and *Bane* in Somerset. The Germans name it *Egelsenche*, or *Die Fäule*. R. is most prevalent in spring. The eggs are transferred with the *fæces* to the meadow-lands. The eggs find their

way into water, and there undergo the primary phases of development. Sooner or later the larvæ, which are free-swimming creatures, become *encysted* within the bodies of freshwater snails. Ultimately escaping from their molluscan hosts, they pass into the body of the sheep along with the water used in drinking, and from the stomach enter into the liver and bile-ducts and their branches, where they become fully developed and mature. The affected animals are dull and inactive, the mucous membranes are white, and the sheep lose flesh rapidly; thirst is present, and diarrhoea is a common symptom; the wool may also drop off in patches, and dropsical swellings take place; the blood wants albumen, and the tissues generally are wasted. The liver, as the seat of the disease, presents a characteristic appearance; the ducts are full of flukes, the liver-tissue is thickened and unhealthy, and in some cases is disintegrated.

R. is difficult to treat. Affected sheep should be destroyed, but if the disease has only made little progress, the sheep may be removed to dry pasturage, and be supplied with nutritious food, along with sulphate of iron and common salt.

Rottenburg, an old town of Würtemberg, on the Neckar, 8 miles W.S.W. of Tübingen. In the Bischofshof, formerly a Jesuit monastery, is a valuable collection of Roman antiquities. Round R. hops are extensively grown. Pop. (1875) 6416.

Rotten Stone is a silicio-aluminous compound, found in Derbyshire and other localities, and used in a state of powder as a polishing material for soft metals and glass.

Rotterdam (dam of the *Rotte*), the second largest city and commercial centre of the Netherlands, and capital of the province of S. Holland, on the right bank of the Maas, and on either side of its affluent the Rotte, 16 miles inland from the North Sea, 36 S. by W. of Amsterdam by rail, and in ordinary weather 12 hours from London. It is a busy, thriving city, of quaint, picturesque appearance, known on account of the intricate network of canals (*grachten* or *havens*) by which it is intersected, as 'vulgar Venice.' Stretching along the Maas, which is here about a mile wide, it narrows in the N. towards the Delft Gate, forming a triangle. The Boompjes ('little trees'), a handsome quay 1½ miles long facing the river, is flanked by fine buildings, and shaded with a row of elms planted in 1615 and now grown to large size. The river here is about 40 feet deep, and the canals, three of which (*Louwe Haven*, *Oude Haven*, and *Nieuwe Haven*) are strictly arms of the Maas, are of sufficient depth to admit of vessels discharging in the very heart of the city. Numerous drawbridges (*ophaalbruggen*) span the canals, and a great dyke or embankment runs through the centre of the town, protecting the lower quarters (*Binnenstad*, 'inner town') from inundation during high tides. The high street or Hoogstraat extends along this dyke, while the finest part of the town, the *Buitenstad* ('outer town'), lies between it and the Maas. An immense railway viaduct, the connecting link between various Dutch and Belgian lines (completed 1877), traverses R. from N.W. to S.E., and is continued by a vast double-railed bridge across the Maas at Moerdijk. Among the more notable buildings are the Groote Kerk of St. Lawrence, a brick Gothic structure, dating from 1472, and containing several monuments of naval heroes (De Witt, &c.) and a fine organ; the town-house with handsome Corinthian colonnade; the hospital of Coolsingel, which has accommodation for some 250 patients; and an elegant pile of public buildings (telegraph, and post office and railway station), erected near the heart of R., and in connection with the viaduct in 1876. R. has also 15 other churches, a synagogue, a medical school, a scientific Batavian Society, and many benevolent and intellectual institutions. The Museum Boijmans with its valuable art treasures were destroyed by fire with the Schieland Palace in 1864. Itself a market for several articles of import, R. has a great transit trade, chiefly for the supply of Germany. There are 28 regular steam lines to England, 5 to Scotland, and 2 to Ireland, and some of the vessels of these lines carry important mails. In 1877 there were, besides a fortnightly line to New York and a monthly line to Java, various lines to ports in the Baltic, Mediterranean, &c., most of which employ large steamers built in England or on the Clyde. In 1875 there entered 2010 British vessels of 766,954 tons, and cleared 1978 of 755,867 tons. The total number of vessels that entered (1873) was 3828 (of which 91 were from the Dutch E. Indies), and of those that cleared 3889. Among the chief imports are coffee (in 1875, 1,363,300 bags), sugar (62,000 tons), cotton (183,783 bales),

petroleum (166,741 barrels), tea (75,500 chests), and tin (121,572 slabs). The new water-way of the Hock van Holland, first used by ocean steamers in 1872, has since been deepened to over 17 feet in its shallowest part at high water, and is now used almost without exception in preference to the entrance at Brielle. Only the very largest vessels enter by way of Brouwershaven, the Helvoetsluice, and the canal of Voorne. R. has 42 distilleries, 58 windmills (12 for wood-sawing), and 10 sugar-refineries, besides important manufactures of iron, soap, sail and hair cloths, cigars, vinegar, liqueurs, and jewellery. Pop. (1877) 136,230, of whom one-fifth are Roman Catholics, and some 4000 Jews. R. received municipal rights in 1272, and outtrivalled Antwerp in commercial prosperity about the end of the 16th c. The Spaniards took it by stratagem, and plundered it in 1578. Later it suffered during the French revolutionary wars, and from inundations in 1775 and 1825. In recent years the town has been extending rapidly, and an ordinary bridge for carriage traffic was constructed (1876-77), a few yards distant from the great railway bridge, to give communication with an industrial suburb, which a public company proposes to extend by the addition of large wharves, stores, and docks.

Rottlera, is a genus of about 20 species of shrubs or small trees belonging to *Euphorbiaceæ*, found in tropical Asia and Australia. By Muller the species are placed under *Mallotus*. From the surface of the fruit of *R. tinctoria* a red mealy powder is obtained, known in India as Kalama, Kapila podi, or Wurur, which is used as a purgative, an anthelmintic, and sometimes in cutaneous diseases. It is also largely used as a dye-stuff for silk—red, rose-pink, and orange being obtained from it, and, by additional processes, blue, black, and green. The bark serves for tanning, and the leaves and fruit are applied externally with honey against the bite of poisonous animals. The name R. is in commemoration of Dr. Rottler, an eminent missionary for nearly fifty years in India, and a good botanist.

Rottweil, an old town of Wurtemberg, on the left bank of the Upper Neckar, 16 miles N.W. of Tuttlingen by rail. It was a free town of the Empire down to 1802. It has well-preserved walls and towers, and from its old houses and antiquities has a mediæval appearance. The finest buildings are the Heilige Kreuz-Kirche, a Gothic structure (12th to 14th c.); the Kapellenkirche, with a Gothic tower of 1374; and the Hochthurm in the W. side of the town, 148 feet high. R. has an important corn market, manufactures cottons and woollens, and contains the gunpowder manufactory for Wurtemberg. Pop. (1875) 5547.

Roturier (Low Lat. *rupturarius*, 'one who cultivates a *ruptura*' or villain's land), in France, was the exact antithesis of 'noble,' being the title borne by those who held, not by knight's service, but by allodial tenure, and in modern parlance has the signification of 'plebeian.'

Roubaix, a town of France, department of Nord, 8 miles N.E. of Lille by rail, on the Canal de la Marq. It has over 300 cotton and woollen factories, besides silk, dye, and machine works, breweries, tanneries, &c.; and the exports in 1874 amounted to 35,872,240 francs. Pop. (1800) 8700; (1876) 83,664.

Rouble, Ru'ble, or Ru'bel (Russ. *rublyn*), a silver coin, the unit of the Russian money system. The name is derived from a word signifying 'cut off,' because about the 15th c. exchange was effected by means of bars of silver, from which pieces were cut off to represent smaller values. In 1839 the silver R. was made the lawful money of exchange in Russia. It is divided into 100 copecks, and its average value during 1876 was 2s. 6d. Besides the R., pieces of 50, 25, 20, 10, and 5 copecks are coined in silver, and in gold demi-imperials of 5 R. 15 copecks, and imperial ducats, double and quadruple ducats, of 3, 6, and 12 R. respectively. In 1843 a paper money was issued which until the Crimean War was at par with the silver standard, but afterwards became depreciated by about 25 per cent.

Rouen (Lat. *Rotomagus*, afterwards *Rodomum*), formerly the capital of the province of Normandy, now of the department of Seine-Inférieure, France, stands on the N. bank of the Seine, 87 miles N.W. of Paris by rail, and 74 miles distant from the mouth of the Seine by water. It is one of the most picturesque and historically interesting, as well as one of the most commercially important cities of France. Surrounded by handsome modern boulevards on the site of its former fortifications, its central parts are irregular and ill-built, with narrow

streets and wooden gabled houses. A stone bridge and a suspension bridge connect it with the *Faubourg St. Sever* (pop. 20,000), on the S. bank of the Seine, and it has five smaller suburbs outside its boulevards. The ecclesiastical architecture of R. is unrivalled. The cathedral of Notre Dame, constructed between 1207 and 1280, is a splendid though unsymmetrical Gothic edifice, with two towers in the façade of unequal height, and a central spire of cast-iron fretwork 487½ feet in height, completed in 1876 to replace an old wooden belfry dating from 1544, destroyed by lightning in 1822. It contains the tombs of Rollo, first duke of Normandy, and his son William Longsword. The cathedral is surpassed in beauty and harmony of design by the church of *St. Ouen*, founded in 1318. The tower over the transept (268 feet in height) is surmounted by a representation in open stonework of the Norman ducal crown. The church contains no less than 135 stained glass windows, and 3 remarkably fine oriel windows. Notable also are the churches of *St. Maclou*, with the grave of Richard Cœur-de-Lion; and of *St. Gervais*, in the abbey attached to which William the Conqueror died in 1087. The other noteworthy buildings are the *Hôtel de Ville*, containing a library of 110,000 volumes and 2960 MSS., together with a picture-gallery; the *Palais de Justice*; the *Beffroi de la Grosse Horloge*, erected in 1389; and the *Hôtel Dieu*. R. has been called the Manchester of France, from its great cotton manufactures, producing goods to the value of 80,000,000 francs annually, consisting principally of the checked and striped stuffs known as *rouenneries*. It has also manufactures of hosiery, silk and wool fabrics, hardware, and machinery. It is an important seaport, as its harbour can receive ships up to 400, and steamers up to 600 tons. Ships to the number of 3000, and of 600,000 aggregate tonnage, pass up the river annually. Its output is Quillebœuf, about 30 miles distant by land. Pop. (1876) 104,900.

R. was the ancient capital of the *Galli Velocassi*, and became an episcopal seat in the 3d century. It passed into the hands of the Franks in 597, and became the capital of the Norse settlers in 912. It was taken from the Norman kings of England by Philippe Auguste in 1204. From 1419 to 1449 it was again in the hands of England, but was finally retaken by Charles VII. Here Jeanne Darc was burned alive in 1431, in the square now called in her honour the *Place de la Pucelle*. In 1593 the city was besieged and taken by Henri IV. The revocation of the edict of Nantes in 1685 was a terrible blow to its trade, the population being reduced by emigration from 80,000 to 20,000. In the war of 1870-71 there were several battles in its neighbourhood between the French under General Faidherbe and the Germans under General Goeben. R. is the birthplace of Fontenelle, the two Cornelius, and the composer Boieldieu.

Rouge is an oxide of iron employed for polishing gold, silver, and speculum metal. It is carefully prepared from sulphate of iron in several ways. The ordinary method is to calcine the crystals in a crucible, thus driving off the sulphuric acid from the ferrous oxide, which becomes changed in the process to ferric oxide. With a dull red heat the latter acquires a scarlet colour and forms R. If the calcination be prolonged, the colour alters to a purple or black, and the oxide hardens, *rouens* being produced, which is employed for polishing brass or steel.

R. is also the name of a cosmetic used to brighten the complexion. The best variety is prepared from carmine, and commoner kinds from Brazil wood and the safflower plant.

Rouge Croix and Rouge Dragon. See PURSUivant.

Rouge-et-Noir ('red and black'), a game of chance at cards played between a banker and an unlimited number of persons at a table marked with four spots of a diamond shape, two coloured red and two black. The tailleurs shuffle six packs of cards together, which are then cut by one of the players, whereupon the principal tailleur draws several cards from the top one after another. When their points (the cards from the ace to 10 counting as they are marked, and the court cards 10 each) amount to at least 31 and not more than 40 he stops, and proceeds to draw a second parcel in the same manner. The first parcel is for the colour 'noir,' the second for the colour 'rouge,' and that of the two whose points are nearest to the number 31 wins. Thus, if the *noir* is 33 points and the *rouge* 35, those who have staked upon *noir* win. If the numbers are both 31 (which happens once in 44 times on an average), it is called a *refait de trente-un*, and half the player's stakes are for-

feited to the bank, or his whole stake is 'put in prison,' the next deal determining its fate. This is the only advantage possessed by the bank, and at some tables it is necessary in a *refait* of 31 that the last card should be black. When the numbers are otherwise equal, as 33 and 33, the deal goes for nothing. A player may stake his money upon *rouge* or *noir* by placing it on the red or black spots on the table, or he may stake it on two other chances, *couleur* or *inverse*, which are dependent on the success or the contrary of the colour of the first card turned up. If he stakes on *couleur* he wins if this colour (red or black) wins, if on *inverse* he wins if it loses. The leading systems of play most in vogue at R.-et-N. are called *martingale* and *paroli*. The former consists of doubling a stake each time while losing until recouped by a win, which would be infallible in its results were not the highest stake limited to £405, the lowest being 4s. By *paroli* is meant a system of doubling the next stake while winning, and of playing single stakes after losses. R.-et-N. is sometimes called *trente-un* or *trente-et-quarante*. It became fashionable about 1798 in France, where it was forbidden by law in 1838. It was also suppressed in Germany in 1872.

Rough Casting, a process of plastering usually adopted for the external walls of cottages and farmhouses to render them water-proof. It consists in dashing over the plaster, while wet, a fluid mixture of fine washed gravel, lime, and water, called rough-cast or pebble-dash.

Rouher, Eugène, was born at Riom, in France, November 30, 1814. In 1828 he entered the Angoulême naval college, but he afterwards devoted his attention to law, and was admitted to the bar of Riom in 1836. After the February revolution a profession of republican principles secured for him the representation of the Puy-de-Dôme. On the 30th of October 1849, he succeeded Odillon Barrot as Minister of Justice. In January 1851, he shared the fate of his colleagues in the cabinet, and retired from the Ministry. In April he again became a member of the Government. R. held the portfolio of justice from the 2d of December to 22d of January 1852, and on the 25th of that month he became vice-president of the Council of State. In February 1855 he was appointed Minister of Agriculture, Commerce, and Public Works, and in 1860 he prepared the commercial treaty signed by France and England. He succeeded Billault as Minister of State in October 1863, and for five years with consummate ability defended government measures against the attacks of Thiers, Favre, and other eminent antagonists. On January 19, 1867, when the Imperial letter was addressed to him regarding the *Senatus Consultum*, he resigned, but was shortly reinstated. He was by Imperial decree made president of the Senate on the 20th of July, 1869. After the fall of the Empire he retired to England, where he exerted himself in the cause of Napoleon. In February 1872 he was returned to the National Assembly for Corsica, and is still (1878) the leader of the practical and prudent Bonapartists.

Roulers, or **Rosselæ're**, a town of Belgium, province of W. Flanders, 19 miles S. by W. of Bruges by rail, with considerable trade in flax, and manufactures of linen and lace. Pop. (1873) 12,433.

Roulette (Fr. 'a little wheel') was one of the principal gambling games in Paris from the end of the 18th c. until it was put down in 1838. From France, like Rouge-et-Noir, it fled to Germany, and became one of the attractions of the spas—Ems, Homburg, Wiesbaden, &c. It has been forbidden by law in Germany since 1872, but it is still played to some extent in various places in Europe and America. R. is played between a banker and any number of the public at an oblong table covered with green cloth, in the centre of which is a round cavity with a movable bottom, in the circumference of which are 38 holes, painted alternately in black and red, with the numbers 1 to 36, a zero, and a double zero. The banker throws with one hand a little ball of ivory into the cavity, which he sets in motion by turning with his other hand a handle in the form of a cross. After revolving a number of times, the ball falls into one of the painted compartments, thus determining the winning number. A player may stake on any number or numbers he chooses, and for this purpose rectangles are inscribed on the table to the right and left of the cavity, with the numbers 1 to 36 in 3 columns of 12 numbers each, a black zero, and a red double zero. All who have staked win in proportion to the numbers they have

chosen; thus, if a winning player has staked on one number alone he wins 36 times his stake, if on two numbers 18 times, and so on. There are also six chances, on either of which one may stake—viz., *impair* (an odd number), *manque* (the numbers 1 to 18), *rouge* (red), *pair* (an even number), *passé* (the numbers 18 to 36), and *noir* (black). When all these chances are staked upon, and the ball falls into zero, a player's stakes are either divided between the banker and himself, or 'put in prison' for another trial, to see to whom they belong. The bank, with its large capital, and the slight odds the zeros give in its favour, is a certain winner in the long run, and a steady gain of 4 per cent. may be calculated on. Some tables have a single zero, the total amount of stakes returned to the winners being then 35 to 1. In some American tables 27 numbers are only used, which gives, of course, a greater percentage in favour of the bank.

Round, a composition for three or any greater number of voices. It consists of a series of melodies, all of which harmonise. The first voice leads off, and on the termination of the opening melody the second voice takes it up, and so on, each part chiming in in turn, and all singing the entire round independently from their various starting-points an indefinite number of times. The effect is often exceedingly pretty. The R. is a sort of canon, but differs from it inasmuch as it can only be sung at the unison or octave. When of an amusing description it is sometimes called a catch.

Roundelay, in music, a vocal solo in rondo form.

Roundels or **Roundlets**, in heraldry, are circular charges of common occurrence. R. are of two sorts, of metal represented by discs, and of colour represented by globes. A roundel or is named a 'bezant'; *argent*, a 'plate'; *azure*, a 'hurte'; *gules*, a 'torteau'; *vert*, a 'pomme'; *purpure*, a 'golp'; *sable*, a 'pellet'; *tawny*, an 'orange'; *sanguine*, a 'guze.' Another roundel, the 'fountain,' of two tinctures, *argent* and *azure*, is represented by wavy lines of those tinctures alternately drawn fesse-wise.

Roundheads, the nickname of the Cavaliers for the Parliamentarians, first publicly used, according to Rushworth (iv. 463) and Clarendon (i. 267), in December 1641, by one Captain David Hinc, who, drawing his sword, swore that he would 'cut the throats of those round-headed cropp'd-eared dogs that lawed against the bishops.'

Round Robin (Fr. *rond ruban*, 'round ribbon'), a document signed by a number of persons in the form of a circle, that no name may appear the first on the list. It was first used by French officers in remonstrances to their superiors.

Round Towers, **The**, of Ireland, were regarded by antiquaries of a former generation as relics of a primeval Baal worship, but are now clearly proved to be of post-heathen erection, some of the earliest standing on Christian graves (which accounts for their occasional divergence from the perpendicular), and the date of the building of several being expressly given in the *Irish Annals*. At the present day (1878) they number 76—there were 118 in 1800—and may be arranged according to style in four groups, extending from 900 to 1238. The earliest (*e.g.*, the towers of Lusk, Antrim, and Clondalkin) are built of unrounded field-stones, cemented with coarse gravel mortar; the next group (Cashel, Iniscaltra, and Monasterboice), of rounded stones, roughly hammer-dressed, laid with mortar in irregular courses; the third (Killala, Devenish, and Glendalough), of well-dressed stones, with excellent mortar and regular courses; the last (Timahoe, Ardmore, and Annadown) are of good ashlar, rather open-jointed, resembling in this the English-Norman work of the 12th c. And in this last group we find the regular round arch, carved corbels, and other Romanesque details. The R. T. were all built in connection with churches, not, however, as bellries (though afterwards employed as such), since large bells were not cast till after 1200, and not till then were campaniles erected. They were due to the incursions of the Norsemen, being meant, as Mr. Ruskin says of church-towers generally, 'for defence and faithfulness of watch.' Similar structures occur at Ravenna, Nivelles, Maastricht, and in some of the Alpine valleys, along with churches dedicated to St. Bridget, relics of the Irish missionaries St. Gall and St. Columban. Extra-Irish instances in Great Britain are the towers of Brechin, Abernethy, St. Patrick's in the Isle of Man, Barra in the Outer

Hebrides, &c.; while a church at Deerness in Orkney, with two R. T., was demolished by the proprietor in 1832. See vol. ii. of Lord Dunraven's *Irish Architectural Antiquities*, edited by Miss Stokes (Lond. 1877), and O'Neill's *Illustrations of all the R. T. of Ireland* (1876).

Roup. See AUCTION.

Rous, or Rouse, Francis, was born at Halton, Cornwall, in 1579, and educated in Oxford at Broadgate Hall, near Pembroke College. He represented Truro in several Parliaments during the reigns of James and Charles I. In 1640 he sat in the Long Parliament; and in 1643 was made a member of the Westminster Assembly, and Provost of Eton College. He was unfit for this post, and the Royalists nicknamed him 'the old illiterate Jew of Eton.' In 1645 the Commons ordered the publication of his metrical version of the Psalms, a work which forms the basis of the modern Presbyterian Psalter. R. was made a privy councillor, and entered the House of Lords in 1657. He died at Acton, near London, 7th January, 1659.

Rou'say ('Rolf's Island'), or **Rowsa**, one of the Orkney Islands, lying to the N. of Pomona, from which it is separated by a strait $1\frac{1}{2}$ miles wide. R. is 4 miles long by 3 miles broad, and is generally hilly. Pop. (1871) 860.

Rousseau, Jean Jacques, born at Geneva, June 28, 1712, was the son of a watchmaker, and lost his mother at his birth. His childhood was cared for by a sister of his father, and for two years he received instruction from M. Lambercier, Protestant pastor at Bossey, but the boy educated himself by the help of Plutarch's Lives, Tacitus, and Richardson's novels. In 1725 he apprenticed himself to a watch-engraver, from whom he received the cruellest usage, and when scarcely fifteen he ran off to wander through Savoy. Mme. de Warens, a lady of property, was his first protector, and introduced him to the hospital or college of catechumens at Turin, where he renounced Calvinism for Roman Catholicism. Leaving this establishment, he engaged himself as servant, first to the Comtesse de Verceilis, and afterwards to M. de Gouvon, equerry to the Queen of Sardinia. Next he appeared at Lausanne as a teacher of music, and in 1732 he unsuccessfully sought employment in Paris. It was after his return from Paris that Mme. de Warens installed him as bosom friend in her house at Chambéry, and for eight years he remained happy with her. Finding himself at the end of that time supplanted in his mistress's affections, he left her house, although pressed to accept the post of second favourite. He spent a year in Lyon, then went to Paris with a new musical notation, which failed to impress the public, accompanied M. de Montaigu to Venice as secretary, and in a rage fled from this employer back to Paris. He tried in vain to bring out *Les Muses Galantes*, a light opera, of which words and music were his own. His lively comedy *Narcisse* was produced at the Théâtre Italien, and he wrote several articles for the *Encyclopédie*, but for all this he received no remuneration. He gained, however, the acquaintance of such celebrities as Grimm, Diderot, D'Holbach, and Mme. D'Epinay, the last of whom in 1759 provided for him a villa near Paris called the Hermitage, where he formed a connection with an ignorant plain-looking girl called Thérèse le Vasseur. He ultimately married her, but their five children he cast upon the care of the Foundling Hospital. In 1749 the Academy of Dijon offered a prize for the best essay on the question, 'Whether the progress of Science and the Arts has contributed to corrupt or improve the morals of mankind?' R. inclined to an essay on the affirmative side. 'Take the negative,' said Diderot, and R. won the prize with the brilliant *Discours* which stands first in his collected works. In 1752 appeared his pleasant opera *Le Devin du Village*, and his *Lettre sur la Musique Française* exasperated all Paris by his attacking the French school of opera. Next year he published his *Discours sur l'Origine de l'Inégalité parmi les Hommes*. Soon after he broke with Diderot and his set, and retired to a small house at Mont Louis, near Montmorency. There appeared in succession *Julie, ou la Nouvelle Héloïse* (1760), *Lettre sur les Spectacles*, *Du Contract Social* (1762), and *Émile ou de l'Éducation* (1764). *Émile* contains R.'s celebrated plea for a return to a state of nature, and while aiming at civilisation and the promulgation of Christianity, throughout denies both. It was burned by order of government, while its author, denounced as an enemy of public morals, had to flee from France. After

being hunted from town to town in Switzerland, he crossed to England in 1766, on the invitation of David Hume. Vanity, the disease that embittered and put an end to his life, caused him to quarrel with Hume; and he went back to France in the following year. In 1770 he was permitted to return to Paris, on condition that he did not write on religion or politics. He wrote his *Confessions*, but published nothing. He died at Ermenonville, July 2, 1778. R.'s mind united all that is petty and mean in character with a great sympathy for suffering, an intense appreciation of nature, and a more splendid imagination than any other celebrity French literature possessed. He is not witty like Voltaire, but he is more elegant than his rival. His cardinal fault is an insincerity which, just when he seeks to convince, betrays himself unconvinced. Even his own life he treats in his *Confessions*, not as a history, but as a romance, begun with falsification of his mother's pedigree, and strewn throughout with lies. He is not a philosopher, but an enthusiastic sophist, who passed for more in a time when all the world was a stage, and all the men were actors. Strange that such a man, among such men, should proclaim the innocence and purity—the immaculate conception—of every human being! In order to give plausibility to this doctrine, he traces all evil to political institutions, apparently content to consider society a final cause. He has given the world no great truth; but he acted a Samson's part in pulling down the tottering pillars of error. His great work of destruction is now forgotten by most of his readers, who now regard him only as a prose poet, and master of style. His *Confessions* appeared in 1782. R.'s *Œuvres Complètes* have been repeatedly published, with additions to each successive issue. More than one appeared during his lifetime. The best edition is that by Musset-Pathay (26 vols. Par. 1823-27). R., like Voltaire, has created a library of literature. Nearly every great Frenchman has contributed something to the criticism of R. or the elucidation of his writings. His correspondence has also been carefully collected and edited at different times. See Morin's *Essai sur la Vie et la Caractère de J. J. R.* (1851); Saint Marc Girardin's *J. J. R., sa Vie et ses Œuvres* (2 vols. Par. Charpentier, 1875); and Morley's *R.* (1873; new ed. 1878), the best biography of this author in any language.

Roussillon, a former province of France, now constituting the department Pyrénées-Orientales. It was surrounded N. by Languedoc, E. by the Mediterranean, S. by the Pyrenees, and W. by Foix. It was ruled by independent counts of its own from 904 to 1172, after which it passed to Aragon. Taken by Louis XIII. in 1642, it was formally ceded to France by the Treaty of the Pyrenees in 1659.

Rove'-Beetle, or Cock'tail, a name applied to beetles belonging to the family Staphylinidae. The group is recognised by their long linear black-coloured bodies. The *elytra* or front wings are very short, and the antennae usually consist of eleven joints. Most of the species are small. They live under stones, among moss, and in ants' nests. They have the habit of turning up the tail when alarmed; hence their popular name 'cocktail.' The larvæ resemble the adult insects. *Staphylinus olens* is the common species.

Bovere'do, a town of Austria, in the Tyrol, beautifully situated in the Lägerthal, on both banks of the Leno, within a mile of its junction with the Etsch (Adige), 7 miles from the Italian frontier, and $14\frac{1}{2}$ miles S. of Trient by rail. The finest building is the Castello, in the Piazza del Podesta. Among the seven churches are those of San Marco, of the 15th c., and Santa Maria del Carmine, built 1768. R. carries on extensive paper-making and tanning, but is chiefly important as the centre of the silk trade in the Tyrol, a district which produces from Trient to Verona upwards of 120,000 lbs. of silk annually. It has sixty *filande*, at which the silk is wound from the cocoons, after which it is spun in the *filatoje*. More than 2000 persons are employed in this industry. In the neighbourhood of R. southern fruits and excellent red wine are produced. Pop. (1869) 9063. Near R. the Austrians sustained a defeat from the French under Massena, September 3d and 4th, 1796.

Bovigno, a town of Austria, on the Adriatic, on the W. side of the Istrian peninsula, 42 miles S.S.W. of Trieste by rail. It has two harbours, and is the seat of an active trade in oil and wine. It has also shipbuilding, and an extensive sardine and tunny fishery. Pop. (1869) 9564.

Rovigo, capital of a province of the same name in N. Italy, on both sides of the Adigetto, here crossed by four stone bridges, 27½ miles S.S.W. of Padua by rail. The town is surrounded by walls with towers and bastions. It has twelve churches, among them a still unfinished cathedral, two theatres, a fine picture-gallery in the Palazzo Comunale, besides a library of 70,000 vols. The handsome Assize buildings were erected in 1873. Pop. (1874) 10,749.

Ro'ving. See SPINNING.

Rovu'ma, river of E. Africa, rises in the mountains bordering the E. side of Lake Nyassa, and flows generally E.N.E. for about 200 miles, entering the Indian Ocean in a fine bay in 10° 40' S. lat., a little to the N. of Cape Delgado. Drs. Livingstone and Kirk ascended the R. in 1861 in a small steamer for 30 miles, and in 1862 in ship's boats for 156 miles, when they found its further navigation obstructed by rapids. Thirty miles higher up, at the confluence of the Liende, the principal tributary of the R., is the town of Ngomano ('meeting-place'), which has a considerable trade. Though free from a bar at its mouth, the R. is of small value as an artery of commerce, being navigable for only eight months of the year. For 8 miles above its mouth it flows through pestiferous mangrove swamps, which are succeeded for 80 miles by a healthy valley from 2 to 4 miles wide, and shut in by the edge of a table-land from 600 to 800 feet high. This valley is fertile and heavily timbered, but infested by the tsetse fly. Above the table-land the country through which the R. flows is a level plain, dotted with detached granite hills, and well peopled. Traces of coal exist at many points on the banks of the river, and Dr. Livingstone believed that a vast coalfield extends from it as far S. as the Zambesi.

Row, John, a Scottish reformer, was born near Stirling about 1525; studied at St. Andrews University, where he devoted himself to civil and canon law. In 1550 his reputation as a pleader was such that the Scottish clergy sent him to Rome as their agent and representative there. While in Italy R. took the degree of Doctor of Laws at the University of Padua. Returning to Scotland in 1558, he began to examine the doctrines of the Reformers, and in 1559 abandoned Catholicism. In April 1560 he was one of six ministers appointed to compile a *Confession of Faith* and the *First Book of Discipline*; became minister of Perth in July, and took part in the first General Assembly of the Reformed Church of Scotland which met at Edinburgh, December 20, 1560. He was conspicuous in all the ecclesiastical transactions of the time, and held the office of moderator four times. He also took part in compiling the *Second Book of Discipline*. R. died at Perth, October 16, 1580. By his marriage with Margaret Bethune, daughter of the Laird of Balfour, in Fife, he had eight sons, one of whom, also named **John** (born 1568, died 1646), was the author of a *Historie of the Kirk of Scotland*, extending from the year 1558 to August 1637, and continued by his son to July 1639. This valuable work was printed for the 'Wodrow Society,' and also for the Maitland Club.

Rowan or **Roan Tree**, **Quick'en** or **Wick'en**, **Mountain Ash**, are names applied to *Pyrus Aucuparia*, a moderate-sized graceful tree of the section *Sorbus*, in which it is distinguished by its pinnate leaves, its dense cymes of cream-white flowers, succeeded by globose two- to four-celled berries. In Britain it is common in woods and on hillsides, particularly in Scotland, where it ascends to an altitude of 2600 feet. It is also met with throughout Europe, in Siberia, and in some outlying stations, such as Madeira. Both the timber and the coppice wood are useful for various purposes where elasticity combined with strength is a desideratum, and the bark has been employed in tanning. A belief in the power of this tree against witchcraft and evil spirits of all kinds, seems to have been prevalent at a very early date. The name 'Mountain Ash' has been given to the R. from a superficial resemblance of its leaves to those of the Ash.

Bowe, Nicholas, an English dramatist, was the son of a serjeant-at-law, and was born at Little Barford, Bedfordshire, 1673. When twenty-five years old he produced a successful tragedy, *The Ambitious Stepmother*. In 1702 appeared *Tamerlane*, the play upon which R. prided himself most. His other pieces are, *The Fair Penitent* (1703, founded on Massinger's *Fatal Dowry*); *Ulysses* (1707); *The Royal Convert* (1708); *Jane Shore*, the best of his

tragedies (1713); *Lady Jane Grey* (1715). He only attempted one comedy, and that a failure, *The Biter* (1705). R. does not stir the passions deeply; he has little imagination, and his plots are conventional; he is read only for the sober taste of his stately verse. He likewise wrote two volumes of short poems, all very poor; and in 1709-10 he published *The Works of William Shakespeare*, revised and corrected, with an account of his life and writings. This collection in 7 volumes is the first real piece of Shakesperian editing. R. was a very handsome man, and a great favourite in society. On the accession of George I. he was appointed poet-laureate and surveyor of customs; the Prince of Wales nominated him clerk of his council; and the Lord Chancellor gave him the office of secretary for the presentations. He left behind him a good translation of Lucan's *Pharsalia*, printed in 1728. R. died December 6, 1718. He was buried opposite Chaucer in Westminster Abbey, and Pope wrote his epitaph.

Rowlock (pron. *rullock*) is the name applied to a contrivance on the wale of a boat, to hold the oar in rowing. It consists of two vertical pegs of wood or iron, or of a pivoted iron hook or stirrup, or simply of a notch cut in the wale.

Rowing. See BOATING.

Roxburgh Club, a society named in honour of the illustrious bibliomaniac John, third Duke of Roxburgh, who died in 1804, and whose splendid collection of early English literature was brought to the hammer in his Grace's house, St. James's Square, in May 1812. The sale lasted forty-two days. The Club was instituted to commemorate the sale, 17th June, of No. 6292, a Boccaccio of 1471, which fetched £2260, and of No. 6350, *The Recuyell of the Histories of Troy* (Caxton, 1471), which fetched £1060, 10s., the latter of which had been bought by the Duke himself about the year 1793 from William Laing, Edinburgh for £50. There were originally 31 members; in 1875 the number was 38, and the entire number of members since its formation has only been 114. A list of the publications of the Club is given in Lowndes' *Bibliographer's Manual* (Bohn) up to 1864. Since then one or two volumes have appeared annually. The publications are extremely rare, and chiefly of antiquarian interest, though some are intrinsically important as literature, and all more or less valuably illustrate the history, languages, and manners of England in the olden times.

Roxburghia cœæ is a very small natural order of monocotyledonous tall climbers, with broad leaves and axillary, large and handsome, but very fœtid green flowers. The few species of which it consists are natives of India and the Eastern Archipelago. Of *Roxburghia viridifolia*, the thick tuberous roots after being boiled and soaked in lime-water are candied with sugar, and taken with tea; their flavour, however, is insipid. The order is named after Dr. Roxburgh, a celebrated Indian botanist.

Roxburghshire, an inland county in the S.E. of Scotland, bounded N. by Berwickshire, E. and S.E. by Northumberland, S. by Cumberland, S.W. by Dumfriesshire, W. by Selkirk, and N.W. by Edinburgh. Area, 428,494 statute acres; pop. (1871) 53,974. The county measures 40 miles from N. to S., and 38 miles from E. to W. It is divided by its waters into several districts:—Teviotdale, the basin of the Teviot and its affluents, 500 sq. miles; Liddesdale, which forms the S.W. corner of the county, embracing the territory drained by the Liddel and its tributaries, 120 sq. miles; the district between the Gala and Leader streams, 20 sq. miles; and that situated N. of the Tweed included in the Merse, 25 sq. miles. The whole surface is undulating and diversified, rising gradually to the Cheviot Hills in the S., which reach in Cheviot a height of 2602 feet, and in three other summits more than 2000 feet. The chief formation is New Red Sandstone with trap interspersed. The soil in the W. part of the county is thin, but in the E. it is extremely fertile, while the high districts afford excellent pasture. In 1876 there were 51,077 acres under corn crops, 29,445 under green crops, 56,139 under clover and grasses under rotation, and 37,507 of permanent pasture. There were also 4588 horses, 16,763 cattle, 489,357 sheep, and 3960 pigs. The rental (including railways) is valued for 1877-78 at £439,860. The manufactures are centred in the town of Hawick (q. v.). Jedburgh (q. v.) is the county town; Kelso (q. v.), the most attractive and agreeable residence; while Melrose (q. v.) presents the most celebrated and lovely scenes. R. is pre-eminently the 'Border' county, and

is rich far beyond all others in legend and ballad. Its ruined abbeys still witness to the monastic magnificence of the past.

Roxbury, now part of Boston, U.S., 3 miles from State Street, has factories for soap, candles, beef-packing, india-rubber, rope and cordage, woollens, lead, organs, locomotives, watches, painted floorcloths, fire-engines, and phosphate; also gasworks, mills, tanneries, breweries, foundries, and the Whittier Machine Co. There are 36 churches, a nunnery, a charitable society, 2 national banks, 2 savings banks, and 2 weekly newspapers. Its hillsides are studded with fine villas, and it abounds in beautiful drives. R. was first settled in 1630, and in 1868 was annexed to Boston. Pop. (1870) 30,000.

Roy, William, an English officer, born in the parish of Carlisle, Lanarkshire, May 4th, 1706, was employed by government after the rebellion of 1745 in preparing a map of the Highlands, and afterwards of the whole island of Britain. His most important work was measuring a base line on Hounslow Heath, the first accurate measurement ever made in England. R., who had reached the rank of major-general in the army, died in London, 1st July 1790. R. was the earliest British geologist. His most important work, however, is his *Military Antiquities of the Romans in Britain*, published in 1793 by the 'Society of Antiquaries.'

Royal, in naval affairs, an epithet distinguishing the sail and mast above the top-gallant sail and top-gallant mast.

Royal Academy of Music. An institution known by this name was originated in London in 1720, but its sole work seems to have been the introduction of the Italian Opera. The founder of the present Academy was Lord Burghersh, subsequently the Earl of Westmoreland, an enthusiastic amateur, who, struck by the absence of a national conservatoire in this country, induced a number of brother spirits to join him in its projection in 1822. Its rooms were opened for the instruction of pupils in 1823, and it was incorporated by royal charter in 1830. The first Principal of the Academy was Dr. Crotch, and among its earliest professors were Clementi, Cramer, Sir G. Smart, Potter, Braham, Bochsa, Moscheles, and Sir Henry Bishop. Harmony and composition, singing, pianoforte, French, German, Italian, elocution, deportment, and all branches of instrumental music, are taught by a large staff of professors in the Academy, which is supported by an annual grant from Government, public subscriptions, and the fees of students. Students are recommended by the members and subscribers, and must pass a preliminary examination. They must attend the classes of harmony, composition, and sight-singing, and may choose any subject for their principal study. The fees charged are an entrance fee of £5, 5s. (returnable at the end of three years), and £31, 1s. annually, or £10, 10s. per term, except in the case of orchestral students, who pay £2, 2s. as entrance fee, and £15, 15s. annually. Extra fees are charged in certain cases. A number of scholarships are attached to the institution. The Academy, to which a musical library is attached, is situated in Tenterden Street, Hanover Square. A long list of distinguished teachers and composers have received their education within its walls, including Sir W. Sterndale Bennett, Principal Macfarren, Brinley Richards, H. C. Banister, W. G. Cusius, Arthur S. Sullivan, and many others. In 1877 the number of pupils was 302. See the *History of the R. A. of M.* by W. W. Cazalet (Lond. 1854).

Royal Burgh. See BURGHS.

Royal Family, Law Regarding. The Queen *regnant* is the holder of the crown by her own right. The Queen *consort* (see CONSORT) is the wife of the king; and should she be the survivor, she becomes the Queen *dowager*. The present R. F. consists of the Queen, her children, grandchildren, daughters-in-law, and her Majesty's first cousins. They have precedence of all peers and officers of the state, civil or ecclesiastical. The education of the heir to the throne is under the control of the sovereign. No member of the R. F. can marry without the sovereign's consent, unless he is twenty-five years old and give twelve months' notice to the Privy Council. Even then, if Parliament express disapproval, the marriage cannot take place. Any ceremony of marriage performed in contempt of these regulations subjects all persons abetting to the penalties of *Premunure* (q. v.). These are the leading provisions of the Royal Marriage Act, 12 Geo. III. c. 2; consequently the relationship entered into between the Duke of Sussex in 1793 and Lady

Augusta Murray, which would otherwise have been that of marriage, was by a court of law declared to be illicit; and the claims of their son, Sir Augustus D'Este, accordingly, were disallowed.

Royal Military Academy, Woolwich, an institution for the preparatory technical education of all officers in the Royal Artillery and Royal Engineers in the British Army, was founded by warrant of George II. in 1741. Admission is obtained by successful candidates in open competitive examinations in mathematics, modern languages, English, and geometrical drawing and geography. The course of study extends over two years and a half, after which Artillery cadets enter the army, and those of the Engineers proceed to Chatham. It embraces (1) mathematics, (2) fortification, (3) artillery, (4) military drawing, (5) military history, (6) French or German, (7) elementary chemistry and physics, (8) drills and exercise, these subjects being compulsory and other subjects being optional. Payment for students varies according to the rank and profession of the father, the lowest amount being £20 annually for the son of an officer in the army or navy who has died in service, and the highest £125 for the son of a private gentleman. The R.M.A. is under the presidency of the Field Marshal Commanding-in-Chief, and the control of a governor whose salary is £1500 a year. There are 20 professors and instructors, with salaries ranging from £350 to £700. The charge for the R.M.A. in the Army Estimates of 1877-78 was £30,252. For the history of the institution see the *History of the Royal Artillery*, by Captain Duncan. The regulations will be found at length in the Appendix to General Voyle's *Military Dictionary* (Lond. 1876).

Royal Society of Edinburgh dates from the year 1783, and may be regarded as a resuscitation on an extended basis of the Philosophical Society, which had been founded in 1739, but had latterly been living a half-dead existence. The proposal to establish a society for the investigation and discussion of subjects in science, art, and literature was made by Principal Robertson, the historian; and the first meeting of the Society was held in the College library on June 23, 1783. It meets every first and third Monday of each month from November to June for reading and discussing papers. These are published in the *Transactions*, the twenty-eighth quarto volume of which is in course of publication (1878). Abstracts of papers and obituary notices of deceased Fellows appear in the *Proceedings*, which have now reached the ninth octavo volume. In July, 1878, there were 393 ordinary Fellows and 58 honorary members. The admission fee of resident Fellows is £2, 2s., and the annual subscription £3, 3s., which is reduced to £2, 2s. after ten years' membership, and ceases altogether after twenty-five years. The president (1878 Sir William Thomson of Glasgow) holds office for five years.

Royal Society of London. This celebrated society, the oldest of the kind in Europe, with the single exception of the Academy of the Lyncei at Rome, sprang into existence about the middle of the 17th c., a period when unwonted interest began to be taken in chemistry, medicine, mechanics, mathematics, and experimental philosophy in general. To Theodore Haak, a German, the honour of suggesting the formation of the scientific club from which it was developed is attributed. This, a small circle of philosophic friends, began to hold its meetings about 1645, usually at Dr. Goddards' lodgings, and occasionally under Professor Forster's auspices at Gresham College. A sister club was formed a few years later at Oxford, where Drs. Wilkins, Wallis, and Goddard held appointments, but in 1659 this association merged into the larger one in the metropolis. A regular Society without distinction of creed or nationality was definitely established in 1660. Persons were sent to travel abroad, while others remained in London engaged in independent experiments, committees of experts were formed on special subjects, and the results were submitted to the Society at its regular weekly meetings. The membership was originally, but for a short time only, restricted to 55, exclusive of fellows of the Royal College of Physicians, and the professors of mathematics and natural philosophy at the Universities of Oxford and Cambridge. The subscription was fixed at 1s. weekly, with an entrance fee of 10s. Some of the questions which exercised this learned body in its early days are apt to provoke a 19th c. smile and a reminiscence of the proceedings of the Pickwick Club; but with earnest and patient labour the achievements of the Society became solid and

useful in a very high degree. In 1662 the body was incorporated as the Royal Society by a charter granted by Charles II., His Majesty and the Duke of York enrolling their names as members. A council of 21 members was appointed, and Viscount Brouncker was elected the first president. An abstract of the charter and laws will be found in Dr. Sprat's *History of the Royal Society*, published in 1667, when the Society numbered nearly 200 members. These were not remodelled till the year 1776.

The first number of the *Philosophical Transactions* was published on 6th March 1665, and this work, probably the most valuable repository of scientific research in existence, has been regularly continued since. The series to the year 1878 is complete in 168 quarto volumes. The Transactions, which contain a record of the labours of the Society and the papers read before them, are sent to numerous societies and institutions all over the world, while every fellow is entitled to a copy. The *Proceedings of the Royal Society* is a supplementary and smaller work. Begun in 1800, it has now (1878) attained its 28th volume. The *Catalogue of Scientific Papers* is also an important publication regularly issued by the Society. In this catalogue for the decade 1864-73 alone 100,000 titles of papers are to be found.

In 1701 the Society removed from Gresham College to Crane Court, in 1782 to Somerset House, and in 1857 to Burlington House, in a wing of which building it is now accommodated. Sir Isaac Newton was president for a quarter of a century (1703-27); and one of the first great public works undertaken by the Society was the publication of the philosopher's *Principia*. In the presidency he has been succeeded by a brilliant series of illustrious men. For many years the Royal Society was the sole depository of science in Great Britain, and the numerous bodies which were subsequently formed on special scientific subjects are undoubtedly its offspring. Since its institution it has ever been indefatigable and generous in the support of scientific research, investigation, and discovery. Its money and its instruments have been freely given to the service of knowledge. It has sent forth numerous expeditions to all parts of the globe, the most important in recent years being the voyage of the *Challenger* from 1872 to 1876, which travelled 69,000 miles in the pursuit of scientific and geographical information. It awards 4 medals—the Copley, Rumford, and two Royal medals—annually. It has also a donation fund, several trusts bestowed by private benefactors, and the control of a sum of £1000 annually voted by Parliament for scientific purposes. Government in 1876 resolved to increase this latter grant by an annual sum of £4000 for the term of five years.

The meetings of the Society are held every Thursday at half-past 8 P.M., from the 3d Thursday in November to the 3d Thursday in June. The anniversary meeting is held on St. Andrew's Day, when the council of 21 members and the officers are elected. Fifteen gentlemen, each of whom must be recommended by at least six fellows, are selected annually by the council from the list of candidates for admission, and recommended for election as fellows, the election taking place on the 1st Thursday in June. The entrance fee for a fellow is £10, and the annual subscription £4. The buildings in Burlington House contain a library of 30,000 volumes on the ground-floor, a gallery of portraits, and a collection of curiosities. The fellows numbered 561 on 30th November 1876. For the year ending this date the revenue of the Society was £17,805, 13s. 11d., and its expenditure £17,744, 15s.

Royer-Collard, Pierre Paul, a French politician and author, was born June 21, 1763, at Sompuis, department of Marne. He was educated at Chaumont and St. Omer, and at the age of twenty became a member of the bar at Paris. At the outbreak of the Revolution he embraced republican doctrines, and after the seizure of the Bastille he was appointed secretary to the first organised municipality; but ere long he was proscribed as a Moderate, and took refuge in Sompuis. He then engaged in correspondence with the Royalist council at Paris, and in 1797 he was sent to the Council of the Five Hundred by the department of Marne. On the creation of the Empire, R.-C. retired into private life. He devoted himself to study, read Pascal, Corneille, Bossuet, Racine, kept Milton continually by his side, and devoted himself to the common-sense philosophy of Reid. He seized on Reid's *Analysis of the Mind* as a powerful weapon against the sensational school, then too powerful in France. In 1811 he was appointed professor of philosophy in

the University of France, but in 1815 he resumed political life, and became deputy for Marne, Councillor of State, and President of the Commission on Public Instruction. In 1827 he succeeded Laplace in the Academy. In 1831 he led the discussion on the constitution of the Chamber of Peers, but was too moderate, too frigid, and too severe, to be influential with ambitious schemers. In 1842 he finally retired from politics. He died at Châteauneuf, near Saint Aignan, September 2, 1845. Little as he has left in the way of literature, the influence of his thoughts on men of his time was very great. Cousin and Jouffroy among others owed their teaching to him. R.-C.'s philosophical fragments are to be found in Jouffroy's edition of Reid. See Barante's *Vie Politique de R.-C.* (1861), Philippe's *R.-C.* (1861), and Lacombe's *Vie de R.-C.* (1863).

Roy Bareilly (Rai Bareilly), the chief town of the district of the same name in Oude, British India, on the river Sai, a tributary of the Ganges, 55 miles S.E. of Lucknow, and 73 N.W. of Allahabad. It has some trade by the river, which is navigable up to this town, where it is crossed by a brick bridge. Pop. (1869) 7092.—The district of R. B., which lies between the Ganges and the Gumti rivers, has an area of 1752 sq. miles; pop. (1869) 988,719. The crops are wheat and rice.

Rshév, a town of the government of Tver, in European Russia, stands on the Volga 80 miles S.W. of the town of Tver. It has nine churches, and carries on a considerable trade in fish, linen, and hemp-seed. Pop. (1870) 18,732.

Ruatán', Roatan', or Battán', an island of the Caribbean Sea, in the Bay of Honduras, 30 miles long by 9 broad at the widest part, was given up by the British in 1860 to the Republic of Honduras. R. is well wooded towards the W. level, and grassy, and the hills rise to about 900 feet. Good zinc ore is found, and the fertile soil produces plentifully all tropical fruits and vegetables. The value of the exports annually is about £5000, and of the imports £4000. R. was the rendezvous of General Walker and his filibusters in their attacks on Central America. Pop. about 2000 (200 whites).

Rubasse, the name given by the French lapidaries to a variety of rock crystal traversed by rose-coloured streaks. The finest varieties come from Brazil.

Ruba'to Tem'po (Ital. 'robbed time') is, in music, an alteration, according to the taste of the performer, of the length of certain notes, what is given to one note in a bar beyond its ordinary length being taken from another.

Rubefacients are medicines which are employed for the purpose of producing irritation, redness, and congestion of the skin so as to produce a temporary influence as the result of the large surface affected, and not of any permanent impression upon the nutritive acts of that surface. R. may cause disorganising inflammation if allowed to remain too long in contact with the skin. They are of great value when it is desirable to arouse or stimulate the system; and they are especially useful in cases of sudden, severe pain due to acute congestion of a part or to some internal irritation. The mildest R. are cloths wrung out of hot water, and hot cataplasms. If more powerful action is required, the hot cloths may be sprinkled with Turpentine (q. v.); or Mustard (q. v.) may be added to the cataplasm; and by such means all grades of intensity, from the mildest impression up to severe blistering, may be produced.

Rubens, Sir Peter Paul, the great Flemish 'colourist,' was born of an old Antwerp family, 29th June 1577. Records in the Antwerp archives trace the family through a long 'pedigree of toil' back to Arnold R., a tanner, in 1350. The father of the painter, Jan R., who had taken the degree of Doctor of Laws at Rome, became a magistrate of Antwerp, and was forced by the ascendancy of Philip II. and of Catholic power to seek refuge in Köln in 1568. He was engaged in diplomatic business by William the Silent, and for a disgraceful liaison with Anne of Saxony, wife of the prince, was imprisoned for two years, and eventually died at Siegen in 1587. R. was born at Antwerp, or Köln, or Siegen, according as we read a sentence in a letter written by his mother, the noble-hearted Maria Pypelinx. He certainly lived for about ten years in Köln, curiously enough, in the house which formed the last asylum of his great patron, Marie de Medici. After the father's death the family returned to Antwerp, and R., having served an apprenticeship with Verghet, a land-

scape-painter, and also studied under Van Noort, entered the studio of Otho Van Veen (Otto Venius) in 1596. In 1598 he entered the Guild of St. Luke, and two years later started for Italy. At Mantua he first became familiar with court life, and thence went to Madrid on his earliest diplomatic mission. Returning to Italy, he visited Florence, Venice, and Rome, and from the Eternal City was summoned in 1608 to the death-bed of his mother. On the solicitation of the Archduke Albert and Infanta Isabella, he settled at Antwerp, where his house soon became a princely museum of art. For Marie de Medici (1628-31) he adorned the Luxembourg with twenty-four illustrations of events in her life, finishing the series in Paris. He spent eighteen months in Madrid on the diplomatic service of the Infanta, but his visit to Castile is now remembered by his pictures, not by his protocols. In 1630 he concluded the peace between Charles I. of England and Philip IV. of Spain, and, while in London was knighted by the king, who presented him with a diamond hatband, and defrayed his expenses. In 1634 he completed the famous decorations for Whitehall, to pay for which Charles had to pawn jewels and melt royal plate. The amazing number of pictures ascribed to R. can only be accounted for by remembering that he himself seldom did more than design and finish, and that in their production he was assisted by a host of pupils, including Van Thulden, Vandyck, Snyders, and Jordaens. Incessant toil seems to have broken his constitution, and after suffering severely from gout, he died 30th May 1640. Temperate, scholarly, high-bred, and generous, R. paints almost without sentiment and pathos. When he gives expression, it is often disagreeable, sometimes shocking. If his hunting pieces are savage, there is an absolute delight in representing pain visible in such works as the 'Scourging of our Saviour,' 'Martyrdom of St. Lievin,' 'Brazen Serpent,' and 'Great Judgment.' But though never tender or imaginative, and often voluptuous, he rises at times through sheer creative energy and complete mastery of his art into the region of the sublime. Inferior only to Titian as a colourist, and to Raphael in fertile ingenious composition, he fails adequately to conceal his artifice, or rather distracts attention by the wonderful display of his artistic power. As Thackeray says, 'In R. I am admiring the performer rather than the piece.' His female figures are strangely unequal, some noble and stately, others marred by all the defects of the Flemish type. Among the masterpieces of R. are the 'Descent from the Cross,' 'Elevation of the Cross,' and 'Crucifixion of St. Peter.' To the student R. is known both as an etcher and an author. His centenary was celebrated at Antwerp in 1877. See the *Catalogue du Musée d'Anvers* (1857); Sainsbury, *Original Papers, illustrative of the Life of R.* (1859); Gachet, *Lettres inédites de R.* (1840); *Contributions to the Life of R. in the Edinburgh Review*, January 1863; G. F. Waagen, *Kleine Schriften* (1875); Ruelens, *R. Documents et Lettres* (1877); and Gachard, *Histoire Politique et Diplomatique de R.* (1877).

Rube'ola. See MEASLES.

Rubia'cea, an order of Dicotyledons now extended from its original limit so as to include the plants formerly classed under *Cinchonaceæ* and *Galiaceæ*, which makes it one of the largest orders of phanerogamia—numbering about 350 genera and 4500 known species. It is cosmopolitan, including all monopetalous plants with opposite leaves, interpetiolar stipules, stamens inserted in the tube of the corolla and alternating with its lobes, and having an inferior compound ovary. The properties of the order in general are tonic, febrifuge, and astringent. It furnishes valuable articles of materia medica, of domestic use, and of trade, besides yielding in some genera edible fruits. The wood of *Gardenia Fovis-tomentis* of Angola is of very fine grain, very compact, heavy, and of extraordinary strength. The tree itself is regarded by the natives (probably an inference from the strength of the wood) as a preventive against thunderbolts—hence the name given to it by Welwitsch.

Ru'bicon, a small river of Central Italy, falling into the Adriatic, which formed the southern boundary of Gallia Cisalpina, and whose passage by Cæsar in 49 B.C. with the words '*facta alea esto*,' was the signal for war between him and the Pompeians. The latest investigations identify it with the Pisciatello, immediately to the N. of Rimini.

Rubid'ium (Rb = 85), an alkaline metal, discovered in 1860 along with Cæsium (q. v.) by Bunsen and Kirchhoff, by means of

spectrum analysis. The spectrum of its vapour consists of one strong band in the red and two in the violet. In its physical properties it resembles potassium, and has even greater affinity for oxygen than that metal, taking fire spontaneously in the air. Its oxide *rubidia* (Rb₂O) is a powerful alkali, and gives rise to a series of salts isomorphous with the potassium salts. It is present in small quantity in mineral waters, in certain minerals such as lepidolite, lithia-mica, and felspar, and in the ashes of the beet-root and other plants.

Ru'binstein, Anton, a modern composer and pianist, was born at Wechwotynetz, near Jassy, November 30, 1829. He played at a concert at Moscow at the age of nine, and was sent a year afterwards to Paris, where he studied for a year and a half. R. settled in St. Petersburg in 1848, where he wrote *Dmitri Donski*, his first opera, produced in 1852. He founded the conservatory of music at St. Petersburg, of which he was for nine years director. For many years he has been known as one of the most powerful and brilliant of pianists, and his concerts in this country, and appearances in connection with the London Philharmonic, have been numerous. He visited America in 1875. R. has composed over 100 separate works, including operas, cantatas, symphonies, string quartets, and numerous pianoforte compositions and songs. Among them are the operas *Die Kinder der Haide* (Vienna, 1861), *The Demon* (St. Petersburg, 1875), *Die Macca-bæer* (Berlin, 1875), *Feramors* (*Lallah Rookh*) and *Nero*, the oratorio *Paradise Lost*, and the *Ocean and Dramatic symphonies*. In his works, as in his performances, he has two separate styles, one full of savage energy and strength, the other possessing an infinite charm of tenderness and sensibility. His younger brother **Nicholas** enjoys a high reputation in Russia as a pianist and composer.

Ru'brica (Lat. *rubrica*, 'red chalk,' from *ruber*, 'red'), in missals, breviaries, and the Anglican prayer-book, are rules for the conduct of divine service, formerly written or printed in red ink, at present more usually in italics.

Rubruquis, Guillaume de (the name was latinised from Rysbroek), born early in the 13th c., in Brabant, entered a Franciscan order and was sent by Louis IX. of France into Central Asia on an embassy to Sartch, son of Batû Khan of Kiptchak, a supposed Christian prince, whose assistance was required against the infidel in the Holy Land. With two brother monks he sailed from Constantinople for Soldaria, crossed the steppes between the Dnieper and the Don on August 2, 1253, reached Sartch, and posted on to the court of Batû, on the Volga. Batû sent him on to the Tatar emperor, Mangû Khan, whom he reached on the 27th December, and with whom he subsequently removed to Karakorum. The mission was entirely unsuccessful. R. returned through Armenia, Persia, and Asia Minor to Syria, arriving at Tripoli in August 1255. He was detained in a monastery at Acre, and there compelled to write an account of his travels. R. was still living in 1293. Both Hakluyt and Purchas give translations of R.'s book.

Ru'bus, a genus of almost always trailing shrubs or creeping herbs, representing the tribe *Rubceæ* of the natural order *Rosaceæ*. The leaves are alternate, simple, or compound, with stipules more or less adnate to the petiole; the flowers white or red, in terminal or axillary corymbose panicles, rarely solitary; the calyx broadly cup-shaped, deeply cleft into five persistent lobes; the petals five; the stamens numerous; and the drupes one-seeded, and crowded on a dry or spongy conical receptacle. R. is a genus in which great diversity of opinion exists regarding the limit of the species. *Rubi* are abundant in the N. hemisphere, rare in the southern. Of the interesting species, *R. idæus* and *R. Chama-morus* have already been noticed in articles RASPBERRY and CLOUD-BERRY; see also BRAMBLE and LEWBERRY. There still remain a number of other noteworthy

R. Arcticus.

species, of which the following are the most prominent. *R. lasiocarpus*, a spreading shrub, with round glabrous stems and red flowers, abundant in many parts of India, producing a black fruit, which is very good to eat. *R. Canadensis*—the Dewberry of N. America—a shrub of trailing habit, giving an early black fruit of excellent taste. *R. deliciosus*, an erect shrub from the sources of the Missouri, is an exceedingly handsome species, and has large, raspberry-like, grateful fruit. *R. geoides*, of the Falkland Islands, Patagonia, &c., has greenish-yellow fruit, resembling the Cloudberry, and of a very agreeable taste. *R. rosifolius*, native of the hot parts of Africa, Asia, and E. Australia, gives an abundant and long-continued supply of fruit of a large size. *R. trivialis*, of the southern United States, has large edible fruit; it thrives in dry soil, and is rich in tannic acid. *R. arcticus*, a small herbaceous species of cold northern latitudes, has a purplish-red fruit of fine flavour, much appreciated by the Swedish epicures; a syrup, a jelly, and a wine are made from it.

Ruby, a term applied to two distinct varieties of jewel-stones. The real R. is the blood-red pellucid variety of the sapphire, and is composed almost wholly of alumina. It is called the *Oriental R.*, to distinguish it from the less valued and softer spinel rubies, which contain a considerable percentage of magnesia, silica, oxide of iron, &c., along with alumina. The latter are named according to their various tints; thus, the scarlet spinel is called *Spinel R.*, the pale red or rose red, *Balas R.*, the violet red, *Almandine R.*, and the orange red, *Rubielle R.* Oriental R. ordinarily ranks next in value to the diamond, but when it exceeds 4 carats in weight of perfect quality, which is rarely, it is more highly prized than a diamond of equal weight. The true R. is found chiefly in the valleys and watercourses of Ceylon and Burmah, and the spinel rubies occur in the rivers of India, Ceylon, Pegu, North America, and also in Wicklow.

Rückert, Friedrich, born at Schweinfurt in Bavaria, May 16, 1789, proceeded from the gymnasium of his native town to Würzburg University (1805), and there studied philology with such success that later he could say, 'All written languages live for me.' Sickness forbade his sharing in the War of Liberation, or following up the career of *privat-docent* for which he qualified at Jena (1811). The air of home restored his health and stirred his poetic powers. These first found utterance in *Deutsche Gedichte* (1814), whose *Gekürzte Sonnette* have much of Körner's ring. In 1816 R. undertook the poet's corner of the *Stuttgart Morgenblatt*; a year later he travelled to Italy, where he made fast friends of Overbeck, Cornelius, and others of the 'Artist Commonwealth.' At Koburg, where he settled on his return, he met Louise Fischer, object of the melodious *Liebesfrühlings* (10th ed. 1876), and afterwards his wife (1821). Lyrics, scattered through almanacs and periodicals, extended R.'s fame in constantly widening circles, but the necessity of earning more than fame forced him to exchange the idyllic quiet of his Koburg life for a chair of Oriental languages at Erlangen (1826). Here, as poet and Orientalist, he published several excellent translations of Eastern poetry, the long didactic poem, or series rather, of Alexandrine verses, *Die Weisheit des Bramanen* (6 vols. 1836-39; 9th ed. 1875), and the Persian epic, *Rostem und Sohrab* (1838), besides preparing a carefully-selected edition of his works (1843; 19th ed. 1876), which alone fills 700 closely-printed pages. A residence at Berlin, whither a pension and privy-councillorship drew him in 1841, bore fruit in four singularly undramatic dramas, and in 1848 R. retired to his country estate of Neuss near Koburg, where, after eighteen years of whimsical seclusion, he died, January 31, 1866. His *Gesammelte Werke* (12 vols. Frankf. 1867-69) include, besides the poems cited above, the *Zeigedichte* (songs of the old war time), *Pantheon* (hymns, legends, and allegories), *Wanderungen* (scenes of foreign travel), and *Haus- und Fahrtlieder* (pictures of every-day life). R. wrote, indeed, too much, and the Horatian vaunt, *Exegi monumentum*, so often in his mouth, will probably prove true of few beyond his lyrical productions. Yet these alone mark him the greatest of German poets since Tieck and Uhland, alike by their exquisite harmony and a sensibility to the relations of the outer and inner worlds, which to the English reader recalls now Tennyson, now Wordsworth. R.'s Eastern translations and didactic poems are tedious from over-fidelity to their originals or models, not in sense only, but rhythm, rhyme, and mannerisms. See his *Life*,

by Beyer (1868), and Berger's *Nachgelassene Schriften F. R.'s und neue Beiträge zu dessen Leben* (Vien. 1877).—**Heinrich R.**, son of the preceding, was born at Koburg, February 14, 1823, and died, professor of German language and literature, at Breslau, September 11, 1875. From many valuable historical and philological works of which he was the author, may be selected *Annalen der Deutschen Geschichte* (1850), *Geschichte des Mittelalters* (1852), *Geschichte der Neuzeit* (1854), *Deutsche Dichtungen des Mittelalters* (4 vols. 1872-76), and *Geschichte der Neu-Hochdeutschen Schriftsprache* (1875). His *Kleinere Schriften* are appearing in a collected form (vol. i. 1877). See H. Schulze, *H. R. und das Dichterhaus zu Neuss* (Bresl. 1875).

Rudder, a flat, heavy frame of wood, hung upon the stern-post of a vessel, round which, as on an axis, it is turned by the tiller. When the R. is in a straight line with the keel, equilibrium is maintained; but if the R. be forced to one side, the resistance which it then offers to the forward motion of the ship calls into existence a pressure acting perpendicularly to the R. on the side towards which it has been forced. The part of this pressure resolved perpendicularly to the ship's length acts upon the stern so as to force it to rotate round the ship's centre of mass.

Ruddiman, Thomas, born at Raggel, in the parish of Boyn-die, Banffshire, in October 1674, proceeded at the age of sixteen to King's College, Aberdeen, where he graduated after four years' study. A year later he became parish schoolmaster at Laurence-kin. There he met Dr. Archibald Pitcairne, who procured him the post of assistant-keeper of the Advocates' Library, Edinburgh, with an annual salary of £8, which R. had to eke out by revising and correcting for publishers, keeping boarders, &c., and even in 1707 by commencing business as an auctioneer. He had, however, here ample opportunities for study, the first fruit of which was his edition of Volusenus's (Florence Wilson) *De Tranquillitate Animi Dialogus*. In 1709 he edited Arthur Johnston's *Latin Cantica*, and *Paraphrase of Canticles*, and in 1714 appeared the work which still keeps his name familiar, the *Rudiments of the Latin Tongue*. It went through fifteen editions in his lifetime. Some years before this the Faculty of Advocates had trebled his salary in order to retain him. His edition of the *Opera Omnia* of Buchanan (2 vols. folio) appeared in 1715, in which year he set up business as a printer. In 1728 he was made printer to Edinburgh University. In 1725 he brought out the first part of his greatest work, *Grammaticae Latinae Institutiones*, treating of etymology; and the second part on syntax in 1732. Stallbaum re-edited, and Freund in his *Lexicon* frequently refers to this work. In 1729 he became proprietor of the *Caledonian Mercury*, which he had printed since 1724, and in 1730 he was appointed principal keeper of the Advocates' Library. Nine years later he published a splendid edition of Anderson's *Diplomata et Numismata Scotiae*, and in 1751 his 'immaculate' edition of Livy in 4 vols. In this year his sight began to fail, and he had soon to resign the librarianship which he had held for nearly half a century. He died at Edinburgh, January 19, 1757. George Chalmers, the antiquary, wrote his life (1 vol. 8vo. 1794).

Ru'denture (Lat. *rudens*, 'a rope'), in architecture, a rope-like mass filling the flutes of a column to about one-third of the height of the shaft; also called a *cabie*.

Rüdesheim, a town of Prussia, 17 miles from Wiesbaden, province of Hessen-Nassau, on the Rhine, celebrated for its wine, known as *Rüdesheimer*. The neighbouring heights are studded with numerous ruined castles. Pop. 3197.

Rudolf I., of Habsburg or Hapsburg, founder of the imperial house of Austria, born at Limburg, May 1, 1218, was the eldest son of Albrecht IV., Graf von Habsburg, and Hedwig of Kyburg. The death of his father in 1240 gave him a large territory and the command of a considerable force, which he hastened to place at the service of Friedrich II., under whose eyes he gained his spurs at the battle of Faenza in 1241. By his marriage with Gertrude, daughter of Burchard, Graf von Hohenberg, his repeated feuds with his uncles, the Graf von Habsburg and the Graf von Kyburg, and his quarrels with the Bishops of Strassburg and Basel and the Abbot of St. Gall, he acquired so much territory that his dominions extended from Mt. St. Gothard to the Schwarzwald, from the Bodensee to the Vosges, rendering him the most powerful prince in the S. of Germany. His bravery and love of

justice caused the forest cantons to put themselves under his protection, Uri, Schwyz, and Unterwalden in 1257, Zurich in 1264. In 1273 he was elected Emperor, having purchased the acquiescence of Pope Gregory X. by his concession of all feudal rights over the temporal possessions of the Pope, and of the right of interference in internal ecclesiastical affairs in Germany. He now turned his attention to the consolidation of the imperial power, which had fallen into decay, the nobles having acquired most of the crown lands and dues. His most powerful enemy was Ottokar (q. v.), King of Bohemia, who refused to acknowledge his election, but who was defeated and slain in 1278. R. accepted the homage of Ottokar's son, Wenceslaus, for Bohemia and Moravia; but he stripped him of Austria, Styria, Carinthia, and Carniola, which he gave in fief to his own sons, Albrecht and Rudolf. He now devoted himself to improving the internal condition of Germany. He purified the administration of justice, organising an efficient system of police, and clearing the country of robbers. His measures were thorough—in Thuringia alone he put to death twenty-nine robber nobles, and razed sixty-nine strongholds. In the midst of this reformation he died, much regretted by his poorer subjects, September 30, 1291. See Lichnowski, *Geschichte Kaiser R.'s I. und seiner Ahnen* (Vienna, 1836), and Schönhuth, *Geschichte R.'s von Habsburg* (2 vols. Leipzig, 1843-44).—**R. II.**, German Emperor, the son of Maximilian II. and Maria, daughter of Karl V., was born July 18, 1552. At the age of twelve he was sent to the court of his uncle, Philip II. of Spain. In 1570 he returned from Spain, and in 1572 he received the crown of Hungary, and that of Bohemia with the title King of the Romans in 1575. He was elected Emperor, October 12, 1576. Indolent and vacillating in his imperial policy, he left all power to his ministers, whose corrupt and reckless measures both lost him the support of the Catholics and exasperated still more the Protestants, thus preparing the way for the Thirty Years' War. R. devoted almost his whole attention to alchemy, astrology, and astronomy, attracting to his court by his liberality many impostors, besides several learned men, of whom the most famous were Tycho Brahe and Kepler, who have commemorated his patronage in the name of the Rudolphine Tables. R.'s weakness in government having made his kinsmen apprehensive that he would diminish the influence of their house, the archdukes met in 1606, and formally acknowledged as its head Matthias, his brother, to whom R. was obliged, in 1608, to yield all his dominions save Bohemia. In 1609, R. granted the Bohemians religious freedom by a royal charter, called the *Majestätsbrief*, but they, distrusting his sincerity, shut him up in his castle at Prague, and (1611) invited Matthias, who accordingly entered the city in triumph, March 29, and proceeded to his coronation on May 23. R., stripped of all his states, was spared the humiliation of losing all that he retained of imperial power, its name and shadow, by his death, January 20, 1612. See Gindely, *R. II. und seine Zeit* (2 vols. Prague, 1863-65).

Rudolstadt, a town of Germany, in the principality of Schwarzburg-R., situated in a fine valley on the left bank of the Saale, 23 miles N.N.W. of Weimar by rail. Pop. (1875) 7638.

Rue is the genus that gives name to the natural order *Rutaceæ* (q. v.), and consists of herbs and undershrubs, natives of temperate regions of the Old World. The much-divided leaves are beset with small glands containing a powerfully-smelling, acrid, volatile oil. The flowers are yellowish or greenish, arranged in terminal corymbs or racemes. Common R. (*R. graveolens*), a native of the Mediterranean countries and the Orient, is a somewhat shrubby plant of a peculiar bluish or yellowish-green colour. It has long been cultivated in gardens, being formerly considered a safeguard against witchcraft, potent to ward off contagion, and employed in domestic medicine. The name of 'herb of grace' given to it (e.g., *Hamlet*, act iv. scene 5) is a pun upon R. as the name of the plant, and the word 'rue' as an equivalent of the 'repentance' necessary to secure God's grace. The smell of R. when fresh is very strong, and to many very obnoxious; yet the chopped leaves are sometimes eaten with bread and butter as a stomachic, and are frequently given to poultry for the croup. They also make a beautiful garnish. The materia medica preparation of R. is a pale-yellow, acrid, and bitter oil of a disagreeable odour, distilled with water from the fresh herb. It is stimulant and antispasmodic, and is given in hysteria, colic, and other convulsive disorders. Water or Meadow R., and Wall R., are old names given to *Thalictrum flavum* (now applied to the

genus), and *Asplenium Ruta-muraria*, on account of the rue-like, much-divided foliage.

Ruff (*Philomachus pugnax*), a migratory, *Grallatorial* bird, arriving in the fen-counties of England in April, and leaving in September. The name R. was given from the great development of the feathers of the neck in the male during the breeding-season. The bill is straight, and the first and second quills are the longest. The hind toe is very short, and is elevated on the tarsus. The male is of a black colour, mingled with chestnut, the abdomen being white, with a brown tint. The average length is 12 inches. The R. is pugnacious, and the male wages war for the possession of the female, or 'Reeve.' The birds are much in request in the fen districts for the London market. They are easily fattened, and hence are snared in great quantities.

Ruffe, or **Pope** (*Acerina cernua*), a little freshwater fish found in most English rivers, and attaining a length of five or six inches. It belongs to the perch family, and is of a light olive-brown above and silver white below. The fins are spotted with brown. The dorsal fin is single. The R. is readily caught, the bait usually employed being a red worm.

Rugby (in Domesday *Rocheberie*), a market-town of Warwickshire, on the Avon, 83 miles N.W. of London, and 29½ E.S.E. of Birmingham, is one of the principal railway junctions in the kingdom. The parish church of St. Andrew is now (1878) being rebuilt as a memorial to the poet Moultrie, its rector for forty years, and there are also two distinct churches, St. Matthew (1841) and Holy Trinity (1853), the latter a cruciform structure with a central spire 200 feet high. Other buildings are the townhall and corn-exchange (1858), a Second Pointed Roman Catholic church by E. W. Pugin (1864), and St. Mary's Convent, with 144 inmates in 1871. Iron-founding, brick-making, brewing, and the manufacture of cement, are the leading industries of R., which publishes two weekly newspapers. Pop. (1871) 8385.

R. School, founded in 1567 by Lawrence Sheriff, a London grocer, 'for the children of R. and Brownsover [his birthplace], and next for such as be of other places thereunto adjoining,' has risen under the headmastership of James (1778-93), Arnold (1828-42), and Temple (1858-69), the present Bishop of Exeter, to be one of the first Public Schools (q. v.) in England. In July 1878 it had 27 masters and 455 boys, besides 70 in the subordinate middle-class school opened last May. The 'pile of questionable Gothic,' as Moultrie terms the school buildings erected 1808-20, has been greatly improved and added to since the Tercentenary of 1807. Out of the fund then started, which in June 1878 amounted to £33,376, the chapel has been rebuilt by Mr. W. Butterfield—the porch, two western bays, monuments, and memorial windows only having been retained; a gymnasium and new schools have been erected, the latter comprising two natural science schools, six class-rooms, &c.; a library, reading-room, and art-museum are now building; and a new 'Big School' is to follow. A long list of distinguished Rugbeians (Abercromby, Landor, Macready, Clough, Hughes, Hodgson, Stanley, &c.) might be formed from Whittaker's *R. Register*, 1675-1867 (Lond. 1868).

Rugeley, a town of Staffordshire, on the Trent, 9½ miles E.S.E. of Stafford by rail, has a Roman Catholic church with a lofty spire (1863), a town-hall, mechanics' institute, and a free grammar-school. On June 26, 1878, the foundation-stone was laid of new Public Buildings, to be erected in Geometric Gothic, which comprise a market-hall (66 feet by 41 feet, and 40 feet high), an assembly room, and numerous public offices. Iron and brass foundries employ a large number of the inhabitants, and in the neighbourhood are extensive collieries. Pop. (1871) 4630.

Rügen, the largest island of Germany, lying in the Baltic, opposite the coast of Pommern, from which it is separated by the Strelasund, 1½ miles wide at its narrowest part. Area 362 sq. miles. Pop. 47,048. On every side it is indented by deep bays forming a number of peninsulas connected by narrow strips of land with the main body of the island, and of which the largest are Witton and Jasmund in the N., and Mönchgut and Zudar on the S. The surface is level in the W., but is hilly in the E. and interior, while the N. and E. coasts usually consist of bold chalk cliffs. On the E. coast of Jasmund is the Stubbenkammer

(Slav. *stopien* 'steps,' and *hamien* 'a rock'), a perpendicular rock 420 feet in height; and extending for 12 miles along the same coast, the Stubbenitz, a beech forest, having in its centre the Hertha-see, on the W. bank of which is the Herthaburg, a semicircular mound 50 feet in height, the traditional scene of the mysterious rites of the goddess Hertha (v. Tacitus, Germ. 48). R. has a fertile soil, and extensive fisheries along its coasts. The chief towns are Bergen (pop. 4000) and Putbus, a favourite sea-bathing place.

Ruhmkorff, Heinrich Daniel, a philosophical mechanician, was born at Hannover in 1803. In 1819 he went to Paris and was porter in Chevalier's laboratory. In 1839 he started business as a scientific manufacturer, and 1844 constructed an improved and convenient thermoelectric battery. After a lengthened series of experiments in magneto-electricity, he brought out his induction coil or inductorium in 1851, hence known as the R. coil. At the Paris Exhibition of 1858 he was awarded a prize of 5500 francs for his collection of scientific apparatus, and in 1863 he obtained a grant of 50,000 francs from Napoleon III. for his improvements in the galvanic battery. He died December 21, 1877.

Ruhn'ken, David, a celebrated German scholar, born at Stolp in Lower Pommern, January 2, 1723, passed from the Friedrichskollegium at Königsberg to the universities of Wittenberg (1741) and Leiden (1743), where he gained the favour of Hemsterhuis. R. was appointed Greek 'Lector' at Leiden in 1757, and professor of history and eloquence in 1761. He died May 14, 1791. His works are still valuable for their correct and elegant Latinity. Chief of these are his *Epistola Critica* (Leid. 1749-51; new ed. Leipz. 1827), and his editions of Timæus' *Lexicon Vocum Platoniarum* (Leid. 1755-89; enlarged by Koch, Leipz. 1833), and of *Rutilius Lupus* (1768), *Velleius Paterculus* (2 vols. 1779), and *Ilesychius* (the latter begun by Alberus). See Daniel Wyttenbach, *Vita Ruhnkenii* (Leid. 1799; new ed. by Fiotscher, 1846), and Rink, *F. Hemsterhuis und D. R.* (Königsb. 1801).

Ruhr, the most important affluent of the Rhine from the right side in Prussia, rises near Winterberg, flows W.N.W. through fertile valleys, and joins the main stream at Ruhrort after a course of 142 miles. It is an important channel of communication between the productive coal mines of the district and the Rhine.

Ruhr'ort, a town of Rhenish Prussia, on the Rhine, at the mouth of the Ruhr, 12 miles N.N.E. of Crefeld by rail. With the best harbour on the Rhine, it is capable of accommodating 400 vessels, while its quays are of great extent. It is the seat of an immense coal trade, besides commerce in wood, wool, and corn. The export of coal amounts to 125,000 tons annually, for the transport of which R. has 16 powerful tug steamers and 400 barges, some of which are upwards of 500 tons burden. Pop. (1875) 9053.

Rule Britannia, the maritime hymn of Great Britain, second only as a national anthem to *God Save the Queen*, was originally sung in the masque of *Alfred*, performed for the first time at Clifden, August 1, 1740, before Frederick, Prince of Wales. The patriotic words have been variously attributed to David Mallet and to James Thompson, the joint-authors of the masque. The grand soul-stirring melody is by Dr. Arne.

Rule of Faith is the ultimate authority to which Christians are to look for instruction as to what they are to believe. Very various opinions prevail as to what is the R. of F. Román Catholics hold it to be a divine revelation, which is partly written and partly unwritten; in other words, it includes Scripture and Tradition. But as ordinary people are unable to decide what is canonical Scripture and what not, what is divine tradition and what merely human, the Church is appointed by God to be an infallible teacher in these matters. Protestants hold that 'the Word of God, as contained in the Scriptures of the Old and New Testaments, is the only infallible R. of F.' Certain mystics reject all external authority, and hold their R. of F. to be an 'inward divine influence.' Rationalists hold that the only R. of F. is reason, which is the source and ground of all religious knowledge and conviction.

Rule of the Octave, a system of adding harmonies to the diatonic scale which is used as the lowest part. It was formerly much taught as a formula to students.

Rule of Three, a technical term for the arithmetical process by which a fourth proportional to *three given numbers* is found. From its great importance in commercial transactions, it has also been called the golden rule. See PROPORTION.

Rum, a kind of spirits distilled from the skimmings of sugarcane juice or molasses, or from the latter alone, mixed with water and a considerable proportion of *dunder*, or lees of former distillations. Fermentation proceeds for several days before the 'wash' is transferred to the still. The distilled spirit is commonly coloured with burnt sugar. The peculiar flavour of R. is due to butyric ether; other ethereal principles develop with age, imparting mellowness and improved flavour. *Pineapple R.* is simply R. flavoured with slices of pineapple. The alcoholic strength is about equal to that of brandy. The distillation of R. is generally conducted conjunctly with the manufacture of sugar in the W. and E. Indies, Guiana, Reunion, Tahiti, &c. Jamaica R. commands the highest market value. W. Indian produce comes almost entirely from that island, and the annual value of the exports range from £240,000 to £290,000. The imports of R. into the United Kingdom, during the year 1876, amounted to 10,395,335 proof gallons, valued at £1,073,707. British Guiana and the W. Indian Islands sent four-fifths of the whole quantity. 5,037,075 gallons were entered for home consumption, on which a duty of £2,554,260 was paid. R. is largely consumed in the navy; in the towns of Great Britain its general consumption is small and on the decline.

Rum, a mountainous, rugged, and barren island of the Hebrides, 15½ miles N.N.W. of Ardnamurchan Point, Argyshire, 8 miles long by 7½ broad. At Ben More the surface is 2320 feet above the sea; at Cresal, 1800. Of the area of 30,000 acres, only about 1800 are under cultivation. Pop. (1861) 73.

Ruma'nia, since 1861 a principality under Turkish suzerainty, but erected into an independent state by the Treaty of Berlin (July, 1878), consists of the two 'Danubian Principalities' of Moldavia and Wallachia, together with the Dobrukscha and the delta of the Danube. The two latter districts were annexed to it by the Treaty of Berlin, in return for the retrocession to Russia of the small part of Bessarabia which it had formerly held. Its boundaries are now—on the E. the river Pruth, the Kilia mouth of the Danube (separating it from Bessarabia), and the Black Sea; on the S., a line drawn from Mangalia on the Black Sea to the Danube E. of Silistria, and the course of the Danube (separating it from Bulgaria and Servia); and on the W. and N. the Transylvanian Alps and the Carpathians (separating it from Siebenburgen and Bukowina). Its area is now about 49,800 sq. miles, or almost that of England. The greater part of R. consists of rich, alluvial plains, but along the W. and N. there is much hill country and table-land, some of the peaks, such as the Negoi and the Surul, rising to about 7000 feet. There are four great passes leading through the Transylvanian Alps into Siebenburgen—the Vulkan, the Rother Thurm, the Törzburg, and the Tomös passes. Through the Carpathians the principal passes are the Borgo and Oitoz. The rivers are for the most part deep and sluggish. The Danube (q. v.), and its tributary the Pruth (q. v.), now form the boundary rivers. The principal Moldavian tributary of the Pruth is the Schischija. Rising in Bukowina, the Sereth (q. v.) flows through the whole length of Moldavia until it joins the Danube at Galatz, its chief tributaries being from the left the Berlat, from the right the Moldava, the Bistritz, the Drotusch, and the Buseo, the last flowing through Wallachia. The other rivers of the latter state are all tributaries of the Danube, the chief being the Jalomitza, the Argisch, the Aluta (which rises in Siebenburgen and flows through the Rother Thurm pass), and the Schyl. Along the course of the Danube, even from W. of the mouth of the Aluta, there are large marshy lagoons, the largest being the *Balta* lake, near the mouth of the Argisch. The chief towns of Wallachia are Bucharest (q. v.), Braila (q. v.), Giurgevo (q. v.), Kralova (q. v.), Fokshan (q. v.), Plojesti (q. v.); and of Moldavia, Jassy (q. v.), Galatz (q. v.), Piatra (q. v.), Berlat and Botochani.

Climate.—R. is subject to very severe cold in winter, as well as great heat in summer. Even on the plains the thermometer often stands at -28° F. in winter, while it rises to 99° F. in summer and autumn. The approach of winter is marked by N.E. winds, which sometimes reduce the temperature by as much as 30° in a day. In the marshy lowlands, malaria is at

some seasons prevalent, but the excessively high death-rate is probably due rather to lack of sanitary knowledge on the part of the inhabitants than to unhealthiness of climate.

Agriculture and Commerce.—R. is almost entirely an agricultural and stock-raising country. The forests, it is true, are extensive, covering altogether nearly 5,000,000 acres, but the timber trade is small. In 1872 there were 6,111,136 acres in grain crops, producing 8,531,288 quarters, principally of maize, of which the 'mammaliga,' which forms the staple food of the population, is made. There were 9,511,040 acres in pasture and meadow land, on which 1,886,990 cattle, 4,786,294 sheep, and other stock (pigs, horses, and goats) to the number of 1,575,775, are reared. There were 380,545 acres of gardens, 234,758 acres of vineyards (producing a very poor sort of wine), and 9,384,227 acres, or nearly one-third of the whole country, were waste. Agriculture is as yet extremely primitive, but is advancing. R. is reported to possess great mineral riches, but they are almost entirely undeveloped. There are three salt-mines in Wallachia and one in Moldavia, worked under a state monopoly, and producing annually about 87,386,000 lbs. of salt, not of the finest quality. Petroleum abounds on the sides of the Carpathians. In 1872 there were 400 wells at work, yielding annually about 1,254,000 gallons. The Régie Company, established in 1872, has a monopoly of the tobacco-growing industry for fifteen years, and in 1875 the crop was about 6,722,000 lbs. The consumption of tobacco in that year was about 4 fr. 15 centimes per head of population. The exports for 1872 were valued at £6,662,280, the exports of grain amounting to over £5,000,000, and of mineral products to £80,000, the remainder being composed of wool, hides, tallow, &c. Grain to the value of £560,000 was exported to England. The imports for the same year amounted to £4,373,111. Including the Kustendje-Tchernavoda Railroad in the newly-annexed Dobrukscha, there are about 800 miles of railroad in R. The main line runs from Suczawa, in the N. of Moldavia, by Roman, Fokshani, Plojeski, Bucharest, Pitesti, and Kraiova, to Orsova on the Transylvanian frontier, from which a line to Temesvar (opened June 1878) places Bucharest in direct communication with Vienna. There are branches from Bucharest to Giurgevo, from Buseo to Braila and Galatz, and from Galatz to Berlat.

Army and Finance.—The regular army consists of 36 battalions of infantry, with 716 officers and 18,652 men; 17 squadrons of cavalry, with 122 officers and 2174 men; and 12 batteries of artillery, with 112 officers, 2076 men, and 96 pieces of artillery. There is also a territorial army of about 43,000 men. Those who draw the highest numbers in the conscription are drafted into the latter; those who draw the lowest, into the former. The period of service, both active and in the reserve, is eight years. Those who have completed their term of service are enrolled in the militia, and there is also a national guard, consisting of the whole body of citizens between 37 and 46 years of age. The navy consists of 2 steamers and 6 gunboats, with 400 sailors. According to the budget of 1877, the revenue was £3,217,586, the expenditure £3,451,664, leaving a deficit of £234,078. The national debt at the beginning of 1877 amounted to £24,828,408.

Religion and Education.—The national religion of R. is that of the Greek Church. The Metropolitan of Wallachia is the Primate of R., and there is also a Metropolitan of Moldavia. R. is divided into six bishoprics. Besides the secular clergy, of whom there is one for about every 200 of the population, there are numerous monastic orders, the total number of monasteries and nunneries in the Principalities amounting to nearly 300. Education is not good, but is said to be improving. In 1877 there were 2014 village schools, with 2016 teachers and 52,246 pupils; and in the towns 234 schools, with 566 teachers and 27,285 pupils. There are 35 higher Government schools, and about 214 private schools. The Universities of Bucharest and Jassy have together 63 professors and 669 students.

Race, Language, and Literature.—There is some difficulty in distinguishing the component parts of the population of R. Moldavia and Wallachia are parts of the ancient Dacia (q. v.), which was conquered by Trajan, A.D. 107, and shortly after colonised by his orders. It is a point of honour with the Rumanians (who call themselves *Romuni* and their language *Romunie*), to believe themselves descended from these colonists of 'the divine Trajan,' as they even now call him in their legal documents. Their language is, in point of fact, of Romance origin, but has

been enormously modified, both *a priori* by the pre-existing dialects of the region, and *a posteriori* by Greek, Slavonic, and even Teutonic influences. There are two dialects, the Daco-Rumanian in Moldavia and the North, much tinged with Slav elements, and the Macedono-Rumanian in Wallachia and the South. More than a third of those who speak the Rumanian language live beyond the boundaries of the Principalities. In Transylvania there are 2,321,906 Rumanians, while S. of the Danube there are probably almost a million. There has been no census of R. since 1859, but at the end of 1873 the population was estimated as nearly as possible at 5,073,000, and it has probably remained almost stationary since. This estimate includes about 400,000 Jews and 200,000 gipsies. The literature of the Principalities is almost confined to popular ballads and tales, in which Wallachia is particularly rich. See Arthur Schott's *Wallachische Märchen* (Stuttg. and Tub. 1845), and E. C. G. Murray's *Doine, or the National Songs and Legends of R.* (Lond. 1875). There are now newspapers both at Bucharest and Jassy. For the language, see *Grammatica Daco-Romana*, by Johannes Alexi (Vienna, 1826), *Historia Lingue Daco-Romane*, by Laurianus (Vienna, 1849), *Dier's Introduction to the Grammar of the Romance Languages* (Lond. 1863), and Stanesco and Lazar's *Praktischer Lehrgang zur Erlernung der R. Sprache* (Pesth, 1867).

History.—It is not until the 10th c. that a people bearing the name of *Vlachs* (of Slavonic origin, but probably equivalent to the German *Wälsch*, Eng. *Walsh* = foreigners) make their appearance in history. For centuries before this the Principalities had been the scene of the unrecorded struggles of Goths, Huns, Slavs, Bulgars, and other tribes, so that the Vlach people was now an extremely composite race, spreading over both the Principalities and the surrounding provinces. They were probably not converted to Christianity until about the middle of the 12th c., and then through the agency of Slavonians, their ecclesiastical terminology being still Slavonic. It was not long after their conversion that they first began to suffer from the Moslem inroads. The present R. was overrun but not annexed by the Turks. By a treaty between the Voivod Mircea and Bajazid I., in 1391, Wallachia accepted the Turkish suzerainty and agreed to pay a yearly tribute of 10,000 ducats, Moldavia meanwhile remaining independent until the reign of Soliman the Magnificent. The conventions with the Principalities were systematically violated by the Porte, and in 1711 Moldavia concluded a treaty with Peter the Great of Russia, which did not, however, produce any permanent good effect. About 1716 the Porte placed the financial affairs of the Principalities in the hands of a number of Phanariote Greeks, and this rapacious class continued its legal extortions almost without intermission until 1853. In 1769 an unsuccessful attempt was made by the Principalities to place themselves under Russian protection, and in 1774 the Porte conceded the right of the Russian ambassador at Constantinople to exercise a sort of protectorate over them, from which point dates the legitimised influence of Russia in R. Napoleon's intrigues led to several vicissitudes in the fate of the Principalities. They were occupied by Russian troops from 1806 to 1812, and in 1808 Napoleon formally assigned them to Russia, confessing to the Austrian minister at Paris that he had merely done so 'in order to throw an apple of discord between Russia and Austria.' By the peace of Bucharest in 1812, Russia gave up all claim to R., but stipulated for Bessarabia. The Russo-Turkish war of 1828-29 led to a five years' occupation of R. by Russia. From 1834 to 1848 Russia and Turkey intrigued against each other for preponderance of influence in the Principalities, the population dreading them both equally. In 1848 a joint occupation by Russia and the Porte was agreed to, but this arrangement soon fell through. It was the Russian occupation under Prince Gortschakoff in 1853 that led to the Crimean War, which ended in the Treaty of Paris (1856) binding the Porte 'to preserve to the Principalities an independent and national administration, as well as full liberty of worship, of legislation, of commerce, and of navigation.' It provided at the same time for the raising of a national armed force. After considerable difficulty the Principalities obtained the consent of the powers to their consolidation into one province and under one Hospodar. The first Hospodar was a certain Colonel Couza, elected by the Moldavian Assembly at Jassy and the Wallachian Assembly at Bucharest in 1859. He reigned under the title of Prince Alexander John, and it was under his *régime* that the first joint parliament of the two Principalities met at Bucharest in 1862. He, too, promulgated
